17,470. "Automatic transformer-switch apparatus." A. Schlatter. Dated July 21st, 1897. In alternating-current transformer systems means are provided for cutting out the transformers when there is no load. An arrangement is shown which consists of a primary network, the secondary and the transformer of group of transformers. There is an auxiliary transformer for controlling the electro-magnetic switches. Differentially wound magnets and their armatures connected to levers carrying contacts are shown. A hook is carried by the lever, and engaging with a catch controlled by the electro-magnet. When a translator is put in the circuit a current flows from the transformer through the magnet coils, the armature is attracted, and the lever moved to complete the circuit so putting in the transformer and breaking the circuit of another transformer. When the circuit is again broken the magnet is no longer excited, and the lever falls again to its original position. This arrangement, with one magnet may be used with small consumption of current, but in larger installations additional magnets are required. These magnets successively come into action as the current increases, the first magnet being cut out but the lever being held down by the catch, &c. Where there are several transformers, each to be controlled separately, additional switches are employed. The lever is fitted with a tube containing a liquid, such as mercury, which prevents oscillation with slight changes of current. 5 claims.

17,471. "Improvements in electrical furnaces." C. D. Abel. (Siemens and Halske, Germany.) Dated July 24th, 1897. The acting surface of the electrodes are made conical or of wedge shape, in order that the materials may fall through the arc. Caking is prevented by flanges on the upper electrode, the regulating movements of which stir up the materials. In one form the flanges are on the iron supports of carbons at some distance from the main electrode, spaces for the escape of gases being thus provided. Otherwise the powdered materials may be moulded with pitch or other substance into blocks, between which the gases evolved can escape. The fused product may be discharged through a hole in the lower electrode, a block at some distance below retaining the unacted-on materials. Or some of the product may be allowed to solidify on the lower electrode so that it forms a receptacle for the fused product, which may be tapped by boring from one side or below, the lower electrode being arranged to permit this. The lower electrode may consist of sloping plates, outside of which are combustion chambers for preliminary heating of the furnace. 7 claims.

17,523. "An improvement in or relating to coin-freed electrical meters." F. J. Beaumont. Dated July 26th, 1897. The current flows through a sector which is gradually turned by the meter until it leaves the terminal and makes contact with the terminal, so directing the current through a resistance which diminishes the light as a warning that the current is about to be cut off altogether. 3 claims.

25,078. "Improvements in and connected with the electrical propulsion of barges and boats on canals and rivers." H. W. Hancock and A. H. Dykes. Dated October 29th, 1897. Screw propellers, rudders, driving gear, electric propulsion, supplying currents for: detachable propelling barge. Relates to means for propelling boats and barges on canals and rivers after the manner described in specification No. 22,276, A.D. 1897. A frame carrying an electric motor is secured to a buoyant rudder, consisting of a hollow blade carried in a frame, and pivoted so that the variable draught of the vessel has no effect upon it. Propeller shafts journalled in the frame, carry screw propellers driven from the motor by sprocket wheel gearing. The current is supplied from the main wires by a trolley and connection. A switch on the tiller regulates the speed of the motor. In a modified arrangement, the propelling device may be carried on a detachable propelling barge, and a cover may be placed over the screw propellers to render the depth of immersion more uniform. Paddles or hydraulic propellers may be used instead of screw propellers. 4 claims.

25,205. "Improvements in coin-freed electric shock machines." G. Poore. Dated October 30th, 1897. Coin action, electricity, administering; fraud preventing. The coin dropped down a shoot enters a loop which extends from an arm over a pair of curved shelves. The arm is provided with a handle for turning it, but is normally prevented from more than a certain amount of play by means of a detent. Owing to the play the coin disengages the detent, and the handle can be turned till a contact arm turning with it reaches a stationary contact. The coin falls out of the loop when clear of the shelves, but the operator receives the current so long as he holds the aforementioned handle and a similar one by turning which the core of the induction coil is shifted to modify the shocks. Coins of insufficient size fall between the shelves. 1 claim.

25,245. "An improved method for varying the speed of electric motors or the electromotive force of dynamo electric machines." H. H. Lake. (E.Cantano, Italy.) Dated October 30th, 1897. Relates to a method of varying the speed of electric motors or the electromotive force of dynamo electric machines by varying the air space between the armature and the field magnets. The pole pieces are connected by a sliding dovetail joint to the magnets. The pole pieces are moved towards or from the armature by right, and left-handed screws on a shaft operated by a wheel. The specification also describes a small motor in which the induced armature may be moved towards or from the inductor coil by means of a movable screw head attached to the armature shaft by ball bearings. 2 claims.

THE SOUTH STAFFORDSHIRE POWER SCHEME.

THE South Staffordshire power scheme has entered upon a new stage of its somewhat chequered career in being bought up by a company, which has Mr. Atherton for its principal backer. As some of our readers well know, this gentleman has come much to the front of late in connection with the British Insulated Wire Company, of Prescot, and we may now confidently expect that there will be a rapid development of the powers which the Transmission Company undoubtedly possess. South Staffordshire is practically one huge town, and the multitude of small and varied industries which will always be carried on, combined with the proximity of all raw materials, makes this area one of the most promising in Great Britain for the application of electric transmission of power. If the distribution of electrical energy from a steam-driven central station is to pay at all, then surely South Staffordshire is the place. The various local authorities have been exceedingly perverse in one or two cases, the opposition shown being apparently inversely proportional to the importance of the township, but we cannot help thinking that our friends across the water or the Swiss or Germans, if they had had such a plum in their midst, would have had the alternators turning round before now.

However, we must give Mr. Addenbrooke, and those associated with him, credit for having done their best to pioneer the company through its early stages as quickly as was possible under the circumstances. What is wanted now is some bold financing on the American and German lines, and Mr. Atherton's entrance at this stage is a sign of good omen. It practically means, of course, that the cables will be made at Prescot, and as the cable manufacturer has the greatest stake in a matter of this kind, naturally the promoter will see that the cables are made by the company in which he is interested.

We learn that Messrs. Kincaid, Waller & Manville are appointed consulting engineers, and as this is one of the firms who keep a capable electrical engineering staff, we feel sure that the drawing up of the specifications is in good hands.

Mr. Thomas Parker is, we understand, connected with the new company, but although high tension continuous current has been talked of in connection with the scheme for some time, it is now definitely shelved in favour of multiphase alternating current. Four units of 2,000 KW. and two of 1,000 KW. are to be laid down as a start, and we can only hope that by the time the work is given out to tender, some of our British firms will have got their new shops finished and be in a position to deliver these large units within a reasonable time. It will only be human nature to find that after spending four years in talk, South Staffordshire Bumbledom will look for all the machinery to be delivered and erected in as many months after date of order. Perhaps, however, as some of the directors are manufacturers them-

Digitized by Google

selves, the delivery and penalty clauses will be reasonably drafted, and with a view to placing the work in this country.

We note that the new company has not seen its way to retain Mr. Addenbrooke's services. His cautiousness is perhaps too strongly developed for work which, if it is to be done at all must be tackled boldly, but having once decided to go right ahead on certain definite lines, there were a good many minor points requiring local knowledge, in which the late consulting engineer could have materially assisted the company. The inception of the idea of supplying South Staffordshire with electric power was due to Mr. Addenbrooke, and in the days when some of those now closely interested thought it a Utopian idea, he and Mr. E. Kilburn Scott were laboriously collecting together all the information available and preparing estimates of costs, &c., in such a way that they would appeal to those able to give the necessary financial support.

With good management we are sure that power transmission on a large scale from a steam-driven plant will succeed, and we look forward to the time when we shall be able to describe and illustrate the plant laid down for the wholesale distribution of electrical energy in South Staffordshire.

ELECTRIC TRACTION PROGRESS IN LONDON.

The decision of the London County Council to *experiment* with electric traction renders the present a very fitting opportunity for reviewing the important electric traction projects under construction in the metropolis.

In the course of a few months the City and South London Railway extensions to Moorgate Street and Clapham will be completed, and we hope that the anticipations which have been cherished by the board, of enormous traffic bringing increased dividends to the ordinary stockholders, will be fully realised, for the patience which they have shown year after year with the small interest declared, deserves to be well rewarded. Furthermore, the cordial way in which shareholders of this undertaking meet their directors at half-yearly meetings affords very powerful evidence that they are satisfied that no stone has been left unturned to bring things to a successful issue. The very interesting percentage figures which have been produced by the chairman with clockwork regularity at every meeting, showing the steady decrease in working expenses and the continual increase in receipts per train mile and per passenger, have been an eloquent testimonial to excellent management. The capital outlay upon such lines as the company is now completing is, of course, very heavy, but we are hopeful, when the Bank connection with other railway systems is working and the Islington extension—just commenced—is bringing in the very large receipts which may be reasonably expected, that the small dividend declared for the first half of the present year, viz., 2¼ per cent., will be doubled or trebled.

Turning to other lines, the date for the inauguration of the Central London Railway to Shepherd's Bush seems to be as uncertain as ever. The directors' statement, of course, shows progress in the carrying out of the various works connected with the power station and line work, yet, though things are in a forward state, we shall not for some months be able to announce the opening of the railway for traffic. The undertaking possesses many extremely interesting features, as has been already indicated in our columns, and English electrical engineers will welcome its completion with as much enthusiasm as will the travelling public, to whom it cannot fail to be of great convenience.

The Great Northern and City Railway Company announced last week that contracts for the necessary tunnelling works had been placed and these are making progress. But among the more interesting works of the underground kind is the experimental electrical section of the Metropolitan and Metropolitan District Railways. The managing director does not wish it to be thought that the electrical equipment of the entire lines can be taken in hand immediately, but a couple of months will witness the completion of the experimental line, and that is something to be thankful for. The ultimate result is pretty certain. Let us hope that when the work is taken in hand in earnest, English contractors will carry off the contracts. The two underground electric lines now running—the City and South London, and the Waterloo and City (as yet undescribed by the electrical journals)—have shown what English manufacturers can do in the direction of traction plant. The Metropolitan experimental machinery is of English make, and we do not doubt that the subsequent equipment will be also of home manufacture.

Developments, however, are not confined to underground railways, for the very interesting undertaking of the London United Tramways Company is, so to speak, on the eve of completion. Had there been no London County Council, we should have had many miles of electric tramways running in London years ago, and what that body has not done to oppose the application of electric traction has not been worth the doing. While the London United has been actually constructing its West London lines, the Spring Gardens company has been deliberating as to whether the time had arrived even for *experimenting!* It is a pity that the necessary experimenting was not taken in hand several years ago, when councillors were pleased to fling their diatribes at the overhead trolley system; we might now be reaping the benefit instead of wasting time experimenting with surface contact systems and equipping a trial conduit section. But there, we must be thankful that the Progressive body has at last made progress, though that progress may be very small. The conduit and surface contact system for which the Council's officials are now preparing plans and estimates at a cost of £10,000 will be of great interest to electrical engineers and tramway men both during construction and on completion, but we are afraid that there may be still a feeling in the Council that the equipment of other lines should not be taken in hand until the permanent experimental line has been operating for some months. This may apply to the central thoroughfares, but there seems no earthly reason why the Council should not proceed forthwith with the trolley equipment of the lines on the outskirts. There are rumours of a proposed outlay of a million sterling very shortly. We hope there is truth in the rumour, and that the London Council, which exercises its influence in so autocratic a fashion in labour clauses on behalf of the British workman, will see that English contractors are allowed to carry out the greater share of the work in English electrical factories, thereby benefiting the electrical industry of this country, and, in consequence, the workmen engaged therein.

THE GENERATION OF POWER FOR ELECTRIC TRACTION.

By J. GRAY SCOTT.

(*Continued from page* 80.)

THE regulations issued by the Board of Trade under the provisions of the Tramways Act have already been mentioned, and in conjunction with these, a special panel of the switchboard is usually reserved, and equipped with the necessary instruments.

While these regulations are sometimes considered too stringent, there is no doubt that their requirements may easily be met in any well-constructed tramway system—their observance practically resolving itself into a guarantee of the proper equipment and construction of the line.

The principal trouble, to obviate which these regulations have been framed is, of course, electrolysis; but generally speaking, this has become a thing of the past.

The earlier experiences are too well known to need recapitulation, but the fact that the advantage of thoroughly sound construction assumes *practical* importance is borne out by the following extract from a report by a special commissioner of the *Glasgow Herald*, who visited America a few years ago with the express purpose of investigating the question of electric traction.

As the matter is more or less of direct interest, the author quotes the paragraph *in extenso*:—

Mr. A. Langstaff Johnston has been engineer for the equipment of a number of electric street lines, and his views are important.

He was engineer of the original Richmond (Virginia) electric line, which was the first practicable thing of the country.

It was built in 1887, and equipped by Mr. Frank Sprague.

There were 12 miles of track and 40 cars.

This was the example of the new style of traction which engineers from all over the world came to see.

Mr. Johnston was connected with the equipment, in 1892, of the New Orleans and Carlton road.

In 1891, the gross receipts from horse traction were $175,000. In 1893, when electricity had been installed, the takings rose to $429,000 for the same length of track, viz., 20 miles.

The total expenses, meantime, despite the increase of business, rose only about 25 per cent.

On the question of working expenses, Mr. Johnston is firmly convinced that many companies are still losing a lot of money through defective return circuits.

On one line, 10 miles long, he found, three years ago, that at the fastest speed obtainable, the journey took an hour.

By improving the rail bonding and feeder system, *the time was cut down to 20 minutes, and there was a saving in the coal bill of* $300 *per month*.

The road, it is hardly necessary to say, was a suburban one, but the lesson is the importance of perfect construction, and of employing experienced men.

Presuming this to be an extreme case, it is nevertheless quite apparent that the efficiency of the system must largely depend upon the sound construction and percentage conductivity of the return circuit.

The *raison d'être* of the special panel will be best explained by the following extract from the regulations issued by the Board of Trade:—

2. One of the two conductors used for transmitting energy from the generator to the motor shall be in every case insulated from earth, and is hereinafter referred to as the "line;" the other may be insulated throughout, or may be uninsulated in such parts, and to such extent, as is provided in the following regulations, and is hereinafter referred to as the "return."

3. Where any rails on which cars run, or any conductors laid between or within 3 feet of such rails form any part of a return, such part may be uninsulated.

All other returns, or parts of a return, shall be insulated, unless of such sectional area as will reduce the difference of potential between the ends of the uninsulated portion of the return below the limit laid down in Regulation 7. . . .

5. When any part of a return is uninsulated, it shall be connected with the negative terminal of the generator, and in such case the negative terminal of the generator shall also be directly connected, through the current indicator hereinafter mentioned, to two separate earth connections, which shall be placed not less than 20 yards apart. . . .

The earth connections referred to in this regulation shall be constructed, laid, and maintained so as to secure electrical contact with the general mass of earth, and so that an electromotive force, not exceeding 4 volts, shall suffice to produce a current of at least 2 amperes from one earth connection to the other through the earth, and a test shall be made at least once in every month to ascertain whether this requirement is complied with. . . .

6. When the return is partly or entirely uninsulated, the company shall, in the construction and maintenance of the tramway (A) so separate the uninsulated return from the general mass of earth, and from any pipe in the vicinity; (B) so connect together the several lengths of rails; (C) adopt such means for reducing the difference produced by the current between the potential of the uninsulated return at any one point and the potential of the uninsulated return at any other point; (D) so maintain the efficiency of the earth connections specified in the preceding regulations as to fulfil the following conditions, viz:—

(i.) That the current passing from the earth connections through the indicator to the generator shall not at any time exceed either 2 amperes per mile of single tramway line, or 5 per cent. of the total current output of the station.

(ii.) That if at any time, and at any place, a test be made by connecting a galvanometer or other current indicator to the uninsulated return and to any pipe in the vicinity, it shall always be possible to reverse the direction of any current indicated by interposing a battery of three Leclanché cells connected in series if the direction of the current is from the return to the pipe, or by interposing one Leclanché cell if the direction of the current is from the pipe to the return.

In order to provide a continuous indication that condition (i.) is complied with, the company shall place in a conspicuous position a suitable, properly connected, and correctly marked current indicator, and shall keep it connected during the whole time that the line is charged. . . .

7. When the return is partly or entirely uninsulated, a continuous record shall be kept by the company of the difference of potential during the working of the tramway between the points of the uninsulated return furthest from and nearest to the generating station.

If at any time such difference of potential exceeds the limit of 7 volts, the company shall take immediate steps to reduce it below that limit. . . .

10. The insulation of the line, and of the return when insulated, and of all feeders and other conductors, shall be so maintained that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway.

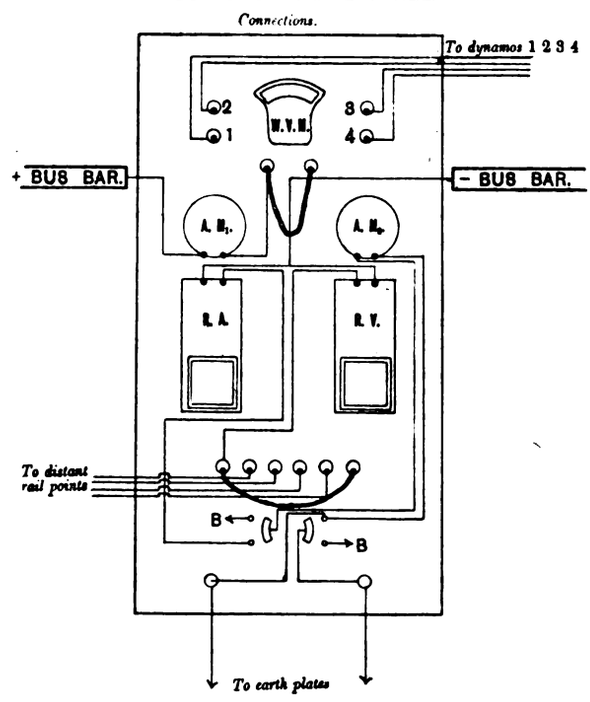
The leakage current shall be ascertained daily before or after the hours of running, when the line is fully charged.

If at any time it should be found that the leakage current exceeds one-half of an ampere per mile of tramway, the leak shall be localised and removed as soon as practicable, and the running of the cars shall be stopped, unless the leak is localised and removed within 24 hours. . . .

11. The insulation resistance of all continuously insulated cables used for lines, for insulated returns, for feeders, or for other purposes, and laid below the surface of the ground, shall not be permitted to fall below the equivalent of 10 megohms for a length of 1 mile.

A test of the insulation resistance of all such cables shall be made at least once in each month.

BOARD OF TRADE PANEL.



The accompanying diagram, though not to scale, shows the general arrangement of the panel, and the connections of the various instruments thereon.

W V M indicates the main station voltmeter, which was temporarily fitted in this position, but, as already mentioned, has now been erected on a swinging bracket at the right hand extremity of the board.

This voltmeter is of the Weston type, and ranges from zero to 600 volts.

Digitized by Google

Immediately below this instrument will be noticed a plug fitting and flexible connected through A M_1 to the + bus bar.

The plug may be inserted in any of the four contacts numbered 1, 2, 3, 4 respectively, and each connected to the + pole of the corresponding generator.

The test is made with the generator at proper voltage but with main switches off, when the reading on the ammeter gives directly the line leakage, and indirectly the insulation resistance of the system.

Precautions should be taken, of course, to have all lamps switched off and trolley poles removed from contact with the line.

The ammeter has two ranges, viz., 0—·05 and 0—·5 respectively.

This test is taken in accordance with Regulation 10.

A M_2 is an ammeter reading 1—10 amperes, and deals with Regulations 5 and 6 (i.).

The former stipulates that the contact of the earth plates with the general mass of earth should be such, that an E.M.F., not exceeding 4 volts, shall suffice to produce a current of at least 2 amperes from one earth connection to the other.

The necessary E.M.F. may be procured by two ordinary Leclanché cells, mounted on a bracket behind the board, and connected (in series) with the two contacts of the two-way switch indicated by B B.

This two-way switch is arranged with a contact block and two contact studs on either side; the contact blocks are always in circuit, and are connected with each of the two adjacent studs in turn.

For the first test (Regulation 5) the position of the switch would be diagonal, as indicated across B B, and presuming B on the left to represent the + pole of the battery, the circuit would be as follows:—

From B (left) to contact block, through A M_2 to left earth plate, thence to right-hand earth plate, and from the other contact block to B (right), which is negative pole of the battery.

To take the other test (Regulation 6, i.), we simply turn the switch to the other diagonal position, bringing into circuit the recording ammeter, R A, and simultaneously putting the earth plates in parallel with each other.

It will be well to follow out the connections:—Starting at the two earth plates, the current passes through A M_2 as before, thence to the left contact block and lower contact stud through the recording ammeter, R A, and so to the — bus bar.

The recording voltmeter, R V, is required by Regulation 7 to give a continuous indication of the drop in volts between various points on the rails and the — bus bar at the station.

The four plug contacts shown are connected to the furthest and nearest points and two intermediate points on the return.

The two recording instruments, which are of Messrs. Elliott Bros. latest pattern, are each of range 0—10.

These give a continuous record of the required tests, and as already pointed out, there is no difficulty in keeping within the prescribed limits in a properly contructed system.

(*To be continued.*)

INSTALLATION ESTIMATES.

(*Concluded from page* 167.)

TABLE II. gives the extra cost if accumulators are used. For installations at home glass boxes are used, but for shipping orders lead-lined teak boxes are necessary. The sulphuric acid must be quite free from chlorine, nitrogen, iron, arsenic or zinc, and it is generally advisable to send it out with the battery rather than trust to local merchants. The price at home is about 3½d. per gallon, but the freight and insurance rates on carboys of acid are very high, and therefore before deciding on whether to use a battery abroad it is necessary to inquire fully into the question of freight, and the kind of handling that the material will get at its destination.

TABLE II.—ADDITIONAL PRICE IF ACCUMULATORS ARE REQUIRED.

		25 lamps.	50 lamps.	75 lamps.	100 lamps.	150 lamps.	200 lamps.	300 lamps.
Cells ...	One set of 58 cells capable of supplying 16 C P 110-volt lamps. Complete with acid, bottom blocks, glass fluid insulators and oil, connecting bolts; and also wood supporting strips and hydrometers.	For 20 lamps for 6 hours.	For 32 lamps for 6 hours.	For 50 lamps for 6 hours.	For 60 lamps for 6 hours.	For 80 lamps for 6 hours.	For 115 lamps for 6 hours.	For 155 lamps for 6 hours.
Dynamo ...	Dynamo to be shunt-wound and increased in size to give 140 volts for charging the battery; also shunt resistance.							
Switchboard	The switchboard to have added to it:—One charge and discharge switch, 12-way; one ammeter switch, 2-way; one automatic cut-out, and one single-pole battery fuse.							
Cable ...	The following additional cable, casing, &c., will also be required:—							
	Insulated cable...	220 yds. 1/8 350 ft. 2 ins. 4 gross.	220 yds. 1/4 350 ft. 2½ ins. 4 gross.	220 yds. 1/8 350 ft. 2½ ins. 4 gross.	220 yds. 1/7 350 ft. 3½ ins. 4 gross.	220 yds. 1/8 350 ft. 3½ ins. 4 gross.	220 yds. 1/8 350 ft. 4 ins. 5 gross.	220 yds. 1/8 350 ft. 4 ins. 5 gross.
	Casing and capping							
	Assorted screws							
	Total extra price ...	£105	£125	£150	£175	£200	£240	£300
	Total weight of above material	38 cwts.	45 cwts.	60 cwts.	75 cwts.	90 cwts.	105 cwts.	140 cwts.

Digitized by Google

Cost of Wiring, &c.

The cost of wiring is a very variable quantity on account of the labour in drilling through walls and making good, &c. The larger the installation the less is the price per point; this is shown in fig. 6 which gives an average price. Fig. 7

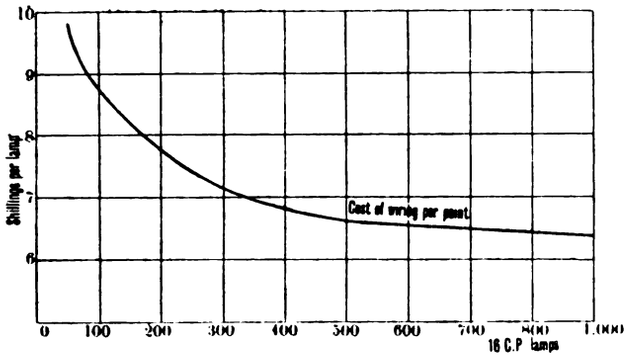


Fig. 6.

gives the total cost, and is taken from the price per lamp in the previous figure, cutting away and making good mouldings, &c., being extra.

Assuming the cost of wiring of an ordinary private house to be unity, then the price for other buildings, &c., compares roughly as follows:—

Private houses	1·00
Textile factories	·75
Printing offices	·80
Engineering and machine works	·90
Breweries	·92
Paper mills	·96
Theatres and music halls	1·00
Hotels and restaurants	1·10
Dye works	1·15

Cutting away and making good decorations, parquet floorings, and other special work should be done by builders and decorators skilled in such work.

With regard to the cables, it is just as well to inquire whether any of the situations in which lamps are to be placed

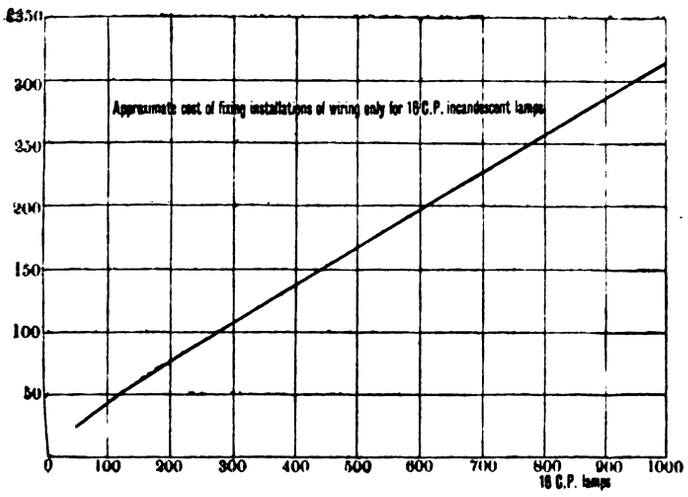

Fig. 7.

are wet. 600-megohm cable is generally employed, but in damp places special precautions must be taken. In estimating for large installations where there are several detached buildings, it is necessary to know beforehand from the proprietor whether he would like the wires carried overhead or underground. In the latter case lead-covered and armoured cable would have to be employed, and it is of course very much more expensive.

The actual cost of cable and casing can, of course, be ascertained by actually measuring along the route to be taken, but most estimates have to be made from rough sketch plans only. About 7s. per lamp will generally cover the wire and 1s. 6d. per lamp the white wood casing, but much depends on whether the lamps are grouped together. Grouping by means of electroliers, &c., reduces the price of the wire and casing and increases the price of the fitting. For ordinary plain electroliers the one will about balance the extra expense of the other. If the casing has to be painted allow 1s. per lamp or point extra. Circuits for heating and cooking appliances should be run independently.

The cost of foundations, mason, and carpenter's work in connection with the generating plant generally costs about 4 per cent. of the total price of the plant.

The cost of erecting the generating plant, including fixing the switchboard and the piping, if quite simple, is about 12 per cent. of the total cost of the plant.

In the above estimates nothing is allowed for spares, these are usually introduced in the form of extras, and may tot up to from 3 per cent. to 5 per cent. on the total contract price.

Working Expenses and Maintenance.

Having dealt with the cost of the installation, there now only remains the question of working expenses and maintenance. Assume that a warehouse has an electric light installation of 200 16-c.p. incandescent lamps of 60 watts each, and that when the number of hours of the lamps burning are all averaged up together they equal, say, three hours per day for 300 days in the year. The total H.P. absorbed at the lamps will be

$$\frac{200 \times 60}{746} = 16 \text{ E.H.P.},$$

or allowing for 2½ per cent. loss in mains, 10 per cent. loss in dynamo, and 5 per cent loss in the belt; the B.H.P. of the engine will equal

$$\frac{16}{\cdot 975 \times \cdot 90 \times \cdot 95} = 19\tfrac{1}{4} \text{ B.H.P.}$$

Multiplying the number of hours by the B.H.P., we get the total number of B.H.P.-hours per annum at 17,400 B.H.P.-hours.

$$3 \times 300 \times 19\tfrac{1}{4} = 17{,}400 \text{ B.H.P.-hours.}$$

If now we multiply this by the pounds of coal per B.H.P.-hour which is consumed by the engine, we shall get the amount of coal consumed in the year, and this at 20s. or whatever the price may be a ton delivered in the stokehole, gives the cost of fuel consumed.

Maintenance expenses are made up of the following items:—

Fuel.—If a steam engine and boiler is used, allow 6½ lbs. of coal per B.H.P.-hour for a simple engine, and 4 lbs. of coal per B.H.P.-hour for a compound engine. In addition to this allow ½ lb. of coal per square foot of heating surface of boiler for as many working days a year as the boiler is running. The price of fuel varies with the locality; cartage and all other charges should be included.

Oil, Waste, Water, and Stores.—Take the total cost of these items at 20 per cent. of the total cost of the fuel. In certain cases the water would not cost anything, and if a filter was used, the oil could be used many times over.

Attendance.—For an installation up to 300 lamps, one man at, say, 35s. per week would be sufficient in this country. From 300 to 900 lamps, allow for one man at 40s., and an assistant at 20s.

Renewals.—It is usual to calculate that incandescent lamps require renewal after about 800 hours. Of course, some will give a good light for a longer period, but these are balanced by breakages, &c. The price of a 16 c.p. 110-volt lamp can be now taken at 9d. The lamp tops can be afterwards sold for the platinum.

Repairs.—This item should be taken at 2½ per cent. on the total capital cost of the installation.

Depreciation.—Taken at 5 per cent. on capital cost.

Interest.—Taken at 5 per cent. on capital cost.

Notes on Arc Lamps.

For outdoor illumination about 1 c.p. per 10 square feet. The usual method is to place the arcs a certain number of yards apart, say 50, and 22 feet high. For indoor lighting allow 2½ c.p. per 10 square feet, the inverted arc is the best to use for indoor work.

The usual sizes for arc lamps are 750 c.p., 1,000 c.p.,

Digitized by Google

1,500 c.p. and 2,000 c.p. The first two can be used for the illumination of halls, stores, lofty warehouses and yards, whilst the last two are for the lighting of streets, railway yards, carriage drives, &c.

The price of one 1,000-c.p. arc lamp installed complete at, say, 100 yards from the dynamo would be about £7; a lamp-post would cost extra.

If of wood	15s.
Ordinary iron post	£3
Lattice poles 50 feet as used in railway yards	£18
Wall bracket	£2

The cost of carbons for a 1,000 c.p. lamp is ¼d. per lamp hour burnt.

In calculating the power required for ordinary open arc lamps working on a 110-volt circuit, it is necessary to note that when there is an odd number the odd lamp will require as much energy as two lamps, the extra amount of power being absorbed in the resistance in series with it. With enclosed long burning lamps which must of necessity be arranged singly across the 110-volt wires this does not apply.

RETURN FEEDERS FOR ELECTRIC RAILWAYS.

(*Continued from page* 181.)

IV.—Graphic Determination of the Cross-Sections.

If only one end cable is used, the expression for the volume of copper, as we have seen above is:—

$$\Sigma\,(\text{vol.}) = \frac{C\,L^2}{3\,K\,\Delta} + \frac{C\,L^2}{6\,K\,\Delta} = \frac{C\,L}{2\,K\,\Delta}\,L = \Sigma\,(s)\,L.$$

When there are an infinite number of cables, the second member of the expression vanishes, and

$$\Sigma\,(\text{vol.}) = \frac{C\,L^2}{3\,K\,\Delta} = \frac{2}{3}\,\frac{C\,L}{2\,K\,\Delta} = \frac{2}{3}\,\Sigma\,(s)\,L.$$

The first volume can, therefore, be represented by the area of a rectangle whose sides are $\Sigma\,(s)$ and L; and the second by a parabola enclosed in the rectangle. The volume of a finite number of cables lies between these two areas.

This representation of the two limiting volumes furnishes us with an exceedingly simple graphic method of determining the section of each cable, whatever number of cables are used.

The process is as follows: the $\Sigma\,(s)$ is determined by the formula, and with this value, and L the length of the line, a rectangle is drawn (fig. 3). The parabola is drawn with the formula $y^2 = 2\frac{L\,K\,\Delta}{C}\,x$, which gives the final values of x and y as $\Sigma\,(s)$ and L respectively. Upon the length L_1 points are marked where the intermediate cables are connected. Let two be connected at 6 and 12 kilometres. From the point 6 a parallel is drawn to the axis X, cutting the line O R in the point N. If $N_1\,P_1$ is made equal to $P_1\,N_1$ then N N_1 represents the section of the first cable. Draw now, through the point N_1 a line N_1 M parallel to the line A E, and draw from the 12 km. point a line parallel to the axis X to cut the line N_1 M in M. Choose the point M_1 so that $M_1\,P_2$ is equal to M P_2; then M M_1 will represent the cross-section of the second cable. The remaining part of the line, S E, gives the cross-section of the end cable.

Before giving the proof of the correctness of this construction we shall show, by an example, that the cross-sections obtained agree with those obtained by the general formula.

If we designate the co-ordinates of the points of the parabola, $P_1\,P_2$ E by $x_1\,x_2\,x_3$ and $y_1\,y_2\,y_3$, then according to the construction

$$s_1 = 2\,x_1,$$
$$s_2 = 2\,(x_2 - s_1) = 2\,(x_2 - 2\,x_1),$$
$$s_3 = x_3 - (s_2 + s_1) = x_3 - 2\,x_2 + 2\,x_1.$$

The value of the ordinates, y, corresponding to the values of the abscissæ $x_1\,x_2\,x_3$ are $\frac{L}{3}$, $\frac{2}{3}$ L and L_1, and from the equation to the parabola we deduce

$$x_1 = \frac{1}{9}\,\frac{C\,L}{2\,K\,\Delta} \text{ and } s_1 = \frac{2}{9}\,\frac{C\,L}{2\,K\,\Delta},$$
$$x_2 = \frac{4}{9}\,\frac{C\,L}{2\,K\,\Delta} \qquad s_2 = \frac{4}{9}\,\frac{C\,L}{2\,K\,\Delta},$$
$$x_3 = \frac{C\,L}{2\,K\,\Delta} \qquad s_3 = \frac{3}{9}\,\frac{C\,L}{2\,K\,\Delta}.$$

From this, volumes come out

$$v_1 = \frac{2}{9}\,\frac{C\,L}{2\,K\,\Delta}\cdot\frac{L}{3},$$
$$v_2 = \frac{4}{9}\,\frac{C\,L}{2\,K\,\Delta}\,\frac{2\,L}{3},$$
$$v_3 = \frac{3}{9}\,\frac{C\,L}{2\,K\,\Delta}\,L;$$

adding these

$$\Sigma\,(v) = \frac{C\,L^2}{2\,K\,\Delta}\left\{\frac{2}{27} + \frac{8}{27} + \frac{9}{27}\right\} = \frac{C\,L^2}{2\,K\,\Delta}\cdot\frac{19}{27}.$$

This value can be split up into

$$\frac{C\,L^2}{3\,K\,\Delta} + \frac{C\,L^2}{6\cdot3^2\,.\,K\,\Delta},$$

or in terms of the general formula, when $m = 2$,

$$\Sigma\,(v) = \frac{C\,L^2}{3\,K\,\Delta} + \frac{C\,L^2}{6\,(2+1)^2\,K\,\Delta}.$$

We see, from this, the values for the volume of the copper obtained from the diagram agree with those obtained from the general formula.

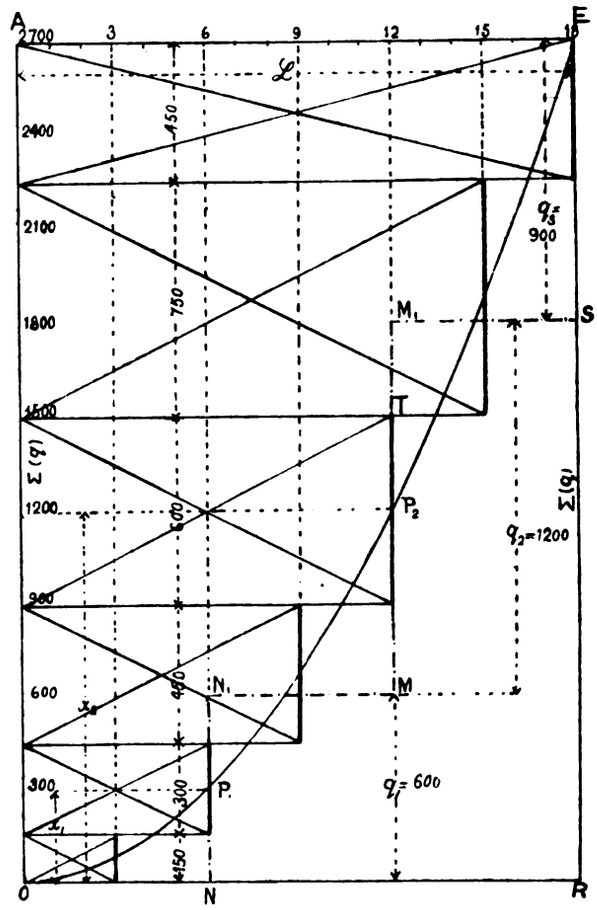

Fig. 3.

It now remains to show that the section obtained by the diagram for each separate cable is correct. Of course, with assumption of constant potential drop and current that has been made, the cross-sections are proportional to the lengths of the cables, so that if l, 2 l, 3 l . . . . are the lengths of the cables, $s_2 = 2\,s_1$, $s_3 = 3\,s_1$ . . . . $s_r = r\,s_1$. Consider now the cross-section of the cable, of which the length is $r\,l$. As is evident from fig. 3, half the sum of the cross-sections of the rth and $(r-1)$th cables, is equal to the difference of the abscissæ x_r and x_{r-1}, *i.e.*,

$$\tfrac{1}{2}\,(s_r + s_{r-1}) = x_r - x_{r-1}.$$

Digitized by Google

Since the cross-sections are proportional to the lengths,

$$s_{r-1} = s_r \frac{r-1}{r},$$

therefore $$\tfrac{1}{2}\left\{ s_r + s_r \frac{r-1}{r} \right\} = x_r - x_{r-1},$$

or $$\tfrac{1}{2} s_r \frac{2r-1}{r} = x_r - x_{r-1}.$$

Now according to the equation to the parabola,

$$x = \frac{y^2 C}{2 L K \Delta}.$$

Since for x_r, $$y = \frac{L}{m+1} r,$$

and for x_{r-1}, $$y = \frac{L}{m+1}(r-1),$$

$$x_r = \frac{L^2}{(m+1)^2} r^2 \times \frac{C}{2 L K \Delta}$$

and $$x_{r-1} = \frac{L}{(m+1)^2}(r-1)^2 \times \frac{C}{2 L K \Delta}.$$

These values, substituted in the above equation, give

$$\tfrac{1}{2} s_r \frac{2r-1}{r} = \frac{L C}{(m+1)^2 2 K \Delta}\{r^2 - (r-1)^2\},$$

or $$s_r \frac{2r-1}{r} = \frac{L C}{(m+1)^2 K \Delta}(2r-1),$$

therefore, $$s_r = \frac{C L}{(m+1)^2 K \Delta} r.$$

This expression is the desired cross-section. The current in the end cable is only half that in an intermediate cable, therefore the line representing its cross-section stops at the parabola (E, fig. 3).

In fig. 3 the construction for five intermediate cables and one end cable is also shown. The cross-sections obtained are 150, 300, 450, 600, 750 and 450 mm². The area of the crossed rectangles represent the copper volume of each cable.

It is evident from the graphic construction that it makes no difference to the total cross-section of the cables, where the cables are connected to the line. The cross-section of the end cable is (see above) $s_e = \frac{C L}{2 \Delta K (m+1)}$. It depends, with the given conditions of working only on the value of $(m+1)$, that is upon the current $\frac{C}{m+1}$; it makes no difference whether the sum of the other currents is taken by several or by one intermediate cable, if the connection points of the latter are chosen so as not to change the current in the end cable. If there are m intermediate cables, the last cable connects to the line at a point $\frac{L}{m+1}$ from the end cable. Now, the expression for the cross-section of the end cable can be written

$$s_e = \frac{C L}{2 \Delta K (m+1)} = \frac{\Sigma(s)}{m+1}.$$

Therefore the cross-section of the end cable is proportional to its distance from the last intermediate cable.

If, for example, one intermediate cable is connected at 12 km., the length, $\Sigma(s) = 2{,}700$ mm², is to be divided in the ratio of 6 : 12, and the shorter length $2{,}700 \times \frac{6}{18} = 900$ is the cross-section of the end cable. The remaining 1,800 mm² of cross-section falls to the share of the single intermediate cable at 12 km., or to any given number of intermediate cables connected at equal intervals, whose sections may be determined by the graphic construction as already described. If, for example, cables were connected at 4 and 8 km., the section for these comes out 266 and 534 mm². Since 900 mm² fall to the share of the end cable, 1,000 mm² is left for the 12 km. cable as the construction shows.

(To be continued.)

THE REPORT OF THE PACIFIC CABLE COMMITTEE.

(Continued from page 184.)

Sir W. H. Preece gives the average number of letters per word in trans-Atlantic traffic as 7·3; this figure was arrived at by actually counting the words in the body of every message for the Anglo-American Company which passed through several postal telegraph offices, for two hours during six days, and should therefore be a very useful figure; making allowance for spacing, the word is taken for sending purposes as consisting of eight letters, and the non-paying words are given as about 48 per cent., a percentage of loss which it appears would increase as the clerks grew tired. Mr. Lucas says that "70 letters per minute would give you on the section from Vancouver to Fanning Island something like four or five paying words per minute, not more." Assuming these to be words of eight letters, this means a "dead" traffic of about 50 per cent. Dr. Muirhead, after premising that he is calculating on the basis of the experience of the Eastern companies, according to whom he says "as much time is given to preamble, &c., as to messages," goes on as follows: "on the assumptions, (1) that only average operators are employed; (2) that the average length of code words is nine letters; (3) that half the time of transmission is occupied with preambles, calls, services, and other unpaid matter; and (4) that duplex automatic curb transmission is adopted, a cable 3,600 knots in length of a core weighing 500 lbs. copper and 320 lbs. gutta-percha per knot would earn eight paying words per minute. The same length of 552 copper and 368 gutta-percha core would earn nine paying words per minute." From the above we gather that as the core 500/320 will, according to a previous answer given by Dr. Muirhead, carry 140 letters per minute under conditions similar to those explained above, the non-paying words amount to about 50 per cent. of the traffic. It must be borne in mind here that Dr. Muirhead is not basing this figure on his own observations.

There is a considerable discrepancy between the figures given by the two groups of witnesses as representing the proportion of non-paying traffic; some of these are not expressly stated, and we have had to deduce them from various portions of the evidence, but those representing the Anglo-American Telegraph Company, the Commercial Company, the South American Cable Company, and the Indo-European Government Telegraph cables, all agree in giving the proportion of "dead" traffic transmitted as being between 10 and 16* per cent. of the total; whereas the Eastern Telegraph Company make this about 75 per cent., and the Post Office officials give about 48 per cent. at the lowest valuation. It is obvious that as far as estimating the "profit-earning" capacity of a cable is concerned, it is important that the line should be worked under the most economical system of management, and in the absence of fuller explanations we prefer to accept the figures given by the group of companies above mentioned; always bearing in mind that in the case of the Pacific cable, the messages in transit between England and Australia, which will undoubtedly form the bulk of the traffic, and which will pass through Canada, there will not be that necessity for the lengthy indications which, as Mr. Lamb points out, are used for purposes of International account, &c., on lines which pass through various foreign countries. Mr. Lamb expresses an opinion that every one of such indications would have to be sent on a Pacific cable, because the Australian Colonies are parties to the International Convention, but in question 2,255, this witness says, in reference to the creation of competition in charges between existing routes, "where States are concerned, the intention of the International Telegraph Convention is that one set of States shall not disregard the interests of another. In this case I think it might be shown that the Mother Country and the Australian Colonies—who are all parties to the International Convention—would be disregarding the interests

* In their report the Committee state that the non-paying traffic is given as 15 per cent. in the case of Mr. Carson, and 17 per cent. in the cases of Messrs. R. Kaye Gray and Finch, but an examination of the evidence will show that the figures which we have used more accurately represent the evidence given.

Digitized by Google

of India, which is also a separate member of the International Union."

In Mr. Ffinch's evidence we find the following in a letter from the Secretary of State for India:—"I am to enclose, for the information of Mr. Chamberlain, a statement showing the extent to which the Indian revenues are concerned in the existing lines; but, having regard to the considerations represented in your letter, Lord George Hamilton is not disposed to make this a ground of preliminary objection against any scheme for an alternative route to which Her Majesty's Government may attach commercial or strategic importance." This does away with the fear of any objection from India as an adherent to the Convention.

As regards the amount of traffic which would probably be directed over the Pacific cable, Sir Sandford Fleming has assumed this amount to be equal to half the existing traffic between Europe and Australasia; and this seems a very fair assumption, as, given equal rates over the Indian Ocean and the Pacific Ocean cables, and supposing both of these to be equally efficient, the Pacific cable has the advantage of landing in the vicinity of the business centres of Australia, the joint population of New Zealand, New South Wales, Queensland, and Victoria being 3,700,000, as against the 530,000 in Western Australia and South Australia, where the existing cables land, at Roebuck Bay and Port Darwin respectively. These latter landing places are connected to the first-named group of colonies by very long landlines, which do not give a satisfactory service. The land distance from the Port Darwin landing to Sydney is about 3,000 miles, while the length of landline from Roebuck Bay to Sydney is about 3,800 miles. For the above reasons, and also because the majority of the unrouted traffic will probably be sent *viâ* the Pacific, it appears to us that Sir Sandford Fleming has not been over sanguine in claiming 50 per cent. as the amount of traffic which will probably accrue to the Pacific cable. The total number of words transmitted between Australia and Europe in 1896 is given as 2,326,984. The representatives of the Eastern Extension Company assume that their line would retain all the West Australia and South Australia traffic, also one-half of that of Victoria and Tasmania, and one-quarter of the messages to and from New Zealand and New South Wales. We must say we cannot see on what foundation this reasoning is based; such a division seems an extremely hopeful one on the part of the company. Sir W. H. Preece goes into an interesting calculation, by which he shows that assuming a cable which can only transmit three (paying) words per minute, and which is only worked for 10 hours per day, owing to the clerks being "tired," and only 300 working days in the year, then such a cable will not carry more than 540,000 words in 12 months. As the particular cable referred to was calculated by Dr. Muirhead and given when working duplex 20 eight-letter words per minute, and as the evidence shows that 25 per cent. is a very liberal deduction to make for non-paying traffic, we get 15 words per minute instead of three, and by the simple process of doubling the 10 hours (and Sir W. H. Preece gives no good reason why this should not be done), we get 20 out of the 24; this, at the narrow estimate of 300 days to the year, gives us 5,400,000 words per annum. Sir W. H. Preece seeks to reduce the possible working day of this cable to 10 hours by such reasoning as the following, in reply to Lord Selborne:—

1,370. I will assume your three words per minute, but I want to go very closely into this question of 10 hours. Ten hours, you tell us, is by practical experience what these telegraph cables work at?—It was my practical experience of the work of telegraphs generally. I want particularly to consider this part of the business as absolute estimate, and I want to have it confirmed or upset.

1,371. All business that comes to the telegraphs over which you have control can be cleared in 10 hours' working?—Yes, certainly. That is much more than our telegraph experience in England. It will be more like four or five hours.

1,372. Then supposing the work to be double, would it not be merely a question of staff to work 20 hours a day?—It would be a question of business more than staff, because you cannot attract it.

1,373. I said suppose the business to be doubled, could not that business be worked off on the same line in 20 hours by merely increasing the staff?—No, because I have assumed that the high pressure of course with this work cannot be maintained during the 24 hours, even with a fresh staff of clerks.

1,374. Why not?—For the reason that I gave, that clerks tire, and you cannot maintain high pressure for a long period.

Mr. Murray.

1,375. And you cannot get the work at the right time?—That is another element. That is where the work does not come; it only comes in driblets, as a matter of fact.

Chairman.

1,376. But supposing one office, we will say going to America, suppose on some great occasion an immense amount of work comes in during the day, that would be worked off during the night?—Of course.

1,377. And customers do not complain, as a general rule, because their telegrams may be delayed an hour or two?—No.

1,378. Is it your experience that they do?—I beg your pardon.

1,379. Is it your experience that if a telegram is handed in for Australia, we will say to-day, is the public fairly satisfied if they get an answer within a certain number of hours?—I think so. I think very well satisfied if they get an answer in 24 hours.

1,380. In 24 hours?—Yes.

1,381. And therefore, at a stress, arrears could be worked off during the night?—Yes.

1,382. That being so, I do not understand why you are of opinion that we are obliged to reckon the working of any cable at 10 hours as the only time at our disposal?—Because these calculations are based on the assumption that our maximum speed is obtained under great pressure, and that this great pressure cannot be maintained for reasons that I have given. You must not take a maximum speed as your working speed, but you must take a mean speed. That has varied very much by the companies I gave you.

1,383. But you cannot be accused of taking a maximum speed. You have, by a process which has interested the Committee very much, reduced the working speed down to three words a minute?—Yes.

1,384. That you do not consider a maximum speed?—No; I call that the ordinary working speed.

1,385. The ordinary working speed. Then why cannot that speed be maintained for as many hours over the line as you can find staff to work it?—So you could if you had the work.

CORRESPONDENCE.

The Direct Reading Ohmmeter.

I note in your issue of July 14th, that Mr. N. C. Woodfin, of Patterson, Cooper & Co., recites his experience with the direct reading ohmmeter.

With reference to what he says concerning the use of the instrument in a noisy place, I would say that I have been able to secure quite accurate results by noting the places on either side of the silence point where the noise begins and bisecting the distance between them. The noisier the place the wider this gap will be, but with care and a little practice I have been able to secure almost as accurate results in moderately noisy places as in silent ones. I have also found it necessary to keep the dry batteries in the bridge in good order, and when the click on the instrument becomes faint it is best to renew the batteries, which can be done at a cost not exceeding 3s. With these precautions well in mind I have had no difficulty in attaining the claims of the makers of the instrument.

It is perhaps well to state that in the measurement of very high and very low resistances the accuracies of ½ per cent. are exceedingly difficult if not impossible to attain with an instrument of the Wheatstone bridge type. With high resistances, such as insulation resistances and the like, I find that the insulation resistance seems to be proportional to the very variable and erratic function of the temperature and of the voltage applied, and the possibilities of measuring such an elusive resistance with anything like accuracy are very remote. This, however, is not the fault of the instrument, for it is doubtless theoretically correct at those points. The scale is laid out according to a mathematical law, and there is no reason why this should not be so.

With reference to the measurement of low resistances, that is to say, exceedingly low resistance such as armature coils or armature resistances, I would say that I find that the difficulty of making connections of negligible resistance, limits the accuracy of the instrument. In measuring the resistance of armatures it is difficult to obtain connections to the resistance to be measured of lower resistance than the armature itself. This, again, is no fault of the instrument, but rather due to the fact that the instrument is out of its class. I have always obtained my best results in measuring very high resistances with the aid of a voltmeter and a substantial voltage of 110 to 500 volts, and the low resistances I find are best measured by a fall of potential method. For the measurement of intermediate resistance I have found the ohmmeter exceedingly accurate and satisfactory.

Digitized by Google

With regard to portability I would say that I have a leather carrying case with a strap, which seems to answer every requirement, and also prevents the box from being marred.

Geo. T. Hanchett.

The Pacific Cable.

It has been brought to my knowledge that you have been defending me against the chairman of the Eastern Telegraph Company in respect of strictures by him on an opinion incidentally expressed by me as to the vulnerability of our great telegraph routes in time of war. I did not answer these remarks because the matter was, as I say, only an incidental one in my speech on the deputation to the Chancellor of the Exchequer, and I was, in fact, only engaged in replying to some observations in the other sense which had been previously made by Lord Tweeddale. The subject is one which will sooner or later come up for debate in Parliament, and, if necessary, I shall be able there to express my views. My main statement was that all our communications with the East, and, indeed, with our leading strategical points generally, are within the control of possible enemies, in Russia, Turkey, or Persia, or else touch at Lisbon. In many cases they both touch at Lisbon, and also pass through one of the three countries named. Lord Tweeddale appeared, in his reply, to throw doubt upon the accuracy of this statement, and to suggest that he knew of some direct British route to Gibraltar at least. But no such route is marked on the latest cable maps.

Charles W. Dilke.

Electrolytic Extraction of Zinc.

In examining the papers which have recently reached me, I find two numbers of the ELECTRICAL REVIEW, the one dated July 7th, and the other July 14th last; at the pages 36 and 37 of the first number and at the page 43 of the second, I noticed two articles concerning the electrolytic extraction of zinc (by the Hoepfner and the Cowper-Coles processes).

Both methods seem to be characterised by the application of the rotary cathode, claimed by me in my English patent dated April 1st, 1892, No. 14,892. Everybody may look into the same patent at the Patent Office. The United States patent which has been granted to me for the same object on September 24th, 1892, under No. 446,775, may also be looked at.

I wished to draw the attention of the readers of the ELECTRICAL REVIEW to the fact that up to the present date no one has been able to oppose any anteriority whatever to my rotary cathodes, not even the patentamt of Berlin.

As you publish the descriptions of processes in which rotary cathodes are used, I rely upon your impartiality and your courtesy to insert the present letter.

D. Tommasi.

Paris, *August 1st*, 1893.

Re The Patent Renewable Glow Lamp.

Anent your remarks on above in last week's issue of your enterprising journal, will you permit an old reader, and a friend of the patentees, and one cognisant of the incomparable advantages of which the above lamp is alone capable, to clear the ground of certain misapprehensions in this relation? First let me say that, had I space and your permission, to give in detail the unique capacity of this lamp to prolong its utility, at such a small outlay of material, time, labour and money, and to explain *how* through the continuous interchangeability of its filaments the thorough utilisation of *all* its material is effected to the utmost extent, the commercial value, and complete public service claimed for this innovation by those of the highest repute and honour as practical experts, who have submitted it to the most crucial tests, would be so manifest that, even your hypercritical correspondent, "Experientia Docet," would admit the justice of the claim that this lamp will not only be the salvation of the enclosed globe, but supplies the long felt public want among consumers of the current, by revolutionising the present system of lamp replacements, and doing away with the practice of having *new lamps, and paying full prices for same.*

And so far from efficiency being sacrificed for cheapness, it will be found, by comparison, that it is the highest ever recorded so soon as the lamp is on the market.

Surely it must be a great commercial achievement in any industry *to reduce maximum waste of material and labour.*

As instanced in the glow lamp industry at present, incomputable and broadcast waste of glow lamps takes place the moment the lamps at present in use reach the end of their first and only life.

True, many have tried to solve the problem of interchangeability of filaments, even Westinghouse with his glass stopper, &c. How impracticable these devices were doubtless you are aware, sir, but none hit upon the simple design of a tubular neck and expeditious method of exchanging filaments devised by C. Howard.

Depend upon it, sir, if the advantages claimed were not genuine, and had not been actually demonstrated, neither Sir W. H. Preece's nor Major Cardew's name would have been on the front page of the prospectus to bear testimony to the same. Neither would Mr. Jacob Atherton, of the British Insulated Wire Company (a most successful company), have been identified with it unless it was the inimitable lamp the inventor asserts it to be. The economy claimed will, on comparison, be found to be actual and enduring, and be assured that it has come to stay, despite "Experientia Docet," whose friends will find shortly that their large stock of lamps, &c., &c., are obsolete and unsaleable. Without attempting to answer his assertions, let me say that all his objections have no relation, or bearing, to the above lamp, and prove conclusively "how little" he knows of the invention.

In conclusion, let me add that (1) the company only claim to renew their own lamps, it's impossible to renew any other. (2) The filaments are of that peculiar kind that the bulbs are free from deposited carbon. (3) The glass, too, is unique, and manner of opening and fusing so practicable that breakages will be very rare. (4) The detachable socket has withstood the most severe tests, and is a perfect success, and will admit of being used perpetually. (5) In all other lamp factories there is a certain loss of between 25 and 30 per cent. on lamps made, through some non-glowing defect, broken filaments, &c., in the manufacture of this lamp *such loss will be unknown*, as the least, or most serious, defect can be at once rectified by opening at neck where renewal of filaments takes place. That the economising and prolonging utility of this lamp is without parallel in this electrical age, goes without saying, and consumers will ere long have the opportunity of verifying.

I could add to what I've said, but for fear of incurring your displeasure, Mr. Editor. Thanking you in anticipation of your inserting this, and apologising for its length, I remain faithfully yours,

Charles Clifford.

[This letter leaves us little the wiser, but so that we may be further enlightened our "space and permission" are both at the writer's disposal.—EDS. ELEC. REV.]

Gas Engines v. Electro-Motors.

Why, in your issue of 28th ult., do you discredit the 20 cubic feet per B.H.P. per hour gas consumption of the Stockport gas engine, while giving prominence (and credence) to the 16·78 cubic feet per B.H.P. per hour gas consumption of the Westinghouse engine?

Of course, your notice does not state the consumption of the Westinghouse engine in terms of the B.H.P., but that is what 1,000 cubic feet giving 40 KW.-hours means at 90 per cent. dynamo efficiency.

Judging from my own experience of gas engines, neither result is in any way extraordinary. On one of Messrs. Crossley Bros'. new designs I obtained a B.H.P. for 13·5 cubic feet of 700 B.T.U. gas per hour—a result which, at the time, I considered a record, and which, I believe, can be repeated at any time. As this gives a thermal efficiency of 27·1 per cent., you will appreciate my belief in the record; but, unfortunately, I found in the *Railroad Gazette* particulars of a test made on a 6 × 11 two-cylinder "Pittsburg" (*i.e.*, Westinghouse) engine that eclipses my result completely. This engine gave 9·1 B.H.P. for a consumption of 165 cubic feet of 434·3 B.T.U. gas per hour. The consumption per B.H.P. is thus 18·13 cubic feet per hour, but owing to the low calorific value of the gas, this gives the extraordinary thermal efficiency of 32·3 per cent. From this it must be considered that the Westinghouse

D

Digitized by Google

engine is 16·6 per cent. more efficient than the Crossley engine. I will not attempt to account for this extraordinary superiority of the Westinghouse engine, but I may point out that it is in no way due to the fact that the Westinghouse engine governs on a reduced compression charge (*i.e.*, by throttling), while the Crossley engine governs by cutting out charges, and maintains a constant compression, for both engines were then working at full load igniting every time. In conclusion, I would remark that the Westinghouse engine is "not" the only engine that governs by throttling its charges. There are large numbers of engines working in this country with stepped air and gas cams under control of the governor, which operate exactly in the same way as the Westinghouse engine; but these, on the whole, have not been found to compare at all favourably with engines governed on the "hit-and-miss" principle. The superior economy of the engines governed on the latter principle is such as to admit of the slight sacrifice of mechanical efficiency due to the use of the heavier fly-wheels necessary to give equal steadiness of running in both types, and still be superior in thermal efficiency.

Asbestos.—The Admiralty contract for asbestos goods for the ensuing 12 months has again been awarded to the United Asbestos Company, Limited. This is the 14th year in which the company have been awarded important contracts by the Lords of the Admiralty.

Bankruptcy Proceedings.—The public examination of Alec Gavin Inrig, electrical engineer, 44 and 46, White Post Lane, Victoria Park, trading as the Globe Electrical Company, was held last week at the London Bankruptcy Court. The debtor has filed accounts showing liabilities £4,514 3s. 5d., against assets £330. In the course of his evidence the debtor stated that he came over from Antwerp in September, 1895, with a capital of £1,000, and started the above business. Four months later he was joined by a Mr. Chester, and they converted the business into a company styled Inrig and Chester, Limited, with a capital of £2,000. As vendor witness received £500 in fully paid shares, and he acted as joint managing director at a salary of £200 per annum, until the company went into liquidation at the end of 1896. The petitioning creditors next purchased the concern from the Official Receiver, and agreed to sell it to witness under a hiring agreement, but nothing further was done, and he managed it on their behalf at a salary until last November, when they refused to make any further advances. He subsequently carried on the business upon his own account until they (the petitioning creditors) brought him to the court early in June. To the action of those creditors, witness entirely attributed his failure. The examination was ordered to be concluded.

The examination in bankruptcy of John Lumsden Sloan, as sole partner of the firm of Wilks, Sloan & Co., electrical and consulting engineers, 112, Bath Street, took place in Glasgow on 7th inst., before Sheriff Balfour. In reply to Mr. George S. Robb, for creditors, bankrupt stated that he was interested in the reversion of the estate of Sir James Lumsden. In January a loan of £300 was obtained from a firm of money-lenders in Edinburgh, and he and Mr. Wilks and the cautioner signed a bill for £450. At this time he was drawing nothing from the business. The bulk of the loan was handed to Mr. Wilks, who was being pressed, to cover his private liabilities, and between £10 and £20 went into the business. A loan of £300, entirely for Mr. Wilks' benefit, was got from bankrupt's brother, who was to have a percentage on the money, and to have the option of becoming a partner at any time within three years. Before this Mr. Wilks had overdrawn his interest in the firm to a considerable extent, and any sum that went into the firm was to repay what he had overdrawn. Bankrupt put £250 into the business, and his loans to the firm and Mr. Wilks amounted to £750. The examination was adjourned.

Catalogues, Lists, &c.—From the Prentiss Clock Improvement Company, of New York City, we have received a pamphlet describing their improvements in long-running clocks and automatic perpetual calendars, also their synchronising and electrical controlling devices.

Messrs. Nalder, Brothers & Co., of Westminster, have issued a new edition of their catalogue of scientific instruments, in which they give capital illustrations, and neatly arranged data of their various instruments for electrical testing, also for engineering, mathematical, optical and other purposes. The opening page has a reproduction from a Röntgen photograph of the N.C.S. four-coil Kelvin galvanometer, showing the internal arrangements and connections. The class of apparatus made by Nalders is so well known that it is quite unnecessary to detail here the numerous instruments which find a place in this catalogue, which is a credit to compiler, illustrator and printer.

A new issue of the Concentric Wiring catalogue of Messrs. J. D. F. Andrews & Co., Limited, is to hand. It shows many new appliances and improvements.

A second edition of the Brush Electrical Engineering Company's Universal Engine Book has lately been brought out, giving some excellent sectional and general illustrations of the engine and parts, and describing the chief features.

From the Taper-Sleeve Pulley Works, of Erie, Pennsylvania, we have received an illustrated list of their solid-web, iron-centre, hardwood dynamo, motor and generator pulleys, with copies of testimonials, code, &c.

The Western Telephone Construction Company, of Chicago, sends a copy of its catalogue of switchboards and apparatus required in connection with telephone exchange systems. Views are given of the various departments at the works, also of exchanges fitted with the company's manufactures, and there are also a number of illustrations of the apparatus described.

An incandescent lamp list, printed in English, French, and German, comes to hand from Mr. Paul Goldschmidt, of Featherstone Buildings, W.C. It contains particulars of the manufactures of Messrs. P. & M. Herre, of Berlin, who are specialists in small and fancy lamps. We understand that the factory equipment at Berlin is quite up to date, and includes the newest and best air pumps which are worked by motor. The list before us contains details regarding a large variety of fancy lamps of all designs, shapes, and sizes; also holders, switches, brackets, Geissler tubes, Crookes tubes, Ruhmkorff coils, &c.

The Electrical Company, Limited, has issued a new price list of carbons for "Luna" arc lamps.

Change of Address.—Mr. E. O. Sachs has moved his general and private offices from No. 11 to No. 3, Waterloo Place, Pall Mall, S.W.

Copper.—The *Financial News* says that some of the strength has departed from the statistical position of copper; for Messrs. Merton's figures show that the visible stock at the end of July had risen to 33,019 tons, compared with 28,515 tons a fortnight earlier, and 29,009 tons a month ago. Supplies were larger in July than for several months, and consumption has been checked—whether temporarily or not it would be difficult to say; for the jump from deliveries of 16,074 tons in May to 19,077 tons in June and the fall to 16,327 tons in July show an irregularity that puts generalisation at a discount. The supplies were 20,342 tons against 17,925 tons in June, and that in spite of a reduction of 4,100 tons in the arrivals from North America. "Other countries," which represent a variable quantity in the supplies, and cover all the copper-producing countries save North America, the Peninsula, Australia, and Chili, sent 6,767 tons in July, against 2,126 tons in June, and shipments from Chili were nearly 2,000 tons greater.

Digitized by Google

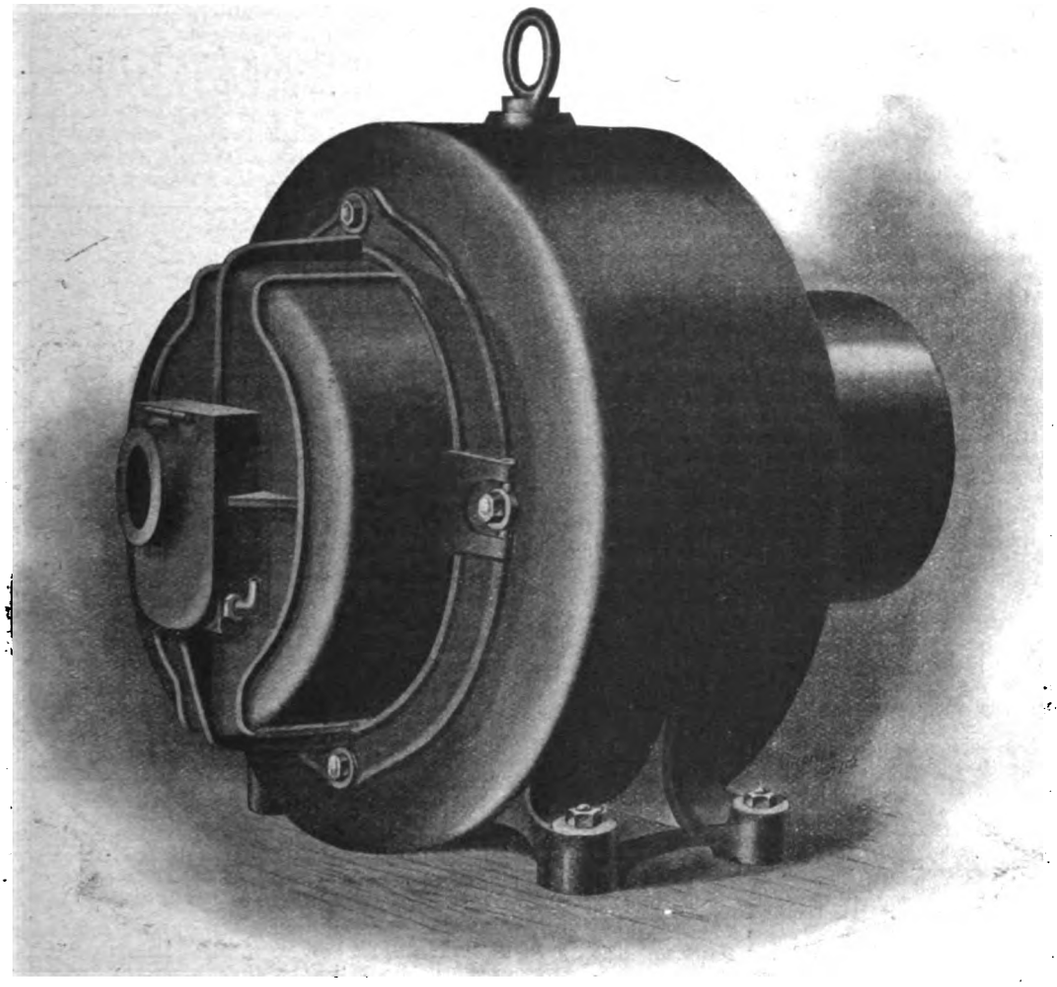
Coal Cutting.—Mr. E. W. Parker, of the United States Geological Survey, gives the following data with regard to the progress of mechanical coal cutters in America:—

Year.	No. of machines at work.	Tonnage mined by machinery.	Average prices at mines.
1891	545	6,211,730	4s. 10d.
1895	1,446	12,649,220	3s. 4d.

A breast cutting chain machine, such as is used very largely in the States, is officially stated to have undercut 1,700 square feet in 9½ hours, or 7½ minutes to each cut 6 feet deep and 44 inches wide, including the moving and setting of the machine.

Messrs. D. Bruce Peebles & Co.—We hear that this firm has secured the following municipal contracts:—Barrow-in-Furness, steam dynamo and accessories, total value of contract, £3,154; Southampton Corporation, balancers and boosters (section A), amount of contract, £2,070; Warrington Corporation, steam dynamos, Willans engines, total amount of contract, £6,788.

The Lancashire Dynamo and Motor Company, Limited.—As announced a fortnight ago, we have received a catalogue from the Lancashire Dynamo and Motor Company who are building a large works in Trafford Park, Manchester. This company was registered on April 11th, with a capital of £100,000 privately subscribed. The general manager is Mr. A. P. Wood, who, until recently, was an engineer with Messrs. Mather & Platt, Limited, in whose employ he had a considerable amount of experience both in this country and abroad. The company will manufacture continuous current and polyphase generators up to 3,000 H.P. in size, tramway motors, rotary converters, balancers, boosters, enclosed motors, &c. The latter, up to 50 H.P. in size, will be manufactured to stock on the interchangeable plan, all parts being sent to the stores to be tested on the measuring machines, and afterwards assembled as required. This system ensures uniformity in the various parts, so that should any breakage occur, the defective portion can be sent on receipt of a wire, and will *fit* into its place. These motors have been specially designed to meet the demand for a first-class reliable machine. They are especially suitable for working in damp and dirty places, and can be secured in almost any position. The motor can be readily fixed on the floor or the ceiling as required; in the latter case the end bearings are simply turned round, so that the oil wells are below. They may be used in oil mills, cotton mills, flour mills, dye houses, coal mines, iron foundries, shipbuilding yards (out in the open), and for cranes and hoists of all descriptions, &c. The armatures are slot drum wound of the straight cut type, each coil being separately wound on a former and taped up before being fixed in position on the armature. The windings at the back are protected by a brass shield, so as to effectually exclude oil or dirt. The commutator bars are of hard drawn copper insulated with specially selected mica. The bearings are of the swivel self-oiling type, each fitted with two oil rings. Special attention has been given to the design, so that oil cannot travel inside to the armature. The brushes are of carbon, and run sparklessly at all loads without being moved. The magnets are of cast-steel with laminated pole pieces to reduce eddy currents. The windings are former-wound and taped, dipped in insulating composition and baked. The machine tools and labour-saving devices, which will be all electrically driven, are the best that can be purchased, and the arrangement of the same will be such that work of the highest class can be expeditiously, accurately, and economically turned out. The works will be ready and completely equipped in six months' time, the contractors for the various portions being under a heavy penalty to complete in this period. Owing to the large number of orders on the books, it has been found necessary to commence manufacture in temporary works. The company's offices are located in Corn Exchange Buildings, Fennel Street, Manchester, pending the completion of the more commodious premises in Trafford Park.



Lancashire Dynamo and Motor Company's Motor.

Easton, Anderson & Goolden, Limited v. New Brighton, &c., Tower Company, Limited.—In the High Court last week this case came on for hearing. The plaintiffs claimed £4,794 for supplying electric lifts and a pump for the New Brighton Tower, already described in the Electrical Review. According to a report of the case in the *Times*, defendants admitted the greater part of the claim, subject to a counterclaim by them for £5,264 as damages for delay in completing the machinery which plaintiffs had contracted to erect. The case occupied the whole of the 3rd inst., and on the 4th a settlement was arrived at, in accordance with the terms of which the jury returned a verdict for the plaintiffs for the amount claimed; and they also gave a verdict for the defendants on the counterclaim for £600.

Electric Construction Works.—The directors of the Electric Construction Company, Limited, have just commenced extensive and important additions to their works at Bushbury, near Wolverhampton.

Electric Light Fitting.—The Edison & Swan United Electric Light Company send us a pamphlet respecting a new automatic wind-up apparatus (Killingworth Hedges' patent), which they

Digitized by Google

have just brought out. It is claimed to meet the general demand for a simple and reliable method of raising or lowering lamps suspended by flexible cord, so that, according to the requirement, the light may be brought to any desired position, and to bear upon any particular object. This facile movement is obtained without the use of "counterweights" or the arrangement of lengths of flexible cord. It is also well adapted for use with table and floor standards. The winding gear consists of a porcelain drum, on the ends of which are mounted the brass terminal plates to which the flexible cord is connected The drum is used in connection with and revolves centrally on a porcelain base, the latter being provided with terminals to which the leading-in wires are brought and which form the supports for the drum when connected with the terminal plates fixed on its ends. The flexible wire is wound up on the drum by means of a spring, and is controlled automatically by a small stop or peg fixed on one end of the drum and caught by means of a small ratchet wheel. When the flexible cord is withdrawn from the fitting to the desired length, all that is necessary is to allow the same to slowly and gently slide back with the guidance of the hand, when it will be found that the ratchet wheel has caught the peg or stop, thus preventing the drum from winding further. The same operation is repeated when a further length of flexible cord is required to be withdrawn. When desired to wind up the flexible wire a short pull of the flexible releases the peg or stop from the ratchet wheel, when it will be found the cord will fly back and re-wind itself round the drum. This form of wind-up can also conveniently be used in connection with hand lamps or similar portable fittings, as the fitting can be hung by the side of the wind-up apparatus when not in use, taking up little space and doing away with the necessity of a loose coil of flexible wire, which is invariably in the way.

The Electric Welding Company, Limited.—In the Chancery Division of the High Court of Justice on Friday (August 4th) Mr. Farwell, Q.C., said he had a motion to rectify the register of this company, but there was a possibility that the case would be settled, and he therefore asked that the motion should be allowed to stand over generally, with liberty to restore it upon application. Mr. Justice Byrne assented.

Fan Motors.—The Stewart Electrical Syndicate, Limited, send us a price list of the "Hurricane" fan motors (direct current) for which it has just been appointed sole agents in the United Kingdom. No extravagant claims are made for high efficiency, but it is being put on the market as a thoroughly good and reliable piece of apparatus, cheap, strong, and simple. The fan and motor rest on a universal ball joint, which is controlled by a screw sufficiently large to be conveniently operated by hand. The simplicity of this device permits the fan to be easily directed toward any point where it is most desirable at the time to throw the breeze.

Fire.—We are glad to learn that the fire at Henley's Telegraph Works was limited to the submarine cable department, and will not cause more than a week or two's delay in the execution of work of that particular class. The company are to be congratulated upon the efficiency with which they have organised their workmen to deal with fires either by night or day. The fire in question occurred late on Saturday night, and it was mainly due to the promptitude with which the workmen brought the hydrants and pumps to play, that the scope of the fire was limited to the one shop, and the work of the Fire Brigade in finally extinguishing the flames was thus rendered considerably easier.

High Speed Engines.—Messrs. Reavell & Co., Limited, of Ipswich, send particulars of their high speed enclosed constant thrust compound engines (Scott's patent). In the front of the list is an illustration of one of their two-crank engines coupled to a Crompton dynamo at the Islington Vestry electricity works. Messrs. Reavell have recently erected extensive and well-equipped works for the construction of these engines which are made in standard sizes, single and two-crank, and also as a three-crank engine. They are claimed to be specially suitable for direct coupling to dynamos, for electric lighting, traction, and other electric power purposes. We understand that a good number of these engines are now running in public and private installations. Instead of employing two cylinders as in an ordinary compound engine, the feature of the Scott engine is that the first stage of expansion takes place on the top of the piston, and the second stage on the bottom of the piston in one cylinder. Facilities are afforded at the works for the complete testing of the engines with purchaser's dynamos, at full load. The list before us gives a general description accompanied by an explanatory illustration of a single-crank engine. We do not doubt that Messrs. Reavell will be pleased to send a copy of the pamphlet to all inquirers.

Holiday Tours.—Those of our readers with whom the holidays are among joys yet to come, are recommended to peruse an interesting little pamphlet issued by the Great Eastern Railway, which gives views of some charming scenery in the Thuringian Mountains, and the Harz, including the sacred spots which once knew the tread of the celebrated Luther, and where some of his relics are yet to be found.

The L. B. & S. C. Railway is also circulating a very attractive "South Coast Quarterly," in which are illustrated some of the best coast line and "cross country" resorts within the area of that railway's service, where one may while away the idle hours of the holiday vacation.

Liquidations, Dissolutions, &c.—A meeting of the Improved Incandescent Electric Lamp (Foreign Patents) Syndicate, is to be held at 20, Jewry Street, E.C., on Saturday, September 9th, to hear an account of the winding-up from the liquidator, Mr. R. Ballard.

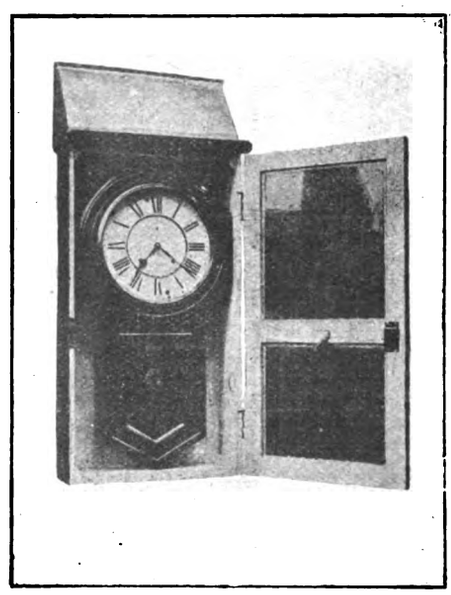
On Wednesday the petition filed by the Electric Construction Company for winding up the Madras Electric Tramways, was heard in London, and was ordered to stand over until the first petition day in November. If nothing has been done in the meantime, a compulsory order will be made.

New Electrical Works.—It is stated in the *Manchester Courier* that Messrs. Mather & Platt, Limited, the well-known electrical engineers of Salford, have taken over 40 acres of land near the canal and railway at Agecroft, in the township of Pendlebury, for the purpose of erecting modern workshops to meet the increasing demand for their various specialities in electrical plant. The proposed new works are situated near the Agecroft Collieries.

Personal.—It is stated in an American contemporary that Col. J. C. Bonner has left Toledo for England, in the interests of his rail waggon, a number of which have already been shipped to the Isle of Man. This order is considered to give the waggon a foothold abroad, and Mr. Bonner intends to see that they are placed in good working order and given a fair trial. Our contemporary adds:—"An effort is also being made to establish the waggons on an electric line in Birmingham, and this matter will take Col. Bonner to that city."

Smoke Nuisance.—The London County Council, it is announced, is to take action in regard to the smoke nuisance in London by taking steps for enforcing Section 114 of the Railway Clauses Consolidation Act, 1845, which requires that every locomotive shall be constructed to consume its own smoke, and Section 19 of the Regulation of Railways Act, 1868, which provides that if a locomotive is constructed to consume its own smoke, but fails to do so as far as practicable at the time charged in the complaint, the railway company owning such locomotive shall be deemed guilty of an offence against the section first named.

Time Recording Clock.—Mr. F. J. Borland, of Leeds, is now putting on the market a time recording clock to supply the evident need for a cheap form of apparatus for checking in workmen. The time checks are simply dropped through a funnel which delivers them into compartments of a receiver, the position of which is varied



by gearing connected with the works of the clock. An electrical attachment to ring a warning bell can also be attached when required. The whole arrangement is simple, and as long as the clock is going, cannot fail to act. The price is extremely moderate.

Trade Announcements.—We are informed that Mr. H. Binko, late managing director of Binko, Ridsdale & Co., Limited, has resumed his old established business as electrical engineer and manufacturer, at 34, Leadenhall Street, E.C., under the former style of H. Binko & Co.

Messrs. H. W. Sambidge & Son, of Birmingham, manufacturers of electric light fittings in brass and wrought-iron, have opened London showrooms at 19, Farringdon Avenue, E.C. We have received a small fittings circular such as the firm is sending out to its customers.

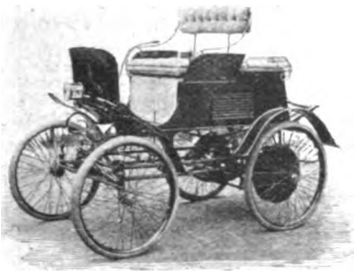
The London Battery Company, of Westminster, announce that they have disposed of their business to the Atlas Carbon and Battery Company, Limited, Ewer Street, London, S.E.

Messrs. Geipel & Lange notify that owing to the rapid increase of their business, they are removing to new and larger offices at Parliament Mansions, Westminster, to which all communications should in future be addressed. The same remarks apply to the trading and contract business of Messrs. Paterson & Cooper, which was taken over by Messrs. Geipel & Lange, and forms a part of their business.

Waverley Electric Car.—In our recent review of the motor-carriage exhibits at the Royal Agricultural Hall Exhibition, we omitted to notice the Waverley "Ran about" of the Automobile Association, Limited. We are given to understand that this car is

Digitized by Google

able to take gradients of 1 in 10, to run an average of 40 miles with one charge and at speeds up to 16 miles an hour. It is claimed to be silent, economical, and low priced. The "Run-about" weighs 12 cwt. and the "Stanhope" 13½ cwt. The motor is of the multipolar type carefully designed for overloads, it is rigidly hung to the frame of the running gear, and it and all gears are carefully covered, amply protecting them from dust and water, so that in cleaning the carriage only moderate care need be exercised. The motor shaft is geared directly to the two rear wheels by a single reduction. Each rear wheel is made to revolve independently of the other by compensating



gears placed in line with the motor shaft. The motor is of 1½ H.P. and the battery employed, said to be covered by broad patent claims, is of a new type, and less than half the weight of the storage cells used in other cars of the same capacity. The normal discharge rate of the battery is about 15 amperes, at which rate the car runs at a speed of from 12 to 14 miles an hour. One simple ratchet lever is all there is for the manipulation of the car, five ahead and three astern speeds being provided. The controller contacts are sliding and self-cleaning, and so constructed that burning at these points when shifting the speed circuits is prevented. A band brake will stop the vehicle in its own length at full speed. The frame work is tubular, all wheels have ball bearings, pneumatic tyres, and wire spokes, and the whole car runs therefore as easily as possible. This car is turned out as "Run-about," with seating capacity for three, and as "Stanhope," for two persons, with hood.

X Rays on the Stage.—In a melodrama recently produced in suburban London, entitled "Thou shalt not kill," the X rays are employed to locate a bullet. As the conditions of the theatre are not exactly suitable for the actual use of coil tube and screen, Messrs. Harry W. Cox, Limited, were entrusted with the work of devising an efficient substitute. This they have achieved most successfully, and the effect was quite easy to mistake for the real thing. The manager of the company carries round a complete X ray outfit, which is exhibited during the day, tickets being distributed at the evening performances.

ELECTRIC LIGHTING NOTES.

Barnsley.—The Town Council will apply to the Local Government Board for sanction to a loan of £3,000 for extensions of the electricity works.

Blackburn.—Major-General Crozier, R.E., an inspector of the Local Government Board, held an inquiry on August 1st, relative to the application of the Blackburn Corporation for power to raise loans of £25,000 for the purpose of electric lighting.

Bolton.—The electrical engineer, Mr. A. Ellis, has reported to the Electricity Committee on the subject of street lighting. He prefers the rectifier system for Bolton, with the arc lamps mounted on every second pillar, 80 yards apart, and two 16-C.P. lamps on every post, 40 yards apart. The latter would replace the arcs at midnight. The price per annum would be £18 per arc at 80 yards, £16 at 60 yards, and £15 at 40 yards; while the glow lamps would cost £2 2s. per annum per 16 C.P., including renewals, as against £2 5s. for gas.

Bristol.—On August 3rd an accident occurred at the Central Electric Lighting Station to H. J. Arnold, a linesman in the employ of the Corporation. He was engaged in some work on the switchboard at the time, and it is assumed that in reaching for something he inadvertently touched the high pressure terminal and received a shock, resulting in severe burns. Artificial respiration was resorted to successfully, and the injured man, who had also had a bad fall, was removed to his home. It is intended to find accommodation for him in the General Hospital, and it is hoped that he will speedily recover.

An exciting incident took place last week in Nelson Street, where the electric cable is being laid. The workmen had left one of the drums standing in Broad Street, and by some means or other it started rolling down the slope, and crashed into a public house, completely demolishing the front of the premises. Several persons had narrow escapes, but fortunately, no one was injured.

Carlow.—The overhead wires of the electric supply network have been replaced by underground cables by Major Alexander, the proprietor of the works.

Ceylon.—The Colombo Council has accepted Messrs. Boustead Brothers' undertaking for the electric lighting of the tramway routes, and a contract has been entered into. Messrs. Boustead Brothers undertake to supply and erect, at their own cost, an installation of 88 arc lamps, of 10 amperes capacity each, along the Grandpass and Maradana tramway routes, commencing in each case from the point where the Fort arc lighting ends. These lamps will be mounted on carriers on the top of the tramway posts, and will be an average distance of about 120 yards apart over some six miles of streets, which will afford a very efficient and handsome illumination of the roads in question. The firm also undertakes to supply the current for these lamps, carbons, trimming and attendance, all supervision, maintenance and repairs, for the sum of 13 cents per lamp per hour, provided the Council agrees to the following conditions:—(1) Agreement to be for period of tramway agreement. (2) The Council to have the option of acquiring the installation and the necessary plant from us at the expiry of the agreement. And (3) the Council, in the event of its being decided to take over the tramways, to further agree to take over this installation and the necessary plant also in good order and condition, it being held to be reasonably modern and up to date. This point to be decided upon by arbitrators appointed for the purpose in the usual manner, and such arbitrators shall also value the plant and installation, should it be decided that the Council shall acquire the same. Messrs. Boustead Brothers have been granted permission to run electric launches on the Colombo Lake and to erect landing stages at different points.

Cleethorpes.—The District Council has resolved to procure a provisional order for the supply of electricity for lighting and traction.

Clewer.—The Parish Council is considering an application from the Windsor Electrical Installation Company to lay cables in their parish.

Continental Notes.—FRANCE.—The establishment of a central station in the town of La Mothe-Saint-Keraye (Deux Sèvres), has just been decided upon.—A company has been formed at Lyons (11, Rue de l'Hôtel de Ville), with a capital of £110,000, to be known as La Société Electro-Chimique de la Romanche.

GERMANY.—According to the official statistics of the empire, just published, it appears that 13 per cent. of the cities of Germany practice municipal ownership of electric light plants. Of the cities with a population of more than 10,000, 517 in number, 120, or more than 23 per cent, own their own electric lighting plants. Of the 2,700 smaller cities, 300, or 11 per cent., have municipally-owned plants.

Derby.—The Town Council has reduced the charges for electricity from 6d. per unit for the first 1½ hours of maximum demand and 3d. afterwards, to 6d. for the first hour and 3d. afterwards. The £400 deficit of last year has been changed to a surplus of £789, and the demand is increasing rapidly.

Dover.—The trolley wires were struck by lightning recently during a heavy storm. Beyond throwing out the circuit-breakers and stopping traffic for a few minutes, no harm was done.

Dudley.—The Town Council, at a special meeting on August 2nd, adopted the recommendation of the Railway, Tramway, and Electric Lighting Committee to obtain a loan of £33,000 to carry out a scheme of electric lighting for the borough.

Durham.—The electric lighting provisional order having been confirmed by Parliament, the Town Council has resolved to consult Mr. Hawtayne on the subject, and to negotiate for the transfer of its powers to a company.

Eton.—After a battle, which has lasted upwards of two years, the advocates of electricity for street lighting on the Urban District Council have defeated the opposition, several of whom are shareholders in the Gas Company, and on Thursday, last week, the tender of the Windsor Electrical Installation Company was accepted to light Eton with the electric light. Originally, Eton was supplied with 72 gas lamps with a candle-power of 1,460 at an annual cost of £303 18s. This will be replaced by 12 500-C.P. arc lamps and 42 16 C.P. incandescent lamps, equivalent to 6,672 C.P., at a cost of £336 5s. Thus, for an increased expenditure of £32 7s. per year, there will be an additional candle-power of 5,212.

Exmouth.—On Mr. Hammond's advice, the District Council has decided to apply for a provisional order.

Fife (N.B.).—At a meeting of the St. Andrews District Committee of the County Council on July 31st the Tayside Electric and Gas Light Company and the Newport Gas Light Company gave notice that they intend to apply to the Board of Trade for a provisional order to authorise the supply of electricity within the parish of Forgan.

Godalming.—The Town Council has accepted the offer of Edmundson's Electricity Corporation, Limited, to take over the Council's provisional order for public and private electricity supply. The Council has the option of purchase at the end of seven years for a sum equal to four-thirds of the capital expended, or after 14 years for five-fourths of the capital, or any time after seven years upon payment of the capital plus a sum sufficient to make up the dividends paid by the company to 10 per cent. per annum from the start down to the time of purchase.

Digitized by Google

Hampstead.—The annual report and statement of accounts of the Hampstead Vestry's electric lighting installation shows that the total capital raised was £126,570; during the year 1898-99 over £11,000 was spent on new machinery and nearly £7,000 on new mains, together with £2,200 on new buildings. The income for the year was £24,377, an increase of 53 per cent. on the preceding year. The gross profit was £13,014, and the net profit £8,339, or 6·65 per cent. on the total capital expended. It is proposed to invest £7,500 of this in Government stock as the nucleus of a reserve fund.

Hereford.—The County Council proposes to supply electricity on the following terms:—For the first two hours per day, 6d. per unit; for each hour afterwards, 4d. per unit; for motive power, 3d. per unit; for hire of meter and M.D. indicator, 4s. per quarter.

High Candle-Power Incandescent Lamp.—According to the *Marine Engineer*, the Bryan Marsh Company of New York has been experimenting with incandescent lamps, which are greatly superior to arc lights in a fog, since the yellow rays of the incandescent light are not so easily damped out and absorbed as the rays of the arc light. The company made a lamp of 5,000 C.P. with two filaments, each taking 236 volts and about 3 watts per candle; the lamp thus took about 15 KW. It burned out in three nights, due probably to the intense heat at the neck.

India.—Part of the Madras General Hospital is being lighted with electricity as an experiment.

Mr. B. N. Sen, a native of India, formerly a student of the Sibpur Engineering College, and later engaged with Messrs. Kilburn & Co., has been appointed chief engineer of the Calcutta Electric Lighting Co.

Islington.—The long outstanding dispute between this Vestry and the St. Pancras Vestry on the subject of laying mains on the boundary line of the parish was practically settled at a meeting of the Islington authority on Friday. In a report on the subject the General Purposes Committee stated that, in view of an intimation received from St. Pancras that it proposed to lay mains in Brecknock and York Roads for the purpose of supplying current to consumers in St. Pancras, the Vestry referred the matter to the vestry clerk and the solicitor, with instructions to obtain an injunction prohibiting the work being commenced, or to take such other steps as might be necessary for preventing the Vestry from interfering with the roads in Islington; and that subsequently a communication was received from St. Pancras stating that, after reconsideration, it had decided not to give effect to its previous intention of interfering with the roads without permission, but that it was desirous of sending a deputation with a view to some arrangement being come to in the matter. The General Purposes Committee further stated that the deputation duly attended, and admitted that St. Pancras had no statutory power to lay mains in Islington, and that the Vestry had no authority to accord permission to do so. The committee were nevertheless of opinion that too much importance should not be attached to the point, and had consulted the solicitor as to how the Vestry's interest could be adequately protected if the application were acceded to. The solicitor had advised the committee that the matter might be met by the Board of Trade granting a license to the St. Pancras Vestry to supply electricity in the roads in question under Sec. 3 of the Electric Lighting Act, 1882. On the recommendation of the committee the Vestry unanimously resolved to inform St. Pancras Vestry that if it deemed it advisable to apply for such a license the Vestry would be prepared to give consent to its being granted.

Kirkwall.—The Town Council has appointed a committee of inquiry into the question of electric lighting. Mr. Drever moved that it be remitted to a committee to inquire and report whether it be advisable for the Corporation to introduce into the burgh lighting by electricity. He had, he said, no opinion, had no right to have an opinion in view of want of information on the subject, and he approached it with an entirely open mind. He might approve of introducing electric lighting or he might not, but he would like information, and he thought the community would like it. Other communities, including Lerwick, were looking into the subject. The motion would also let the outside public and others know that the subject was being looked into, and would keep private interests from intruding themselves, which, in these days of corporation enterprise should be avoided. Mr. Drever then referred to a letter which had been received by a gentleman in town from Mr. York, the electrical engineer who had charge of the installation of electric light in Fort William, offering to supply any information on the matter. Information might also be got from Lerwick. Dean-of-Guild Flett seconded the motion, which was agreed to, and the following committee was appointed:—Bailies White and Sclater, Dean-of-Guild Flett, and Messrs. Sutherland, Baikie, and Drever—Mr. Drever to be convener.

Llanelly.—The Council has received various proposals for the supply of electricity for lighting and traction, and is considering the question of terms, &c.

Manchester.—A gas explosion occurred in an electrical conduit in King Street on August 8th. No serious damage was done.

Newport (Mon.).—The manager's quarterly report shows cost of generation and distribution per unit, 3 11d., against 4 78d. last year, and total revenue, £1,351 0s. 7d., against £863 4s. 5d. last year. The number of lamps connected and on order is equivalent to 30,318 8-C P.

Paris.—A daily paper says that two offers to light the Bois de Boulogne by electricity have been laid before the Council by private individuals, M. Mildé and M. Tavernier. M. Mildé proposes to set up an electrical installation, but not at his own expense, the cost to be spread over 14 years. For furnishing the light and maintaining the works he asks for an annual subsidy, much smaller than the amount which the city would have to lay out if it undertook the work itself. M. Tavernier asks for a similar subsidy, but is willing to erect the necessary plant at his own expense. The cost of lighting the Bois is estimated at about £2,000 a year.

London, E.C.—The chairman of Milner's Safe Company, Limited, last week told the shareholders that they had carried £7,000 to reserve for the electrical equipment for which they had contracted. It was a large outlay, but was necessary to keep the works up to date. A large saving would result by the introduction of electricity for driving all the machinery and lighting the buildings.

The following letter appeared in the *Pall Mall Gazette* on 3rd inst.:—

Sir,—The report of your interview with the City Company gives a fair idea of the situation created by the decision of the House of Lords giving the right to compete to the Charing Cross Company. That decision has brought about—perhaps somewhat prematurely—a condition which I foreshadowed in a letter published on June 20th, which, after referring to the immense outlay necessary, goes on—

Then what happens? The Charing Cross Company will offer for 5d. what the City of London Company offers to supply in January for 6d. But when the former company is ready, the latter will then come down to 5d. The effect of this would be to ruin the Charing Cross Company by rendering their outlay unproductive, for is it likely that City consumers will put up with all the nuisance involved in changing over to a new company when they will be having the same thing at the same price from the old company?

The City Company has taken a much bolder step than I anticipated. It has come down to 4½d., and that, too, before the Charing Cross Company has laid out 1d. in the City. This move has entirely knocked the bottom out of any hope of success that may have hitherto buoyed up the Charing Cross Company. But a far graver issue has yet to be fought—namely that of the validity of the contracts between the Corporation and the City Company. If they are valid, competition is impossible. If they are not, an action for damages will lie against the Corporation by the City Company.

The City Company has given the Corporation the opportunity of getting out of this "cleft stick" by buying up the whole concern at a price which will yield about the same figure to the ordinary shareholders as that at which the last issue of shares took place—namely, £ 8, and at an immediate profit to the ratepayers of £45,000 per annum. It is a pity the Corporation does not avail itself of this offer.

J. W. Martin.

The *Pall Mall Gazette* has now interviewed the Charing Cross and Strand Electricity Supply Corporation with a view to hearing its side of the City electric lighting question. The interviewer found the company in a state of restrained triumph. The action of the City Company in reducing the charge to 4½d. per unit seemed premature by at least 18 months; it seemed like cutting off the nose to spite the face. But the suggestion that the Charing Cross Company will be thereby deterred from following out its design is far-fetched and unfounded.

When the Charing Cross Company has made up its mind, it is not in the habit of changing it. The company, our representative was assured, means to go into the City. Its entry to the Strand proved a good thing for all parties: the reduction in the price of electricity led to an enormous increase in the number of lamps. Why should not something of the same sort happen in the City?

As for anything in the nature of collusion between the Corporation and the Charing Cross Company, our representative was assured that there had been nothing whatever of the kind. On the contrary, the Corporation attempted to impose conditions by no means favourable to the company. In some instances, the Corporation was successful, but in the case of the restrictive conditions proposed by the Board of Trade, not one of them was allowed to stand. In everything, except the calling of witnesses, the Corporation behaved kindly to the City Company. To talk of the Lords' decision being upset in the Law Courts is absurd. The Charing Cross Company is working under Act of Parliament, a sort of thing which is not usually upset in the Law Courts.

Had it been decided that the agreement between the Corporation and the City Company was valid, the Electric Lighting Act of 1888 would *ipso facto* have been stultified. That Act specifically precludes monopoly. Moreover, the very fact of the Corporation having tied its hands by entering into this agreement precluded it from being in a position either to give or withhold its consent to the introduction of competition. The very words, "so far as we are able," with which the Corporation qualified the undertaking to exclude competition should have enforced these facts upon the attention of the City Company's directors. Also, that limitation should have been brought under the notice of intending shareholders.

Throughout the contest the Charing Cross Company has behaved in a scrupulously fair and straightforward manner; there has been nothing whatever in the nature of backstairs procedure, and nobody has been able to suggest that there has, let alone support the suggestion.

Rio de Janeiro.—The gas company of Rio de Janeiro has been successful in securing an extension of its privilege for the lighting of the city by gas until the year 1940. From July 1st it also secures the right to supply electricity to the year 1915. The distribution of electricity is to be by underground cables, and the public lighting will be by arc lamps.

Ripley.—The District Council has received two tenders from experts for surveys and reports on the electric lighting of Ripley; that of Messrs. Page & Medhurst, of Manchester, for 30 guineas, was accepted. Has it come to this, that consulting engineers nowadays bid against each other, cut prices, and so on? How are the mighty fallen!

Sheerness.—The District Council has resolved to offer no opposition to the Electrical Power Distribution Company's application for a provisional order for the installation of the electric light at Sheerness.

Sevenoaks.—The District Council is considering the question of electricity supply in the district.

Sheffield.—The trade unions continue to pass resolutions hostile to the Lighting Committee's contract with Messrs. Ferranti; we sincerely trust that the committee will stand fast, and that the Council will support its views of what constitutes "a fair contract." All honour is due to Messrs. Ferranti for their stubborn resistance to what is really an underhand renewal of the question of the strike—shall an employer be master of his own workshops?

The difficulty arose through the refusal of Messrs. Ferranti to insert the so-called "fair wages" clause in their contract for electric lighting machinery for the City Council. This clause has been included in all municipal contracts in Sheffield for several years, but

Digitized by Google

the Electric Lighting Committee decided to make an exception in this instance. The clause enforces the standard rates of wages and hours recognised by the local trade unions for all work done in Sheffield, and, for work done elsewhere for use in Sheffield, the minimum standard rates recognised by the societies where the work is done, under penalties. It should be observed, however, that a clause enforcing the hours and wages recognised by the Masters' Federation and the Men's Trades Unions for the Oldham district was embodied in the contract, with free access to works and wages books on the part of the engineer to the Corporation. The present contract is for a 1,000-KW. steam alternator costing £9,500, and a new switchboard, which is to cost £1,500. Messrs. Ferranti have already supplied plant of about 1,800 H.P. to the city.

As we go to press we hear that the Council has endorsed the action of the Committee by a majority of three votes. We congratulate Messrs. Ferranti on their victory.

Southend.—At a Council meeting held on July 12th, it was decided to refer to the ratepayers and residents the proposed transfer of the electric lighting powers to Mr. A. H. Gibbings, whose terms were considered to be more favourable than those of any other party offering. The Council voted 9 in favour of deferring the matter, and 11 against, after which the resolution was agreed to calling upon the town to express its opinion, and referring the matter back to the committee for that purpose. The public meeting was duly held last week, 120 persons being present, and by 40 votes to 30 it was resolved "that it is in the best interests of the town that the Corporation should carry out the order *if carried out at all*." It seems that there was no one present who knows much about the matter, or the absurdity of the last five words would not have escaped attention. The ratepayers, fortunately, are not the controlling authority, and the Board of Trade will, in keeping with its recent vigorous policy, see that the Council is not permitted to sit indefinitely upon its order, while private parties are willing and anxious to turn it to account. There is nothing more unsatisfactory than calling public meetings to settle such a question as electric lighting, particularly in the height of the seaside season, when there is difficulty in getting the right people together. A general poll is better, but not much, for we question whether 9 out of every 10 residents are well enough informed to vote wisely. We do not know to what extent the Council will consider itself bound to abide by the ruling of its constituents, but whoever does the work, it is to be hoped that the delay will not be further prolonged. A good deal of nonsense was said about Mr. Mitchell, the borough electrical engineer, having been connected with Mr. Gibbings at Bradford. The fact is, that Mr. Mitchell was chief assistant electrical engineer at Bradford from 1889 to 1894, and Mr. Gibbings was not appointed to Bradford until 1895.

Stalybridge.—The District Council proposes that a joint scheme of lighting and traction should be entered into by Ashton, Stalybridge, and Dukinfield.

Surbiton.—The District Council has decided to lease its provisional order to Callender's Cable and Construction Company, Limited. The Council will find the capital, and the company, in return, will pay interest on the sinking fund. The Council has the option of taking over the undertaking at the end of five years, paying a premium of 2 per cent. per annum.

Torquay.—The Princess Pier and Gardens and the Haldon Pier are to be electrically lighted at a cost of about £620.

Wallsend.—The Royal assent has been given to the Bill of the Walker and Wallsend Gas Company to authorise them to supply electricity in Wallsend, Willington and Willington Quay.

Warrington.—Tenders amounting to £50,986 2s. 6d. for the construction of the new destructor premises and plant, the new electric lighting premises and plant, and other works in connection therewith, were accepted by the Town Council last week, subject to the approval of the Local Government Board.

West Bromwich.—The Electric Lighting Committee having appointed Mr. R. C. Quin, of Blackpool, as their consulting engineer, he has prepared a report showing a scheme for the supply of electricity within the compulsory area. The committee recommends application to the Local Government Board for sanction to borrow £30,000 for the purpose of laying down plant and mains.

The Mayor made an important statement at the last meeting of the Council. After congratulating the Council upon having retained their right to supply electricity, he pointed out that had they once parted with that power it would have taken an enormous amount of money to have obtained it again. The demand for electricity in the borough was very encouraging, and they found that in the compulsory area of supply 300 H.P. would be required for generation purposes. For lighting purposes the demand was 171,000 units, and for power purposes 100,000, thus making a total of 271,000 units, but that did not include the quantity that would be required for working the trams. They had a double track extending for five miles, and for that 300,000 units of electricity would be required, whilst another 50,000 would be utilised on the Spon Lane and Bromford Lane routes. After referring to the proposed charges to consumers, he said that there was a good demand for electricity outside the compulsory area, and that the prospects of the success of the scheme were very bright.

Worcester.—Mr. E. A. S. Fawcett, A.M.I.C.E., Local Government Board Inspector, held an inquiry last week into the application of the Council to borrow, with other loans, a sum of £3,000 for electric lighting purposes.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Barnsley.—An inquiry was held at Barnsley on August 2nd, by Mr. G. A. R. Fitzgerald and Col. Boughey, Light Railway Commissioners, into the application of the British Electric Traction Company, Limited, for powers to construct light railways in the district. Evidence having been given, the Commissioners announced that the application was granted with regard to railways from Barnsley to Worsborough and Monk Bretton, but a third railway, to Huddersfield Road, was struck out on account of the narrowness of Church Street, through which it would have passed.

Birmingham.—Messrs. Brown, Marshalls & Co., Limited, have adopted electrical driving in place of steam.

Bombay.—The Bombay Tramways Company contemplates an early application of electricity upon its lines. The overhead trolley system, which is stated to have worked for three years at Madras and Colombo, and is about to be introduced at Calcutta, is proposed. The managing director of the company has addressed a letter to the Municipal Commissioners extolling the virtues of the trolley as compared with the other systems of traction. A correspondent at Bombay writes to us expressing the opinion that this is a fitting opportunity for electrical firms to start there. An agent of Messrs Siemens is arranging to start electric lighting there as soon as he can obtain the Government sanction, he having received a number of promises to take current from hotels, &c, and there is every prospect of the concern being a success. Bombay is anxious not to be behind Calcutta and Madras. The gas company has at present a good hold on the town, though there are some 30 or 40 separate electrical installations, besides a large number of cotton mills which have their own plant.

Bristol.—The Bristol Tramway Company has recently signed a contract with the British Thomson-Houston Company, Limited, in connection with the large extensions now in progress. The order includes four 500-KW. tramway generators coupled direct to vertical cross-compound engines of the Corliss type, together with three 30 KW. motor generators, and two 50-KW. lighting machines; a complete switchboard for this machinery, and 150 single truck double-deck cars complete, each of which will be equipped with two G.E.-52 motors, series parallel controllers and magnetic brakes.

Burgdorf-Thun Electric Railway.—Switzerland possesses electric tramways as well as electric mountain cable railways in plenty, but a full-gauge railway worked by electricity, capable of accommodating a considerable passenger and goods traffic and over whose lines the through traffic from other railways can pass, forms a new departure. This line, which runs from Burgdorf (on the Great Central Railway) to Thun, in the Bernese Oberland, was opened for traffic last month. The gauge is the usual one for all Swiss through lines—namely, 1·435 metres—so that all the rolling stock of other lines can pass over it. The motor-cars, with accomodation for passengers, weigh 32 tons; the ordinary light passenger carriages, to be drawn by either motors or electric engines, weigh a little over 10 tons. The contact between the car and the overhead cable, which works at a pressure of 830 volts, is effected by a stirrup, held up by two poles. The power is supplied by an overhead line at 15,000 volts, from the new electric power works on the river Kander, in the Bernese Oberland. The 12 trains which pass over the new line in either direction daily consist usually of a motor and a light car. The electric engines, which on emergency can also be used for passenger trains, are intended to cope with the goods traffic, and are capable of drawing 120 tons over the whole line, including gradients up to 1 in 40. The journey from Burgdorf to Thun takes 1½ hours, and opens up some fine hilly country, studded with prosperous farmhouses and rich villages, hitherto almost unknown to the thousands of tourists who visit Switzerland every year.

Canadian Niagara Power Company.—The Government of Ontario has ratified a new agreement with the above company, under which the monopoly clauses are cancelled, and a new rental has been fixed. Other companies are now free to enter the field, and five or six are already organised for that purpose. According to the new agreement the company must have completed by July 1st, 1903, water connections for the development of 25,000 H.P., and must have 10,000 H.P. actually available. The rental will be a minimum of £3,000 yearly, together with 4s. per annum per E.H.P. generated up to 20,000 H.P., 3s. for each additional H.P. between 20,000 and 30,000, and 2s. above 30,000. The company proposes to lay down plant for 100,000 H.P. at least. In the meantime power will be generated and distributed from the Niagara Falls Park and River Railway Company's works, which are the property of the Canadian Niagara Power Company.

Continental Notes.—RUSSIA.—La Société de l'Industrie Minière de Zyrianowsk is installing a large electric power transmission plant at its mines at Zyrianowsk (Alta du Sud). Water-power is being utilised.

HOLLAND.—An electric tramway has been completed and opened for traffic between Haarlem and Zandvoort. The line, which has a length of about 10 miles, has been constructed by Messrs. Siemens and Halske, of Berlin. The plant at the generating station comprises three 170-H.P. steam dynamos.

ITALY.—A contract has been placed with Messrs. Felix Singer and Co., of Berlin, for the construction of about 30 kilometres of electric tramways in and about the town of Catania.

Cradley Heath.—Messrs. Holt & Willetts, engineers and large chain manufacturers, have laid down a plant in their works for electric power to take the place of steam power.

Digitized by Google

Darlaston.—A sub-committee has been appointed by the Urban District Council to consider the desirability of acquiring the portion of the South Staffordshire tramways running from the Bull Stake to Moxley within the Council's district, and to report as to the best means of dealing with the same. A communication has been received by the Council from the Midland Electric Corporation with reference to the supply of electricity, but the clerk has informed the Council that he does not see how it affects them as they do not propose to work their tramways.

Darlington.—The Town Council on August 3rd approved of the scheme of the Imperial Tramways Company for light railways in and about Darlington. The Council has power to purchase the undertaking at the end of 25 years at its then value.

On August 4th an inquiry was held by Colonel G. A. R. Fitzgerald and Colonel Boughey, C.S.I., Light Railway Commissioners, and Viscount Emlyn, assistant secretary of the Commission, into the application of the Imperial Tramways Company for a provisional order for the construction of light railways in and about Darlington. The proposed system would have 9 miles of line, 3 feet 6 inches gauge, and would cost £77,000. The company also applied for a provisional order to lay cables for transmitting power from Stockton to Darlington to work the tramways at 5,000 volts. The County Council, the North-Eastern Railway Company, the Stockton District Council, and the Stockton and Darlington Corporations, were all favourably disposed to the company's application. Mr. Clifton Robinson, managing director of the company, explained the details of the scheme to the Commissioners. An unexpected opposition cropped up on the part of certain ratepayers, who advocated municipal control. A Sunderland lawyer, who claimed to be an expert in electric tramways, was crushed amid laughter by the question: "What is the difference between an alternating and a direct current?"

On August 5th, at Middlesbrough, the Commissioners announced their decision, to the effect that the order would be granted; but they thought that arrangements should be made for the supply of power by the Corporation, in place of transmission from Stockton. The company undertook to endeavour to carry out such an arrangement.

Dewsbury and Spen Valley.—On August 1st Mr. G. A. R. Fitzgerald and Col. Boughey, Light Railway Commissioners, held a public inquiry at Dewsbury into the application made by the British Electric Traction Company, London, for powers to construct electric tramways from Dewsbury to Heckmondwike, Liversedge, Cleckheaton, and Ravensthorpe. The inquiry opened at 10 o'clock in the forenoon, and was not concluded until 6 o'clock in the evening. Ravensthorpe, Liversedge, and Gomersal District Councils supported the application. The Corporation of Dewsbury and Batley and the District Councils of Heckmondwike and Cleckheaton opposed. It was stated that Dewsbury, Heckmondwike, and Cleckheaton had agreed to promote a scheme of their own in the event of the company's application failing. After hearing counsel for each authority interested and a large number of witnesses, Mr. Fitzgerald said it seemed to be admitted on all hands that a light railway would be useful to the districts. They did not ignore the weight which ought to be attached to the views of the local authorities, but, having regard to the division of opinion which existed, they were prepared to grant the order to the company. The company, however, should consider the desirability of conceding to the local authorities the right to break up their own streets where it was desired, and in other respects the Commissioners felt that the company, in adjusting details, should pay regard to the wishes of the various authorities. An undertaking in accordance with the Commissioners' suggestion having been given by Mr. Balfour Browne, the inquiry terminated.

The Dublin Trolley Mishaps.—In the House of Commons last week Mr. Patrick O'Brien asked the President of the Board of Trade whether he was aware that three passengers on an electric tramcar in Dublin on Sunday last were injured by the breaking of the electric wires, which was caused by a passenger pulling the trolley rope in mistake for the bell rope to stop the car; whether he was aware that Mr. Mahony, the magistrate before whom a police charge was brought arising out of the accident, censured the tramway company for exposing the public using the trams to the danger of pulling the trolley rope by mistake for a bell rope, and also censured the Board of Trade for having sanctioned such a dangerous arrangement. Mr. Long (for Mr. Ritchie) replied: "The Board of Trade have entered into communication with the company with reference to this matter. When their reply is received I will decide whether an expert inquiry will be useful. In the meantime I can express no opinion on the subject."

Farnworth.—The District Council has definitely refused to accept the terms offered by the Bolton Corporation for the supply of electrical power for purposes of traction and for lighting, and has decided by a large majority to put down an installation of its own and work both.

France.—Five new lines of electric tramways are about to be constructed in the town of Rouen.

Gateshead Tramways.—At a meeting of the shareholders in the Gateshead Tramways Company, on August 2nd, it was resolved that the proposed Gateshead and District light railway order, 1899, a draft of which had been submitted to the meeting, should be approved.

Glasgow.—A deputation of six or seven members of the Glasgow Corporation visited Dublin last week for the purpose of inspecting the working of the electric tramway system of the Dublin United Tramway Company.

Hull.—The City Council has passed a resolution that the tramcar service be discontinued on Sundays.

Jungfrau Railway.—A further section of this remarkable engineering undertaking has been completed, and was formally opened on August 1st. The tunnel has now been driven through the Rothstock, the rails laid, and the electric conduit fixed for a length of 763 yards from the tunnel mouth below. To make room for a station the rock had to be blasted to the right and left of the upper end of the tunnel. Galleries similar to those in the well-known gorge of the Aare, near Meiringen, have been built outside the Rothstock on its eastern face, so that passengers may enjoy the panorama. The work, says the *Westminster Gazette*, is being continued from the Rothstock right inside the Eiger, and in a year's time the engineers hope to drive the tunnel up to the third station, called beforehand the "Grindelwaldblick."

Lambeth.—The Vestry at the last meeting considered a letter from the London County Council asking for consent to the Council applying to the Board of Trade for a license to introduce the conduit and surface contact systems on the tramways between Westminster Bridge and Tooting. After some discussion it was decided to give the desired permission, on the understanding that all disturbances of the roads were to be subject to the approval of the Vestry's surveyor, and "the pattern subject to the approval of the Vestry."

Leeds.—The Tramways Sub-Committee has decided to request the consulting engineer to invite tenders for 50 more cars, to keep pace with the extensions of the works. There are many cars on order already which have not yet been delivered, owing to the great demand at present existing.

Lincoln.—Mr. Vesey-Brown, the city electrical engineer, has reported to the Town Council on additions and alternatives to the tramway routes on which he reported in May last. The extra cost is estimated at £5,500, additional to the original estimate of £11,137. The Council will apply to Parliament for powers to carry out the scheme.

London United Tramways.—A contract has been signed with the British Thomson-Houston Company, Limited, covering the electrical equipment, engines, cars, trucks, &c., for that portion of the London United Tramways upon which it has been resolved to introduce electric traction, in Hammersmith, Chiswick, &c. The contract includes six 250-KW. 550-volt direct current traction generators and one 94 r.p.m. 5,000-volt three-phase generator, driven by vertical Corliss engines; 13 75-KW. 5,000-volts primary, 330-volts secondary, static oil-cooled transformers; four 200-KW. 500 r.p.m. 530-volt rotary converters; one motor generator set, consisting of a 550-KW. three-phase synchronous motor direct coupled to two 250-KW. direct current generators on combination bed-plate; two 75-KW. 400 r.p.m. 525-volt direct current generators for lighting purposes; and also complete switchboards for the whole plant. One hundred cars of top-seat pattern, each mounted on two trucks and equipped with two G.E. 58 motors. Series parallel controllers and magnetic brakes are also included in the contract. It is intended to have the new service in operation next June.

Manchester.—Messrs. Isaac Storey & Sons, of the Empress Foundry, Manchester, have recently considerably enlarged their works, and have adopted electric driving throughout. The whole of the new arrangements have not yet been completed, but at present there are two main dynamos of 200 amperes at 230 volts each, both being driven from one countershaft with clutches, so that they can be used either separately or together. The engine is of the Proell-Corliss type, of 100 H.P., made by the firm. There is also to be put down a direct coupled plant of about 100 amperes for office lighting and to meet the requirements of overtime working in a small section of the establishment.

Middlesbrough.—Cols. Fitzgerald and Boughey, Light Railway Commissioners, and Lord Emlyn, assistant secretary, held an inquiry on August 5th into the application of the Imperial Tramways Company, Limited, for powers to carry out extensions of their tramways at Middlesbrough. The present application was to run the line through Ormesby, Normanby, and South Bank, nearly to Grangetown. The opponents to the scheme were local landowners. The inquiry was adjourned *sine die*, in order that the parties might arrange terms.

Nottingham.—Messrs. A. Brown, city engineer, and H. Talbot, electrical engineer, have issued their report to the Council on their return from inspecting tramway systems in America. The report contains little that has not already appeared in the technical press, and, as the authors say, "engineers in England have nothing whatever to learn in America as regards the construction of the overhead work of the trolley system." We should like to know why, therefore, do English engineers persist in going to America, when there are first-class overhead systems to inspect at home? Some interesting details of the new power station of the Metropolitan Street Tramways Company, of New York, are given in the report. The estimated cost of the station is about £1,000,000, and it will contain generating plant of 66,000 H.P. There are 87 Babcock and Wilcox boilers, of 500 H.P. each, in three tiers; the chimney shaft is 353 feet high, 22 feet diameter at the top, and weighs 8,840 tons. Storage is provided for 10,000 tons of coal, which will be handled by mechanical conveyors. There will be 8 or 10 sub-stations, transforming from 6,000 volts three-phase to 500 volts direct.

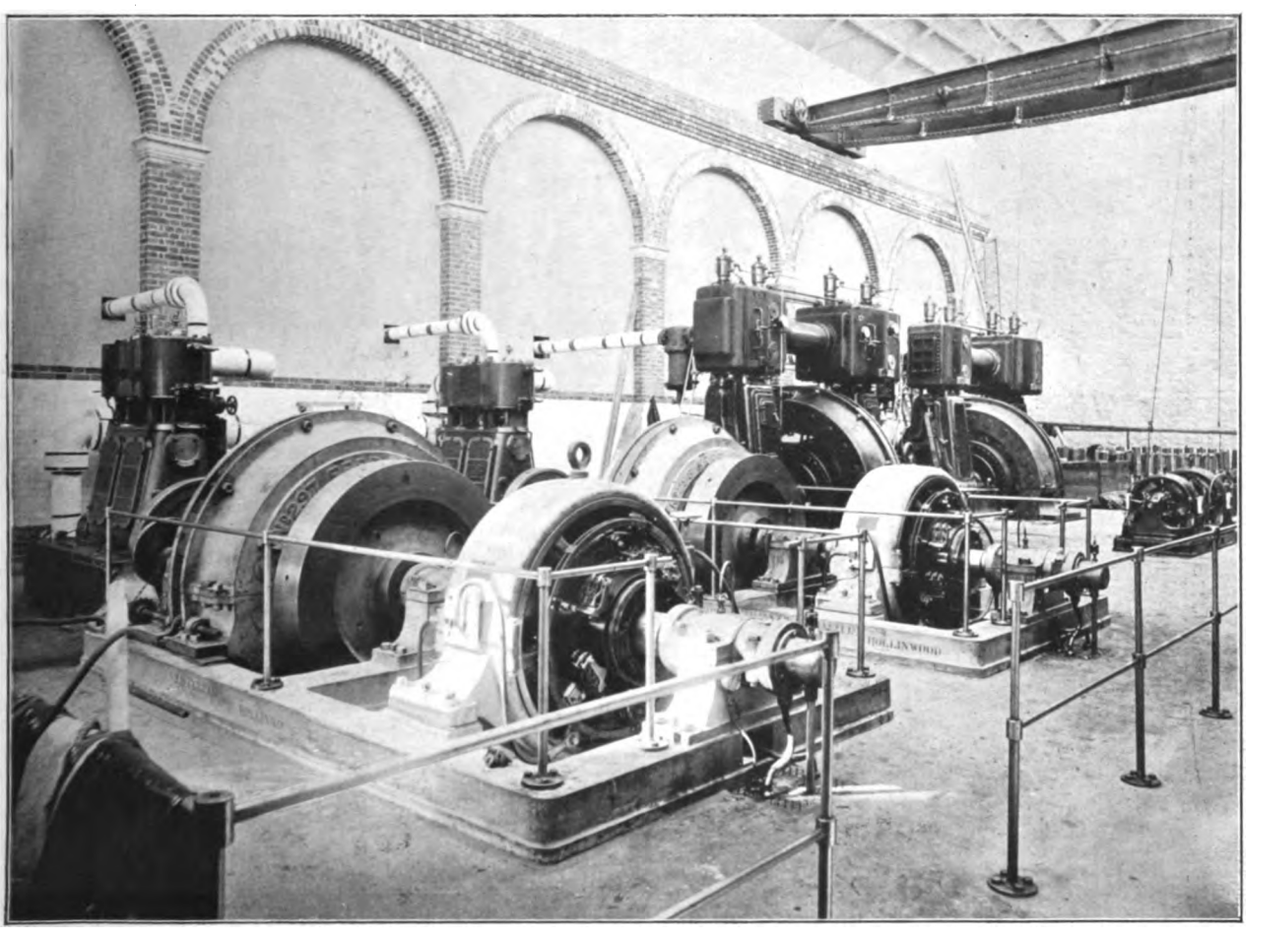
PLYMOUTH LIGHTING AND TRAMWAYS.

At the present moment unusual interest attaches to combined lighting and tramway systems, and though the Plymouth system, which we have recently had the pleasure of inspecting, is not in the front rank as regards size, yet it possesses special engineering features which render it one of the most important plants erected in this country. We believe that the Plymouth combined system was the first proposed in England; at any rate, Mr. Rider, the borough electrical engineer, was one of the first municipal engineers to advocate combining electrical machinery both for lighting and tramway purposes, and on different occasions he has both in the public press and elsewhere advanced the claims of such



General View of Engine Room.

methods. It need hardly be pointed out that opinions are very much divided amongst engineers as to the advantages of placing the necessary machinery for lighting and tramways under one roof and under one management. Much can be urged on both sides of the question. It would seem that the generation of electricity, whether required for lighting or tramway purposes, could be better carried out in one place rather than by duplicating works. In the opinion of some, the force of this argument may appear less from the fact that one of the most important tramways and lighting systems in the kingdom—that of Glasgow—is carried out under distinctly separate managements, and by works which have nothing in common with each other. On the other hand, equally important systems, such as Manchester and Liverpool, are being carried out on contrary methods. It is urged by opponents of combined stations that the tramway system is too important to tack on to a lighting system; but it seems to us that if the electric lighting of any town is properly developed the demand for current for this purpose may be greatly in excess of that required for merely tramway purposes. Moreover, the development of electricity works is in the direction of supplying energy for motors, and in some cases where this has been done signal success has been achieved. Tramway service has much in common with electric motors used for industrial purposes; there is the same proportional fluctuation in the demand, the question of the motor load and lighting load overlapping arise in the same way, and if these difficulties can be successfully met under such conditions, we do not see why the peculiar demand necessary to operate the tramway service should not be equally successfully met. From a municipal point of view, it may be desirable that the management of the tramway system should be distinct from that of electric lighting works; but the most reasonable arrangement would be for the tramways to be managed by a special tramway committee, the lighting committee being responsible, as far as the tramways are concerned, for merely supplying electrical energy. Following on the same lines, it would appear that the electrical engineer should be responsible for the supply of energy and for the supervision of the electrical details of the tramway. The advocates of combined systems have hardly gone beyond that, and it is to be sincerely hoped that

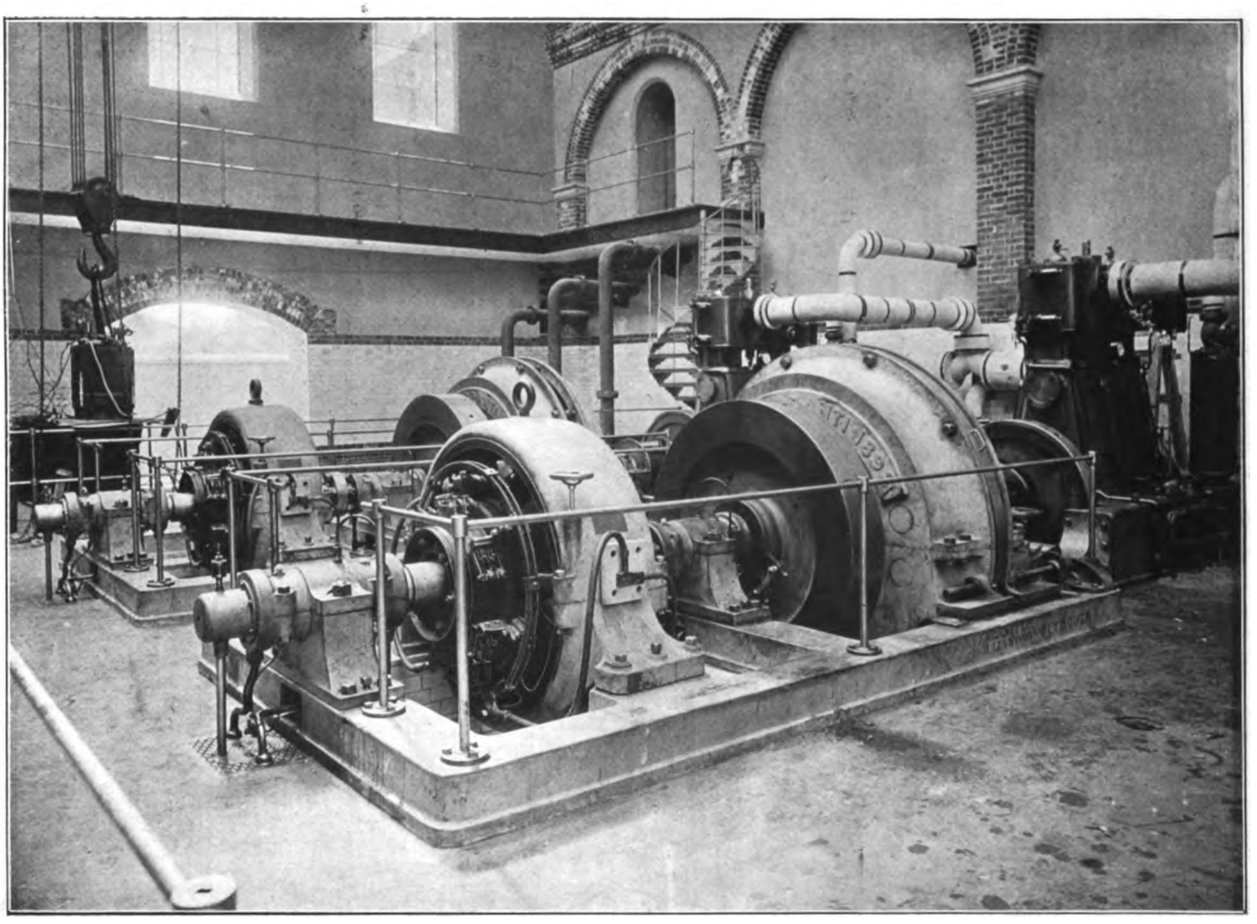
Digitized by Google

the development of municipal tramways will be carried out on somewhat similar lines. We admit that there may be some difficulties in allocating the expenses of generation and distribution, but they are not insurmountable. One important fact is that when a municipality is undertaking electricity supply services (and as they ostensibly work for the common good) no possible harm can accrue from generating electricity for both purposes in one works, assuming the location of the station to be equally good for each.

The Plymouth system, as we have said, is not remarkable for its size, but it possesses, nevertheless, some distinctly interesting details, not only in the arrangement of the generating plant, but also on the tramway side of the undertaking. The lighting of the town is carried out by alternating current machinery, and the necessity of adopting that system has led to a novel arrangement of machinery to which we will refer subsequently. Considerable delay has arisen in starting the works, but the delay has been created through difficulties of the most exceptional character. The site for the works is on the banks of the Cattewater, in close proximity to the famous Prince Rock. The difficulties alluded to arose in making the foundations for the buildings, every single foot of ground being of solid rock and necessitating extensive blasting operations. The station is about 1½ miles from the centre of supply, the building being of plain and substantial structure most conveniently situated both for coal and water. As we have already indicated, the works abuts on the Cattewater, and in addition to enjoying facilities for receiving coal by water, it is connected to the London and South-Western Railway system, a siding in fact being just outside the works.

In a general way the coal for the works will be delivered at the wharf by boat, it being possible for fairly heavy colliers to come alongside. It is the intention of the engineer to erect an automatic coal conveyor, which will carry coal from the wharf to the stores; the latter are arranged in proximity to the boiler house, coal being fed to the boilers by means of shoots and mechanical stokers. The coal will be delivered into the wharf stores, which will have considerable storage capacity, the rest of the operation being carried out by the conveyor. Sea water from the Cattewater is used for condensing purposes, the water from the Corporation mains being used for the boilers. The town's water, by the way, is exceedingly soft, thus differing in character from the water generally obtained on the South coast.

A special advantage possessed by the present site is the ample room provided for extensions, and without the necessity of carrying out any further blasting operations, the present structure could be materially added to. The buildings, erected by Messrs. Pethick Bros., Plymouth, are arranged with the offices in front, the engine house and the boiler house being behind. The engine room is 100 feet long × 40 feet wide, and the boiler house is 100 feet long × 54 feet wide. We may emphatically state that we have seldom inspected any electricity works in this country that are better designed than those at Plymouth; the engine room is unusually lofty, the machinery is not cramped in any way,



General View of Engine Room.

and the switchboard arrangements have been exceedingly well thought out. Moreover, the office portion has been designed in no niggardly spirit, the staff being well provided for both in the way of office and mess accommodation.

The steam raising plant at the present moment in use, for which Messrs. Musgrave & Sons, Ltd., are responsible, comprises three Lancashire boilers, each of which will develop steam for 350 I.H.P. They are 30 feet long and 7 feet 6 inches in diameter, and have each 3 feet furnaces. Vicars' mechanical stokers are fitted to each boiler, and are driven by means of an electric motor, the same motor being also employed for driving the Green's economiser. As we have already indicated, the coal is fed from the store, which is carried over the length and breadth of the stoking floor. The water is fed to the boilers by means of Hayward Tyler's three-throw ram pumps, which are driven by electric motors. These pumps draw water from a storage tank, which is placed on the top of the coal store, having a capacity of 28,000 gallons of

Digitized by Google

water. It may been mentioned that over the coal store two tanks have been erected, one for the condensing water, and the other for the boiler feed water. Each tank measures 80 feet long by 25 feet wide, and is about 7 feet deep inside. They are built up of cast-iron flanged plates, and access to the tank floor is obtained by means of a ladder leading from the coal store. In addition to the three pumps there is also provided a Gresham's self-acting injector which is capable of delivering 4,400 gallons of water per hour, against a steam pressure of 130 lbs. per square inch. An economiser consisting of 256 pipes arranged in two blocks, each eight pipes wide, has been provided, and is of the latest type, complete with deflectors, scrapers, and gearing. The steam piping is exceedingly well arranged and is probably one of the most interesting features of the works. It is of lap-welded wrought-steel with wrought-iron flanges secured and brazed on, the bends being of solid drawn copper with flanges of the same material brazed on. The piping is so arranged that while, generally speaking, each boiler feeds its own engine, it is possible to cut out any boiler and obtain steam from the others. This arrangement is carried out by means of an auxiliary main passing along the back of the boilers with a T junction to each of the mains from the boiler to its engine. It is evident, from an inspection, that the design permits of a short length of pipe, and, moreover, gives the necessary duplication. Hopkinson fittings are used throughout the steam piping. Korting ejector condensers are employed and are placed under the engine house. The condensing water is carried from the Cattewater through the inlet pipe, which is pushed forward into the stream, and from thence passes under the roadway in a trench. There are three centrifugal pumps of the Gwynne type having 6-inch suction and discharge pipes. They are driven by motors of the Electric Construction Company's manufacture. The whole steam, exhaust and other pipes are covered by magnesia non-conducting material, and an arrangement has been adopted which materially adds to the appearance of the boiler house, and may possibly affect the efficiency to some extent. The whole of the boilers and the top of the economiser are covered by a floor upon which is laid magnesia covering to a depth of about 3 inches; this undoubtedly permits of easy inspection and operation of fittings and valves, and guards to some extent against radiation losses.

Car on Line.

Coming now to the engine room plant, the machines that merit first consideration are the combined plants. They have been termed steam dynamo alternators, and as will be seen from the illustrations, they consist of an engine driving an alternator and a continuous current dynamo arranged in line on a shaft, the whole of the plant being upon a combination or coupled bed-plate. There are two of these sets; the steam engines are made by Messrs. Belliss and Co., of the enclosed vertical type to run with two cylinders arranged for compound working, and capable of giving off continuously 150 B.H.P. The alternator is placed between the engine and the continuous current machine, and the functions performed by these machines render necessary a special arrangement of clutching devices. Mr. Rider, in advising this combination, has had in mind a combination of arrangements which he suggested some time ago, viz. :—

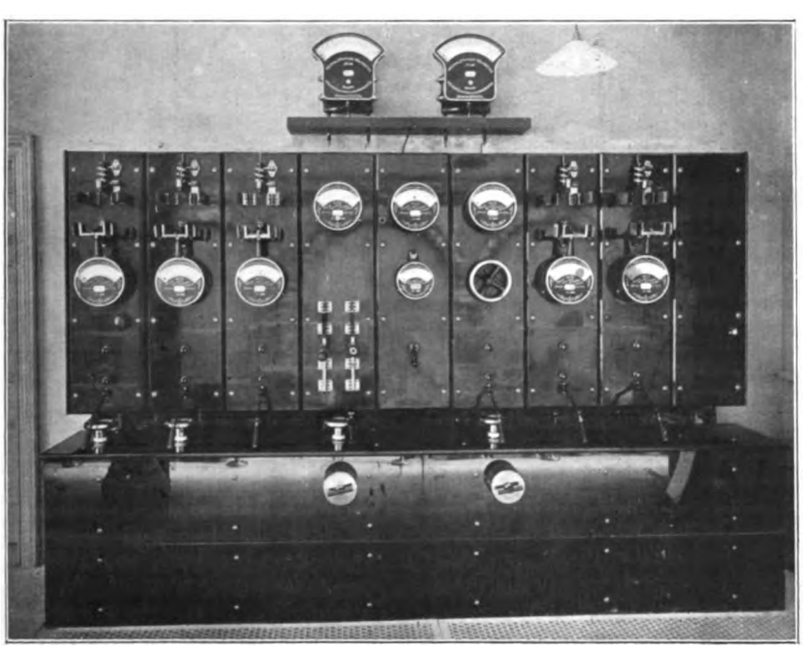
(*a*) Engine driving both alternator and dynamo, one for lighting and the other for traction.

(*b*) Using the plant for tramway work alone; that is, the alternator being uncoupled.

(*c*) For lighting work only, the continuous current dynamo being uncoupled.

(*d*) The engine being uncoupled, and the machine running as motor-generator for traction, the current in this case being obtained from bus bars to work the alternator as a motor.

(*e*) Engine uncoupled, machine running as motor-generator for lighting, in this case the continuous current machine is driven by the accumulators.

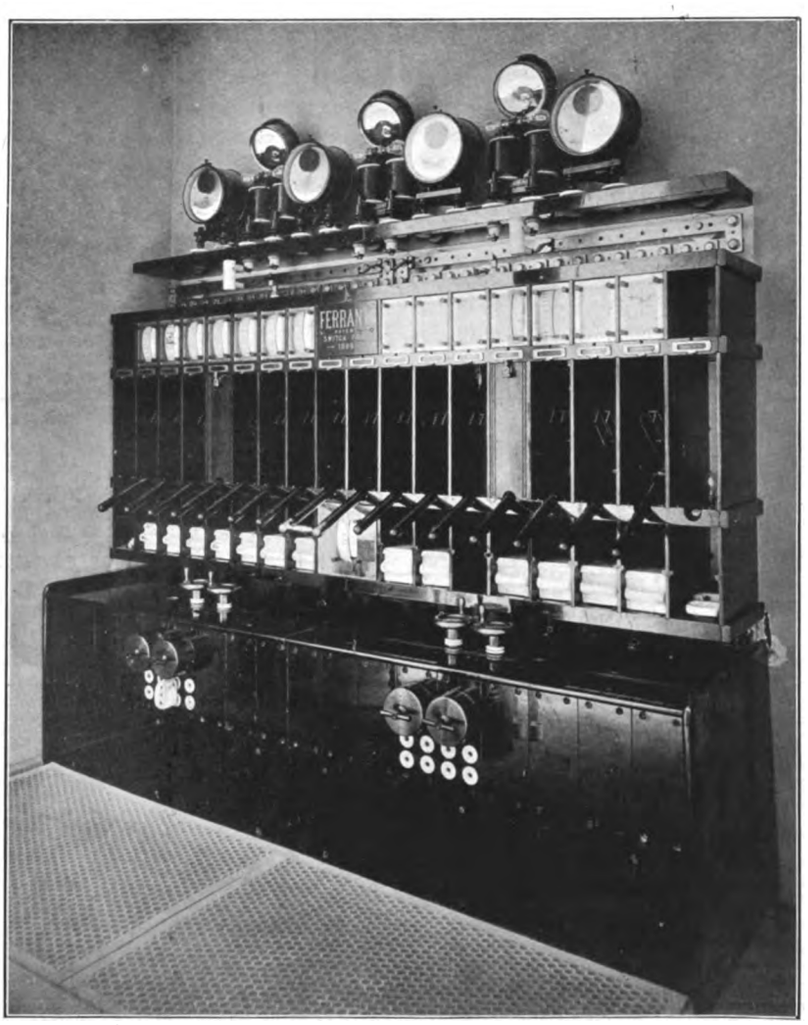


Traction Switchboard.

A consideration of these will show the great variety of functions that can be carried out by this plant. It may be said, however, that the success of the arrangement depends entirely upon the clutching devices, for the question of efficiency when the engine is driving only one machine can be left out of account. The type of clutch adopted is of the Lindsay coil pattern, and may be said to be a steel spring held at one end and coiled round a chilled iron sleeve, the other end being free and twisted over. To meet any

Digitized by Google

irregularities of drive, the clutch is made double, and each part will work in either direction, so that in the event of one portion of the combination running somewhat out of step one-half of the clutch would be always working right. When using this plant as a motor the usual method is to run the engine up to speed, and when the dynamo is excited the engine can be thrown out of gear. The alternator in this combination plant is of the well-known Ferranti pattern, while the continuous current machine is of the Westinghouse railway generator type. It is of multipolar pattern, and consists of a circular yoke carrying inwardly projecting pole pieces of laminated soft steel. The fields are split horizontally, which permits of ready inspection of armature or field coils. These generators are usually built over-compounded, so that the potential at the terminals increases about 10 per cent. from no load to full load. The shunt and series coils are separately wound and readily removed, the series coils being composed of forged copper conductors of rectangular section. The armature core is made up of punched sheets of steel. This core is built upon an iron spider, which also carries a commutator. The spider is pressed and keyed upon the engine shaft, and may be drawn off at will. Ventilating spaces through the spider and armature cores are so arranged as to allow a constant circulation of air through the commutator and windings when the machine is running. The periphery is slotted and the armature windings are made from bars of drawn copper forged into proper shape on cast-iron formers. After being thus shaped, the bars are thoroughly insulated with mica and prepared and baked to remove moisture. The coils are held in the slots by means of retaining wedges of hard fibre driven into notches near the top of the slots longitudinally with the armature. These fibre wedges are pressed out at will should it be necessary to remove any armature coil. The commutators are of hard-drawn copper, the segments being built up with prepared mica of corresponding hardness. The brush holders are carried on brackets projecting from a ring concentric with and supported by the field. A hand-wheel rocker arrangement gives the necessary adjustment.



Lighting Switchboard.

The other generating plant in the station consists of steam direct-driven alternators. Both the engines and alternators have been constructed by Messrs. Ferranti, and each set is capable of developing 200 KW. The engines are of the compound condensing type, and each set is built on a special foundation bed. The fly-wheel is placed between the cylinders, and carries the revolving part of the alternator. The working parts of the engine are accessible, but when working are enclosed; the lubrication is effected entirely by force pumps which draw oil from reservoirs and deliver it under pressure to the various bearing surfaces. For street lighting there are three Ferranti rectifiers of the latest type. The generating plant is completed by a motor-generator capable of developing 150 amperes at 133 volts, the motor being supplied with current at about 500 volts pressure. There are three switchboards, two of which, the lighting and tramway boards, are arranged in a special gallery, while one, the rectifier board, is placed on the engine room level. The lighting board is of the well-known Ferranti pattern which has been often described in these columns. A few feet away, on the same gallery, is the tramway board which is supplied and equipped by the Westinghouse Company. The principle of this board does not differ materially from those usually employed in tramway works. It is divided into panels for feeders and for the Board of Trade instruments.

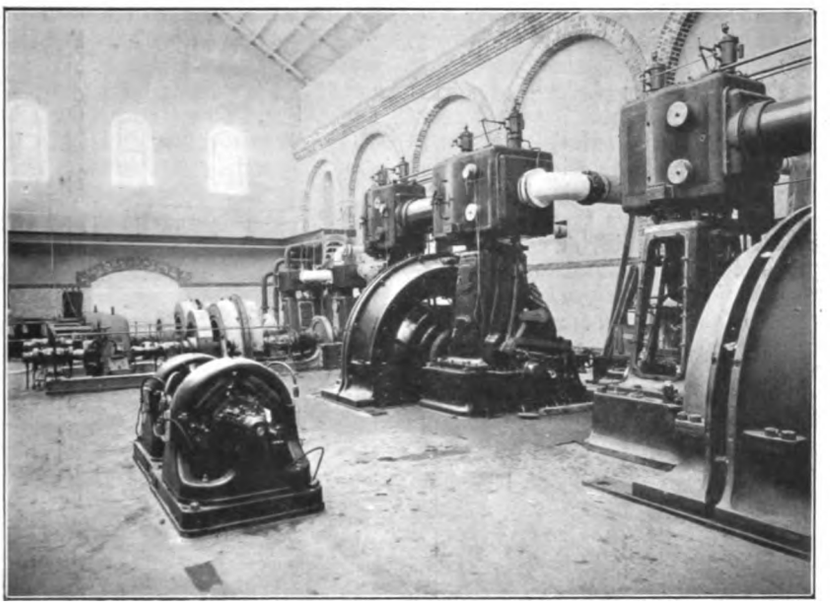
The battery consists of 260 cells, supplied by the Tudor Company; the capacity of each cell is 620 amperc-hours at 120 amperes, with a maximum discharge rate of 200 amperes.

The outside work divides itself into two portions, the street lighting and the tramways. Before speaking of this, however, we would point out that the distribution of electricity for private lighting is done by means of transformers placed in chambers built under the footpaths in different parts of the town, access to these being obtained by means of an iron ladder. As a rule four 25-KW. transformers, transforming down from 2,000 to 200 volts, are placed in each chamber. The transformers have been constructed by the Ediswan Company, and of those supplied eight are for 25 KW., each weighing over 1 ton. The terminal fittings of these are mounted on separate porcelain slabs, the secondary connection being arranged for use on a three-wire system, so that 200 or 100 volts can be obtained. The sweating sockets are specially designed and arranged to pass readily through the glands, and are no larger in diameter than the insulated cable. Other types of Ediswan transformer have been furnished, one in particular being for 1,000 volts and 2 amperes. Another has been supplied for meter testing, and is arranged with a secondary sub-divided in such a way that any pressure between 90 and 200 volts can be readily obtained. The whole of the mains have been made by the British Insulated Wire Company, but all the work in connection with the laying has been carried out by the Corporation under the direct supervision of Mr. Rider. The high tension mains are composed of $\frac{7}{14}$ and $\frac{19}{15}$ concentric, which are insulated with paper, lead covered and juted, and compounded over the lead, drawn into Doulton earthenware conduits. The low tension cables are

Digitized by Google

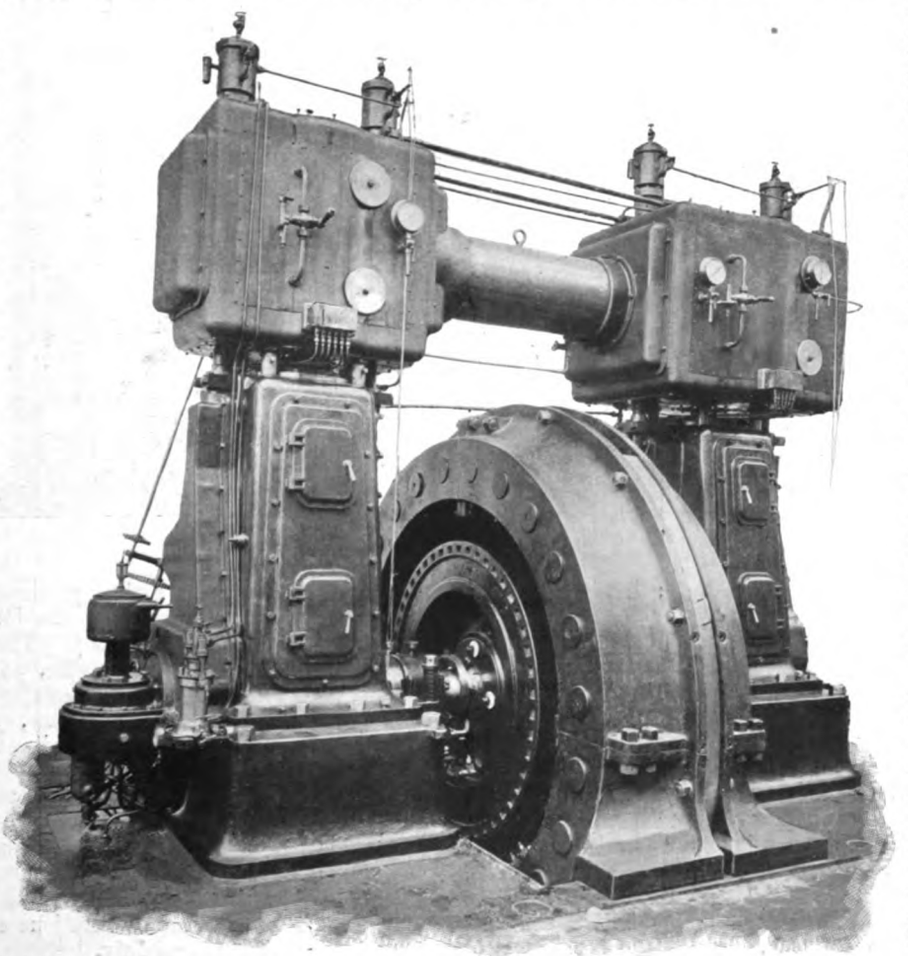
·150-inch, ·20-inch, and ·250-inch triple concentric. These are armoured, and have been laid direct without further protection, as was also the tramway feeder, which is composed of ·150-inch single cable.

The arc lighting cable consists of $\frac{7}{16}$ S.W.G. twin paper insulated lead-covered and armoured, laid direct in the same way as the triple cable, single rubber cables being used between the arc service boxes and the lamps themselves. It is worth mentioning that the service boxes of the arc lamps where they are suspended to the tramway poles, are placed under the foot-path instead of being fixed under the base of the lamp column.



View of Engine Room.

The house service cables are generally composed of $\frac{19}{14}$ and $\frac{19}{16}$. These are concentric and laid direct, the service being connected by means of triple concentric service boxes, with wiped glands, the service terminals being connected by means of fuses to the main terminals. It will be readily understood from what has been said that arc lighting forms a conspicuous feature in the scheme which has been completed. As a matter of fact, there are at the present moment some 74 lamps erected, 13 of which are on the Hoe. As far as possible tramway poles have been utilised, but where the arc lighting is carried out in streets where tramways do not exist, separate poles of a special design are employed. A word of praise ought to be awarded to the designer of the scroll work carried on the top of the poles, and it is gratifying to find that the designs have been originated in the borough electrical engineer's office, Mr. E. G. O'Kell, the chief assistant engineer to Mr. Rider, being responsible for them.



Single Alternating Set.

The pillars are of two kinds—(*a*) cast-iron throughout, and (*b*) tubular steel, with cast-iron mountings. There are 48 cast-iron posts and 30 tubular posts; 28 of the lamps are suspended from wrought and cast-iron brackets, and 50 are fixed in ornamental canopies. The tubular posts are also used for carrying the span wires for the tramway overhead conductors.

The lamps are of the well-known Crompton-Pochin type. They are arranged to burn with a rectified current of 10 amperes. They are double carbon and burn for not less than 32 hours without re-trimming. Each lamp is provided with an internal automatic cut-out to short circuit the lamp in the event of any accident to the mechanism. Each lamp is also provided with an isolating switch, which enables the lamp to be entirely disconnected from the mains and the two cables leading into the post to be connected together. With this arrangement it is possible to re-trim a lamp while the current is on, without any danger to the attendant and without in any way interfering with the remainder of the circuit. In the case of the cast-iron posts, these switches are fixed in the base. In the case of the tubular posts the switches are in water-tight cast-iron boxes under the pavement.

The lamps are run in two circuits off Ferranti rectifiers, each rectifier being capable of supplying current to a circuit of 50 lamps in series.

The whole of the street lighting work, including the erection of the lamps, poles, &c., and the coupling up, has been carried out by Messrs. Crompton & Co., Ltd., of Chelmsford and London.

It is necessary now to refer to the tramway portion of the undertaking, and though the work for the most part is similar in character to the work carried out on other systems, still there are details which might be referred to with advantage. The track which has been specially constructed for electrical operations extends from the Prince Rock to the Royal Theatre in the centre of the town. The line is double throughout and has a gauge of 3 feet 6 inches, the rails being of the girder type, and weighing 92 lbs. per yard.

Digitized by Google

They are heavily bonded together, three Chicago bonds being employed in place of the two usually adopted. Messrs. Askham Bros. & Wilson, Limited, supplied a quantity of material in the shape of their patent crucible cast-steel points and crossings, together with their patent joint plates with lock nuts. Mr. Rider is a believer in the swivelling trolley, and it is interesting to observe how he has utilised the undoubted advantages of a revolving trolley head in arranging the overhead wires. Practically every form of overhead suspension is employed, side suspension from single arm brackets, centre poles, suspension from buildings, and suspension from posts and buildings. But a method is employed which we believe has not been previously adopted in this country, it is the suspension of wires on each side of the road. Obviously this is more expensive than employing single arm brackets, it being understood, of course, that central poles are not permissible, but the advantage of a wire being carried on each side of the road is that it needs short arm brackets. It will be seen from the photographs that this method has much to commend it, and is unquestionably an improvement upon the long arm brackets, which are becoming so marked and disagreeable a feature of much of the overhead construction at present in vogue. The wire is of 000 gauge, guard wires being employed practically throughout the system. The tramway poles are of two kinds—they are all of cast-steel; but while some are made in three sections, others have been made in a single section. The engineer, in specifying for the posts, insisted upon an exceedingly rigid test; they were to withstand being dropped three times (butt end foremost) from a height of 6 feet on to a solid substance, and as a bending test they were laid horizontally from a support 5 feet 6 inches from the butt end, and loaded at a distance of 18 inches from the top end with a weight of 700 lbs. The temporary deflection was not to exceed 6 inches. The line is divided into half-mile sections, a junction box being placed at each half mile. Instead, however, of taking the form of a pillar placed at the edge of the kerb, Mr. Rider has adopted a plan which is worth noting; the box, as a matter of fact, is sunk into the wall. The door of the box is flush with the service wall, and looks not unlike a safe. It should be mentioned, however, that both section boxes are on Corporation property, and it is doubtful whether private owners would generally permit of a box being sunk into their property. The rolling stock is not very extensive at present, and consists of only six cars, each of which will carry 42 passengers, 20 inside and 22 outside. The bodies have been constructed by Messrs. Milnes & Co., and are carried on Peckham cantilever trucks. Westinghouse equipment is used on the cars; there are two motors, and the usual controlling devices—emergency switches, electric brakes, &c. The electric braking arrangements are similar to those employed on other lines using Westinghouse equipment. For braking purposes the motors work on a closed circuit, which is varied gradually, the operation, of course, being independent of current from the trolley line. The cars are lighted with electricity in the usual way. Our thanks are due to Mr. J. H. Rider for the courtesy shown to our representative on the occasion of his visit.

Plymouth.—Street Scenes.

2,000-H.P. ENGINES.

The largest factory engines ever made were constructed, we believe, for a Bombay cotton mill by Messrs. Hick Hargreaves and Co., of Bolton. They were of some 4,000 H.P. Marine engines of 30,000 H.P. have been made for Atlantic liners, but, unless the increase has been recent, the maximum power put through any one crank is 5,000, and this figure was reached many years ago in the *Britannic*. In the early days of electricity there was a tendency towards over confidence. This tendency was exhibited by the intention to put down a 10,000-H P. engine at Deptford. The engine, to use an Americanism, did not materialise, at least, not wholly, though a very large shaft was on sale at Deptford. A pair of 1,500-H.P. engines were, for a time, spoken of as the little engines in pleasing anticipation of joys to come in the shape of the large engine which never came. The attempt to do too much at once, to take too big a step, has probably had much to do with the niggling manner in which the steam engineering of central stations has since been carried on. The fact that 10,000-H P. engines failed to be completed, was probably due to a financial, not an engineering, cause, and was no warrant for other stations employing a hundred little engines on the same duty.

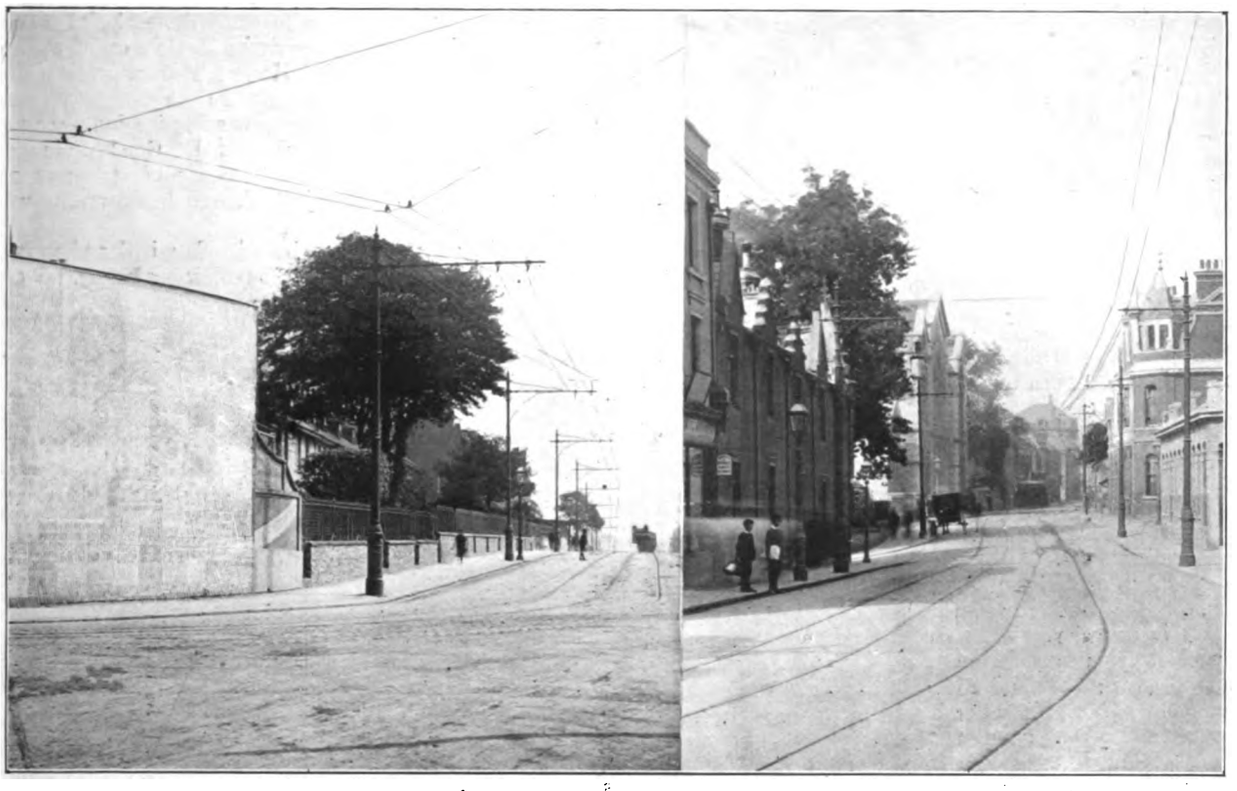
Since the days of big things, however, Deptford has gone steadily, and the new engines called for some time ago have been some months at work, and are now described in the *Engineer*, from which we gather a few of the principal dimensions and figures. Made by Messrs. Plenty & Son, Limited, of Newbury, they are of 2,000 H.P., with three

Digitized by Google

cranks and six cylinders in vertical tandem pairs. The engines are by no means of large size though of a considerable collective power. The high pressure cylinders are 19½ inches diameter, the low pressure cylinders are 43 inches, and the stroke is 26 inches. The speed is 156 revolutions per minute, and the initial pressure 140 lbs. The Siemens-Martin steel shaft is 12 inches diameter in both main bearings and crank pins. The valves of each pair of cylinders are worked by one eccentric, the high pressure valves being of piston type and the low pressure valves of flat or D type. The details are not clearly shown, but seem to indicate too small a valve chest to the low pressure cylinder and somewhat cramped valves. The marine type has generally been followed except that they exhaust to independent condensing plant. The generator driven by these engines is a direct coupled Ferranti alternator, having an output of 150 amperes at 10,000 volts. A test load of 300 amperes has been run and 15,000 volts have been put on the insulation generally, though some of the details were put to more severe tests; for instance, the pole caps of micanite have been tested to 21,000, these magnet pole caps having been the chief offenders years ago in the early failures of 10,000-volt machines.

The *Engineer* states that the latest Deptford machine was finished one day, tested for pressure the next day, for current the third day, and on the fourth day was put on the mains at 10,700 volts at a load of 125 to 140 amperes, and has so been at work half a year. Why, therefore, should other companies go to America for 500-volt plant and costly upstep transformers, when they might manufacture the full pressure at once? At Deptford the "low pressure" plant at 2,500 volts is to be scrapped. The armature, which weighs 38 tons, has 64 bobbins, with cores of laminated brass and asbestos. They are bolted to the wheel with the above-named micanite cap insulation. They are wound with copper corrugated tape, and insulated with silk and vulcanised fibre. Pump lubrication at 15 to 20 lbs. pressure is carried throughout the shaft bearings. The armature shaft is coupled to the engine shaft, and the bedplates are connected into one rigid whole. Current is collected by three brushes from a split ring fixed on the wheel, on the side away from the engines. The field magnets number 128, one on each side of the armature bobbins. Their pitch circle is 20 feet diameter, and the peripheral speed is over 10,000 feet per minute. The field coils are of solid rectangular copper strip. A good deal is made of the three cranks, and five are prophesied. Now three cranks are convenient, but even in a three-crank engine, arranged as at Deptford, all the work has to go through one main bearing, and two of the cranks are too large for their work. In a five-crank engine, probably three of the cranks will be too large, if not four, and an extension in the line indicated is of doubtful value and very problematical economy.

The engines illustrated by our contemporary are open to some criticism. It is extremely bad practice to make the H.P. piston, or, indeed, any piston of a vertical engine with a recessed water-holding upper side. Perhaps we ought to forgive the conical form, though this is avoidable, but if the piston must be conical, it should cone from the cylinder, and not be made water-holding. Then the exposed inner surface of cylinder and cover and piston is enormous. The H.P. piston rod is shown fluted circumferentially, so that it closely resembles a square-threaded screw. Between the two cylinders there is no stuffing box but merely a long sleeve through which works the fluted rod. No explanation of this is afforded though the idea appears good. The cylinders are well drained at their lower ends, but as above stated, are badly provided with drainage above the pistons. The bracket carrying the rocking lever of the high pressure valves is shown as one piece with the top cover of the high pressure valve chest. This is hardly good practice, either for the valve motion pins and bearings, already numerous enough, or for the faced joint of the valve chest cover, which, however, it is only fair to say, covers the exhaust end of the chest.



PLYMOUTH.—STREET SCENES.

ELECTRIC TRAMWAY SYSTEMS AND FREIGHT DISTRIBUTION.

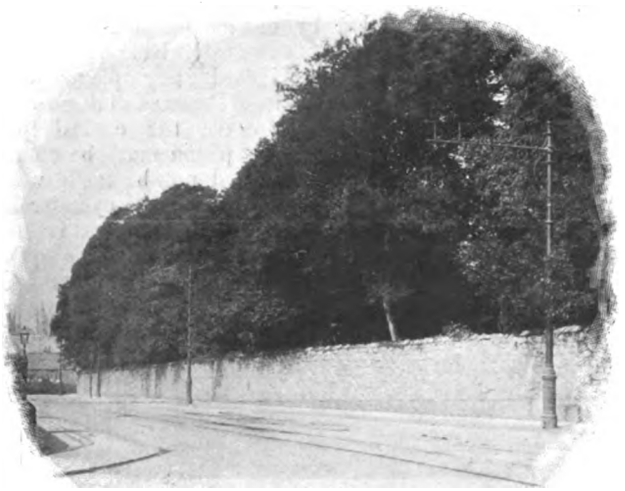
IN a recent issue (see ELECTRICAL REVIEW for June 9th) we referred to the use of the tramway system in Brooklyn for freight purposes, and we discussed the future prospects of this development of electric traction. Since that date we have come across two facts of interest in connection with this subject.

In the issue of an esteemed contemporary for March 18th last, there is a description of a specially designed meat-car for

Digitized by Google

use upon the electric tram system of Buenos Ayres—a city of 850,000 inhabitants.

Owing to the excessive heat, a rapid distribution of the meat killed at the public abattoirs is most desirable. The



Plymouth.—Street Scene.

municipal authorities have therefore taken the matter in hand, and have arranged with the tramway company for a special service of these meat-trolley-cars, to be run between the hours of two and nine in the morning for conveyance of the meat from the abattoirs to the various retail establishments of the city.

The second fact relates to the suggestion, made in our last note on this subject, to the effect that a cart or car which could be run either on the ordinary road, or on the tramlines, was required, before the electric tramway system could be widely utilised for freight distribution during the early morning hours.

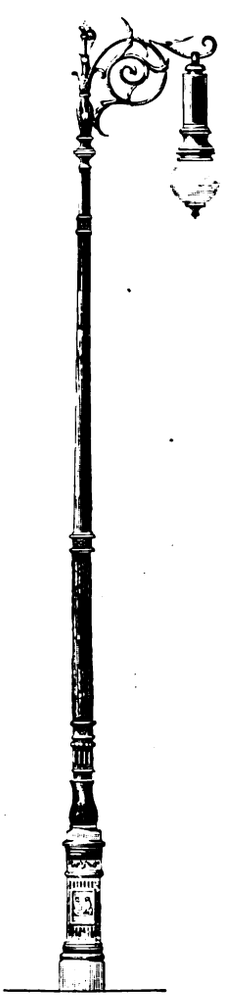
A car has been designed by Messrs. Siemens & Halske, of Berlin, for use on either the ordinary roads or on the tramway lines within that city. When running on the ordinary road, it is worked by an electric motor, and draws its power from a storage battery; when on the tramway lines the motor is driven from the overhead conductor by means of a trolley apparatus, and is kept upon the track by means of two pairs of guide wheels, which can be raised and lowered at will. The storage batteries can be re-charged when the car is running on the tramlines by means of a second trolley pole and apparatus.

This car is intended only for passengers, and it has been successfully run in the streets of Berlin, but it is evident that the utilisation of such cars could be widely extended, and that *if economical in operation* they might be used to distribute every kind of freight and merchandise within the area of the larger towns and cities.

ARRANGEMENTS OF STEAM PIPES.

Mr. Edgcome's paper on steam pipes, read before the Municipal Electrical Association and reprinted on another page in this issue, is written from the point of view of a man who believes in ring mains. To our mind the ring main is a contrivance for providing for breakdowns which would not occur if there were no ring main. As we reproduce the paper in order to let the views of the ring main have fair treatment, it will be seen what a lot of complicated drainage the author thinks necessary to provide. He would have a station full of steam traps and drain pipes. We do not follow the author's reasoning as to the isolating valve and its functions. This valve does not enable a boiler to recover itself in the manner described, but it does prevent a boiler from acting as a condenser, and from swallowing up steam from more active boilers, and it is an admirable safeguard when men are at work inside a laid-off boiler, for it prevents the disastrous effects which follow the accidental opening of the junction valve whereby men may be injured. We rather object to his remarks anent the use of safety keys for blow-out taps. The keys he describes are excellent as a preventive against accidental leaving open of a blow-out tap, for the key cannot be removed until the tap is closed. So far, good. But there is always the chance of there being duplicate keys. Spare keys may be kept under lock and key, but some day a second key will get into the boiler room. Perhaps one key is lost. A second is procured. The first is found again. There are now two keys, and this is sure to be the moment selected for a man to be coming out of an empty boiler. A working boiler is blown off into the common waste pipe, and the man in the empty boiler or half out of the mud-hole is endangered. The lesson is, avoid common waste pipes. Carry each boiler blow-out by its separate waste pipe, so that there cannot be a back flux; but do not trust to special keys except as a safeguard against a collapsed furnace, for which they are admirable. The author points out the danger, but considers locking up of the spare keys is sufficient safeguard. He is mistaken. He is wrong in advising the making of stringent rules against other usages which ought not to be capable of causing the dangers against which the stringent rules are needed. Good design of a boiler plant should avoid the necessity of stringent rules which are always forgotten just when their observance would lead to safety.

If Mr. Edgcome had ever been inside a boiler when it had been blown into from a common blow-out waste, he would



Plymouth.—Lamp-post.

have had less to say of stringent rules, and more to say of the faults which render such rules necessary. The common waste pipe is one of these faults. It may be usual practice. This does not justify it.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

(*Continued from page 232.*)

Middleton.—Last week the Council passed a resolution to make application to the Board of Trade for powers to construct tramways from Middleton to the Manchester boundary. Middleton is laying the lines, but the service will be supplied by the Manchester Corporation, with whom an understanding has been arrived at. It was also decided to make application to the Local Government Board for borrowing powers for a further sum of £4,500 for electric lighting purposes.

Newcastle.—At a meeting of the Tramways Committee on August 1st, it was reported that Prof. Kennedy was not prepared to recommend the laying down of a conduit or any intermediate service in the city in connection with the overhead trolleys from outside, but preferred to await developments. There was a suggestion, however, that centre poles be fixed throughout the main streets, as a temporary arrangement, and when practical experience showed a better system these could be removed. It was agreed to recommend the Council to instruct the engineer to advertise for tenders for rails for the permanent way, boilers for the power station, &c., in order that that portion of the work might be proceeded with.

Oldham.—The Surveyor's and Tramways Committee's chairman, Ald. Eckersley, the surveyor (Mr. Pickering), and the electrical engineer (Mr. Newington), recently had an interview with Mr. Alderman Higginbottom, of Manchester, regarding the tramways. Reports respecting the interview were read at a meeting of the committee on Thursday last week. Mr. Pickering said that Alderman Higginbottom did not believe in calling in experts. He did not see why Oldham should not do the same as Manchester, and rely upon its own electrical engineers. He expressed the hope that his Corporation would eventually come to a reciprocity agreement with Oldham for the through service of cars between Manchester and Oldham. Alderman Eckersley's report states that, after the interview, he (Ald. Eckersley) was of opinion that the committee had decided to recommend to the Council the system best adapted to Oldham, and he was more decidedly so when they took into account that they would be more thoroughly able to work their own system in conjunction with Manchester and Rochdale by agreement, as he hoped, to the mutual advantage of all three municipalities. Mr. Higginbottom gave an invitation to visit the Manchester Electricity Works, and he (Alderman Eckersley) thought much good might result to the committee by doing so, and to the Electrical Committee also. He hoped now that the committee would bend its energies to the carrying on and completion of this great scheme.

Peking.—The *Westminster Gazette* learns from the *North China Daily News* that the first electric tramway in China was opened on Saturday, June 24th, between the Peking station at Machiapu and the south gate of the metropolis Yung ting-men. The whole system works excellently. The tramway was projected and constructed by Messrs. Siemens & Halske, of Berlin. It is intended to extend the tramway inside the city, a great difficulty being to break a new gate for the line through the city walls; but after all it will only be a question of time, it being an urgent necessity to have a better communication between the Peking station and the city. "Why should London wait?" asks our green contemporary, forgetting that its own party on the London County Council has been responsible for the delay in London.

Portsmouth.—At a meeting of the Town Council, on August 8th, the Tramways Committee submitted the names of three candidates for the post of superintendent of the reconstruction of the tramways, viz, Messrs. Alan Bannister, of Norwich; E. Rotters, of Seton, Kerr & Co., and F. Smith, of Coventry. The recommendation of the committee that Mr. Bannister be appointed at a salary of £400 per annum, rising to £500, was unanimously adopted. The committee was authorised to invite tenders and to obtain such assistance as might be necessary for carrying out the work.

Rotherham.—The Town Council has appointed a Parliamentary Committee to consider and report on a proposed omnibus bill, dealing with, amongst other matters, a scheme of electric traction.

Stockton.—At a meeting of the Tramways Committee of the Corporation, held last week, Mr. J. Clifton Robinson announced that the Imperial Tramways Company had decided to abandon the extension of the Teeside system to Eaglescliffe for various reasons, the chief being that the requirements of the local authorities were of a too exacting nature.

Stretford.—A meeting of the Electric Lighting and Tramways Committee was held on the 25th ult., at which a letter was read from the United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited, requesting permission to open negotiations with the Council with a view to the construction of a light railway through the township as part of a scheme comprising the districts of Urmston, Eccles, Farnworth, Radcliffe, and Prestwich. The company asked for a concession of 42 years, and offered to equally divide all profits after they had realised 7½ per cent. The committee resolved that they were unable at present to entertain the proposal. At the same meeting a letter was read from Messrs. Crofton, Craven & Worthington, intimating that the Manchester Ship Canal Company had given notice to the Board of Trade objecting to their granting an extension of time for the construction of the Trafford Road line. The committee resolved that the Manchester Carriage and Tramways Company be requested to at once construct, in a manner suitable for electric traction, that portion of the tramline in Trafford Road authorised by the company's provisional order of 1897. The minutes were adopted. Mr. Robinson stated the position of the Council with regard to the Port Sanitary Authority. In a scheme which it had put forward, the Authority sought to make each district protected liable to pay the expenses properly chargeable to it. The scheme was only tentative, but its reasonableness was admitted. An inquiry was to be held by the Local Government Board, the result of which would be to confirm the arrangements made, and to renew the order for a further period.

West Bromwich.—The Council has decided to promote a Bill in Parliament to purchase, maintain, work or lease that portion of the South Staffordshire tramway which is within the borough. The object of the step is chiefly to strengthen the position of the Council in negotiations with the Tramway Company.

West Hartlepool.—The British Electric Traction Company has given notice of its intention to proceed with the light railway from Church Street to Seaton Carew.

Wolverhampton.—The Lighting Committee has concluded an agreement with Messrs. Chubb & Sons, for the supply of electricity to their factory at 4d. per unit for lighting and 1½d. per unit for motive power for a term of five years.

TELEGRAPH AND TELEPHONE NOTES.

The "All-British" Cables.—A Melbourne telegram, dated the 4th current, says that Mr. Duffy, Postmaster-General of Victoria, has given notice that he will move that it is expedient for Victoria to join Great Britain, Canada, New South Wales, Queensland and New Zealand in the construction and working of a Pacific cable touching British territory only.

An electrical contemporary, in referring to the cables which the Eastern group of companies propose to lay from the Cape to Australia, says: "As the West African route is not a strong one and is more or less at the mercy of the French Colonies, while the East Coast cable goes, of course, to the Mediterranean, like the rest, the proposal will hardly commend itself as a substitute for the Pacific cable."

In the House of Commons, on Monday last, Mr. Hogan asked the Secretary for the Colonies whether he had received any further information in reference to the settlement of the remaining points at issue in connection with the construction of the Pacific cable; and whether the negotiations had now sufficiently advanced to enable him to give a general outline of the amended scheme of joint ownership and mutual responsibility, as agreed upon by the representatives of Her Majesty's Government and the Colonial Governments concerned.—Mr. Chamberlain replied: The terms of the arrangement are not yet completely settled, and I am not in a position to make any statement.

A writer in the *Moniteur Universel*, in reference to the Pacific cable, says that the matter is one of life or death to the French possessions in the Pacific. He calls on France to come to an agreement with the United States for the laying of a cable from San Francisco to New Caledonia, with a view to forestalling the British project, being of opinion that were this done the proposal for a Canadian cable would be abandoned.

The City Police and the Telephone.—After an extraordinary amount of delay, says the *City Press*, the headquarters of the City police force have been connected with the National Telephone Company's system.

Hull Telephones.—At the last Council meeting a motion was considered for giving notice to the National Telephone Company to terminate the agreement as to the wayleaves in the city. A deputation attended, consisting of Sir Albert Rollit, M.P., Alderman Franklin, of Sheffield, and the general manager of the Telephone Company. Alderman Sir J. T. Woodhouse, M.P., said this was a very serious matter, not only for Hull but for the National Telephone Company. The Bill now before the House of Lords was on the point of being passed, and it was essential that they should place themselves in a safe position by giving the Telephone Company notice. Alderman Larard then reviewed the steps taken by the National Telephone Company in connection with the bill now before Parliament. If it passed they would be placed in a very serious position unless they gave the notice which he had placed upon the paper. If the bill passed as it stood, and it was very likely so to pass, then they would lose control to some extent of their streets until 1911. That was a state of things the Council ought to resist, and he therefore gave notice of motion that the agreement as to wayleaves with the National Telephone Company should be terminated in six months. He moved his resolution with the hope that it would be unanimously carried. Mr. Gane, the general manager of the National Telephone Company, stated that the Corporation could, according to the agreement, terminate it on giving six months' notice, and the position of the Council would never be affected unless they determined to become competitors with the National Telephone Company. That company was spending thousands of pounds in Hull, and they had recently entered into a contract to spend more thousands, but if the resolution was passed they as a company would not spend another

Digitized by Google

farthing with a risk of confiscation of their property. The question was, was the Council prepared to put an end, as it were, to the telephone service in Hull, or at any rate to very seriously injure that service? As he had said, there was nothing in the agreement to affect the Corporation unless it determined to take over the telephones, and he hoped the Council would not in haste damage the telephone service in the city. The deputation then retired, and Alderman Sir James Woodhouse spoke strongly in favour of the motions, which were carried, with one dissentient.

Melbourne Telephones.—The *British Australasian* says that it is now fairly certain that the Postal Department will decline to comply with the request of the Ballarat sharebrokers for the erection of private telephone lines between Melbourne and Ballarat. It is likely that additional public lines to Ballarat and Geelong will be started shortly, also one to Bendigo.

Norwich and Yarmouth Telephone Service.—In the House of Commons on Friday, the 4th inst., Sir Harry Bullard, one of the Conservative members for Norwich, put the following question to the Secretary to the Treasury, as representing the Postmaster-General, "whether he is aware that serious inconvenience is occasioned in consequence of the insufficient trunk line telephone communication between Norwich and Great Yarmouth, and whether he will take steps to remedy the same." Mr. Hanbury, in reply, said that an additional circuit between those places was opened in March last, and at present more than 50 per cent. of the calls were effected within five minutes. The electrical working of the wires was satisfactory. The traffic, however, was growing, and the Postmaster-General had at present under consideration the provision of additional facilities.

Questions in Parliament Regarding Various Cables.—On Friday, the 4th, on the report of the vote to complete the sum of £71,241 for the subsidies to certain telegraph companies, Sir C. Dilke said it had been strongly rumoured lately that the companies subsidised in this vote were making an alternative route. He would like to know whether the Government could give them similar information to that laid before the Cape Parliament on the subject of the working of the lines subsidised in this vote, of the proposal for an alternative line to the Cape, of the opinions of the home Government as to the strategic importance of the proposed line, and whether, owing to the recent increase of trade in South Africa, these subsidies were necessary. He also wished to know whether the Chancellor of the Exchequer could tell them anything about the recent delays in Government messages from the Cape.

The Chancellor of the Exchequer said there had been proposals under the consideration of the Government from the telegraph companies for a new cable between this country and the Cape, touching St. Helena and Ascension. Negotiations had also been in progress between the companies and the Government of the Cape as to a considerable reduction in rates in return for a grant of land rights. He could not say the matter had approached completion, nor how far papers could be presented. But there were proposals before them which were considered of considerable strategical importance by the Admiralty as to the proposed new communications. With regard to the undue delay of Government messages from the Transvaal, he knew nothing about it, except that there was a breakdown. He knew of no other cause.

The report of the vote was agreed to.

On Monday last, in reference to the proposed cable from South Africa to Australia, Mr. Hogan asked the Secretary for the Colonies what response, if any, had been received from the Colonial Governments concerned to the offer of the Eastern Extension Company to construct a cable from South Africa to Australia.

Mr. Chamberlain said the offer in question was not made through this department. I have no information as to any replies that may have been given to the company by the Colonial Governments concerned.

On Tuesday last the following questions were asked concerning international telegrams:—Sir C. Dilke asked the Secretary of State for India whether it were possible to lay before Parliament any agreements and correspondence between the Government of India on the one side, the Eastern Telegraph Company, the Indo-European Telegraph Company, and the Eastern Extension Australasia and China Telegraph Company, or any of them on the other part, relating to the establishment or subsequent modifications of a joint-purse agreement for dealing with international telegrams and settlement of accounts between the parties to the joint-purse agreement; what was the actual cost at which the Indian Government transmitted telegrams over their lines from Karachi to Bushire and Fao; and what transit rate under the existing joint-purse system the Indian Government would charge over the same portion of their lines for messages to or from England handed to them by any British company not represented in the joint-purse agreement.

Lord C. Hamilton: It would be necessary to obtain the consent of several companies mentioned before the agreements referring to the joint-purse arrangements could be made public, and I am therefore at present unable to undertake to lay papers on the table. The transit rates over the Indian Government cables between Karachi and Bushire or Fao are as follows:—On messages exchanged with India—between Karachi and Bushire, 1·455f.; between Karachi and Fao, 1·905f.; on messages exchanged with countries beyond India—between Karachi and Bushire, 1.09f.; between Karachi and Fao, 1·39f. These rates are laid down in the International Telegraph Convention, and are the same for all classes of messages, whether handed over by any English company belonging to the joint-purse agreement or by any other company or foreign Government Administration. The rates can only be altered with the consent of the States interested who are parties to the International Telegraph Convention.

Sir C. Dilke asked the Chancellor of the Exchequer whether it was possible to lay before Parliament the agreements and correspondence between Her Majesty's Government on the one side, and the Eastern Extension, Australasia, and China Telegraph Company, and the Great Northern Telegraph Company on the other side, relating to the submarine telegraph cables which land at Wu-sung (for Shanghai), Hong-Kong, Labuan, Singapore, and Penang.

Mr. Chamberlain: The latest agreement—that of 1893—can be laid before Parliament if desired, but the earlier correspondence is not only in part of a confidential nature, but is also very voluminous, and extends over many years. I fear, therefore, that it could not be given.

Sir E. Sassoon asked the Under-Secretary for Foreign Affairs whether, in view of the agitation in this country for a reduction of foreign telegraph rates, Her Majesty's Government would request Her Majesty's Ambassador in Constantinople, Lord Cromer, and Her Majesty's Minister in Teheran to procure from the Turkish, Egyptian and Persian Governments respectively copies of all concessions granted to, and all agreements made with, either the Eastern Telegraph Company, the Indo-European, or the Telegraph Construction and Maintenance Company, or the agents of all or any of them, and the Indian Government.

Mr. Brodrick: In reply to the two questions of my hon. friend, I have to say that Her Majesty's Government would not feel justified in publishing or in obtaining for publication, as seems to be suggested, from one of the parties without the consent of the other copies of the arrangements referred to. The arrangements between Her Majesty's Government and Turkey and Persia have already been published.

The Rennes Telegrams.—The number of telegrams sent over the wires from Rennes on Monday night was enormous, says the *Daily Chronicle's* Paris correspondent. At the Central Post Office in the Rue de Grenelle no fewer than 200,000 words were received between 7 A.M. and 4 P.M. Five supplementary wires have been installed between Paris and Rennes, and these, in addition to the five wires in normal use, are busily employed every minute of the day.

The Telegraph Wire Export Trade.—There was rather a more active state of affairs prevailing in the export trade of this country in telegraphic wire and apparatus connected therewith during July last, the shipments during the month attaining a value of £97,635, which compares with only £27,817 in the preceding month and £45,600 in July last year. During the seven months ending with July, the value of the aggregate shipments has amounted to £599,308, an increase of £52,812 as compared with the corresponding period of last year, but a decrease of £7,965 when contrasted with the returns for the first seven months of 1897.

The Telephone Bill.—In the House of Lords on 3rd inst., the Duke of Norfolk moved the second reading of this Bill, the objects of which he explained. Lord Harris said he was a director of the National Telephone Company, but he approached the consideration of this Bill entirely from the point of view of a telephone user. He thought, says the *Times* report, that if the noble duke could appoint a committee of users of the telephone to report on the trunk service, which was under the control of the Post Office, it would report that that service was inefficient and insufficient; and as two millions of money were to be obtained under the Bill for the extension and improvement of the telephone service, he trusted it would be possible for the noble duke to utilise some portion of the money in improving and extending the trunk lines. In France, Germany and America it had been found that a monopoly could work the telephone best, just as a monopoly was found to work the telegraph best. The National Telephone Company had been held up to ridicule as supplying the worst service in the world; but curiously enough the Government in their proposals to improve that state of things had made up their minds it was wiser not to follow the example of other countries. He trusted that the policy recommended in the Bill would be successful, but he was bound to say that those who knew a great deal about the telephone system were by no means confident that the step taken by the Government in the matter was a wise one. The Bill was then read a second time.

The Telephone Service.—The Poplar District Board will not allow the National Telephone Company to lay its main lines underground until it "makes better provision for the public."

Wireless Telegraphy.—According to the daily press, experiments in telegraphy without wires are now being made by Messrs. Siemens & Halske at the entrance to Kiel Harbour. The apparatus is placed on the shore and on board the mail steamer *Prinz*

Digitized by Google

Sigismund, which plies between Kiel and Korsör. The net on the land station is 35 metres long, and is suspended from a high mast, while that on the movable station is fixed between the steamer's two masts. So far the results have proved successful and highly interesting. At a distance of 36 kilometres a telegram was successfully sent between the land and the mail steamer as she was d sappearing on the horizon.

CONTRACTS OPEN AND CLOSED.

OPEN.

Aberdeen.—August 21st. The Electric Lighting Committee wants tenders for a 12 months' supply of house service and lead covered distributing cables. See "Official notices" this week.

Barking.—August 12th. The District Council wants offers for the free wiring of premises within the area of supply. See "Official Notices" July 28th.

Battersea.—August 31st. The Vestry wants tenders for an overhead travelling crane (hand or electric), and batteries for the electricity works. See "Official Notices" July 7th.

Battersea.—August 31st. The Vestry wants tenders for steam pipes, pumps, condensers, economiser, tools, &c., also switchboard and booster. Specifications at the office of Prof. Kennedy, 17, Victoria Street, S.W.

Birkdale.—August 19th. The Urban District Council invites tenders for the transfer of its electric lighting powers.

Blackpool.—August 21st. The Corporation wants tenders for 10 double bogie tramcars. See "Official Notices" July 28th.

Carlisle.—August 17th. The Corporation wants tenders for boilers, engines, dynamos, and condensing plant. See "Official Notices" July 28th.

Darwen.—August 22nd. The Corporation wants tenders for rail bonds. See "Official Notices" August 4th.

Devonport.—August 31st. The District Tramways Company invites tenders for the following contracts: Permanent way, road bed, paving and bonding of about 4½ miles of double line, overhead construction for about 4½ miles of route. See "Official Notices" this week.

Dundee.—August 23rd. The Council wants tenders for the overhead line equipment and rail bonding of the Perth Road and Lochee tram routes. See "Official Notices" August 4th.

East Ham.—September 9th. The Urban District Council wants tenders for combined electric light and traction plant, engines, generators, overhead line equipment, cars, switchboard, arc lamps, &c., water-tube boilers, condensers, and other steam plant, electric light cable. Mr. W. C. Ullmann, The Limes, White Post Lane, East Ham, is the Council's electrical engineer. See "Official Notices" August 4th.

Germany.—Tenders are at present being invited by the Frankfort-am-Main Municipal Tramways Committee for the supply of 200 steel tyres and 40 sets of wheels and axles for electric tramcars. Tenders to be sent to the Betriebs Direction der Städtischen Strassenbahn, Frankfort-am-Main (Bockenheim), whence particulars may be obtained.

Glasgow.—August 21st. The Corporation wants tenders for the supply of switchboards, copper bus bars, and electricity meters. See "Official Notices" August 4th.

Hackney.—September 12th. The Vestry wants tenders for four sets of direct current steam dynamos (either high or low speed). See "Official Notices" this week.

Ingleton.—The Ingleton Electric Light and Power Company wants tenders for the supply of dynamos, switchboards, batteries, and wiring. See "Official Notices" August 4th.

Malmo.—September 1st. The Gas Works' directors want tenders for the erection of electricity works for the city. Particulars on application to the clerk of the Gas Works (deposit 12s).

Motherwell, N.B.—August 18th. The Commissioners invite tenders for machinery and works in connection with the proposed electric lighting of their town. See "Official Notices," July 28th.

Perth.—August 28th. The Commissioners want tenders for boilers, condensers, steam dynamos, switchboard, underground mains, and accessories. See "Official Notices" July 28th.

Portugal.—September 6th. Tenders are being invited by the municipal authorities of Cascaes, Portugal, for the concession for the electric lighting of the town.

St. Mary, Battersea.—August 31st. The Vestry wants tenders for steam pumps, pipes, condenser, economiser, &c, switchboard, and boosters. See "Official Notices" July 28th.

Southport.—The Corporation wants tenders for the supply and laying of tram rails, points, crossings, bonding, permanent way; also overhead equipment, including poles, wires, &c. See "Official Notices" this week.

Sydney (N.S.W.).—November 3rd. The Municipal Council of Sydney is inviting tenders for the construction and erection of a refuse destructor for treating 60 tons of refuse per day (24 hours).

The War Office.—The Secretary of State for War announces that tenders for various articles, including electrical instruments, will probably be invited from time to time during the next 12 months. Manufacturers who may wish to be applied to when tenders are required, should address Mr. A. Major, Director of Army Contracts, War Office, stating the particular articles they manufacture, and the names of at least two well-known firms or public bodies who have purchased from them, and are in a position to certify as to the quality of their productions.

CLOSED.

Barnsley.—The Council has accepted various tenders for brickwork, iron work, painting, &c., for electric light station buildings; also that of Messrs. Johnson & Phillips for additional plant at £2,236.

Blackpool.—The Town Council has accepted the tenders of the Langdon-Davies Motor Company for the supply of a motor-generator.

Hastings.—The Council on the 4th inst. accepted Messrs. Glover's tender for extension to mains recently advertised. The following is a list of tenders received:—

Glover & Co. (accepted)	£5,848
British Insulated Wire Company	6,424
Siemens & Co.	6,715
Borough Electrical Engineer's estimate	7,225
Callender Cable Company	7,281
The Western Electric Company	10,474

Roumania.—Messrs. R. Johnson, of Manchester, have succeeded in submitting the lowest tender for the supply of 30 tons of steel wire to the Roumanian Post and Telegraph authorities, quoting 540 francs per ton delivered.

Whitechapel.—The Electrical Committee is to have erected apparatus for purifying the feed water for the boilers at the electricity works at a cost of £1,500. The tender of Mr. John Every to supply tanks and apparatus has been accepted.

NOTES

The British Association.—In connection with the forthcoming meeting of the British Association a five days' excursion to Boulogne, Abbeville, Amiens, Arras, Brussels, Antwerp, Ghent, and Ostend, is being arranged. The excursion commences on Thursday, September 21st, and all arrangements are in the hands of Messrs. Thomas Cook and Sons. The French Association for the Advancement of Science meets at Boulogne from September 14th to 21st, and, as already intimated, the French and English Associations will exchange visits. One feature of the French gathering will be the unveiling of a statue of Duchenne, the celebrated French electro-therapeutist, and a new electro-medical section sits for the first time, which the council have formed with a desire to help forward this important branch of applied science. The president of the section is M. J. Bergonié, who has sent us the following note of papers to be contributed:—

1. Traitement par l'Electrolyse des rétrécissements en général et de ceux du canal de l'urèthre en particulier, par le Docteur H. Bordier (de Lyon).
2. Radioscopie et Radiographie Stéréoscopiques par le Professeur Marie (de Toulouse).
3. Récents progrès de la Radiographie, par le Professeur Imbert et le Docteur Bertin-Sans (de Montpellier).
4. De l'Endodiascopie, sa technique et ses résultats, par le Docteur Bouchacourt (de Paris).

The Northern Light.—The daily press says that the object of the expedition which recently left Copenhagen for Iceland under the direction of Herr Adam Paulsen, chief of the Danish Meteorological Institute, is to investigate the nature of the northern lights. In this expedition quite a number of instruments of special construction are being used in connection with photography and the measurement of electrical currents.

Digitized by Google

Obituary.—It is with very deep regret that we learn that Mr. Frank King passed away on Thurs lay last week, at the age of 45 years. For nearly 20 years he had been at work upon accumulators, and in collecting notes as to his career we find that it was in 1881 that he first directed his energies to the subject of secondary batteries generally. He then, in connection with Messrs. Beeman & Taylor, invented the "B. T. K." accumulator, which was used in Colchester in the pioneer days of town electric lighting. He joined the Electrical Power Storage Company in 1886, and his ingenuity soon displayed itself in the improvement of the "E.P.S." type of battery, notably by the design of what was known as the "1888" type. This was followed up in 1889 by the introduction of the "K" type, which was intended to meet the demands of electrical engineers of central stations for high rates of charge and discharge. Both these types of cells are being sold in very large quantities even at the present time. He was also responsible for the design and manufacture of the type of battery which worked the cars on the Barking Road Tramways for some years. In conjunction with the late M. Camille Faure he brought out the well-known form of traction battery which is designated the Faure-King, and which has been employed in working the electrical cabs in London and Paris. In 1889 Mr. King became superintending engineer of the Electric Construction Corporation, but in 1891, when the manufacture of the E.P.S. batteries was resumed by the Electrical Power Storage Company, Mr. King became manager, a position which he filled until the early part of 1898, when, owing to failing health, he was compelled to relinquish his active part in the management, but still took a part in the business as a director and consulting engineer, and, as showing the great interest which he still evinced in storage battery manufacture, even at the time of his death he was at work on an improved plate. It was not only, however, in connection with secondary batteries that Mr. King showed his skill and ingenuity. He was the pioneer of what is known as the direct current high tension transforming system, which he originally started in Colchester in the year 1882 or 1883, and on a greatly improved principle in Chelsea in 1889. In 1892 he also took up the position of managing engineer of the Chelsea Electricity Supply Company, and since that time has been responsible for all its improvements and extensions. In the year 1896 he had the misfortune to break a blood vessel in the lungs, which laid him up for some considerable time, and although he sought by change of climate to recuperate his health, he never completely recovered his strength and former vitality. In the spring of the present year he was compelled to have his arm amputated, and this shook again added considerably to his weakness. About three weeks ago he journeyed to Bexhill-on-Sea for a short spell of change of air, and the day being hot he contracted a slight sunstroke. This in his enfeebled state he was unable to shake off, and he finally passed peacefully away at his home on Thursday, August 3rd. He was buried at the Crystal Palace Cemetery on Tuesday last, in the presence of a large gathering of colleagues and friends which had assembled. Of late years on more than one occasion we have been indebted to Mr. King for valuable information and advice, and our readers will recollect that he gave evidence on behalf of the proprietors of the ELECTRICAL REVIEW in a libel action connected with a secondary battery, brought against this journal some two and a half years ago. Mr. King leaves a widow and several children, one of whom, the eldest son, is on the staff of the E.P.S. Company, and to them we offer our respectful sympathy.

It is also our sad duty to chronicle the passing away of another equally well-known secondary battery inventor, for on Friday last Mr. L. Epstein breathed his last, through sudden failure of the heart's action following some two months' illness. It must be nearly 20 years ago since we first saw Mr. Epstein experimenting with accumulators in the old electric light station of the Pilsen-Joel Company in Whetstone Park, Lincoln's Inn Fields. He went back to Germany for some considerable time and was for several years, we believe, connected with the firm of Siemens & Halske, in Berlin. He then returned to England, where he has resided for the past nine years, and during that period he perfected the well-known Epstein accumulator, first put on the market by Messrs. Woodhouse & Rawson, and later by the company bearing the inventor's name. The history of Mr. Epstein's researches during some 18 years or more may be found scattered throughout the reading columns of the ELECTRICAL REVIEW, and in that portion devoted to "Abstracts of Patents." He was an occasional contributor to our pages, and in our Jubilee issue of November, 1897, the special article on "Twenty-five Years' Progress in Secondary Batteries" was from his pen. On this branch of the electro-technical industry he was an unassuming yet great authority, a conscientious and able experimenter, he never claimed impossibilities for his cells, and his demise, at the comparatively early age of about 46 years, immediately following that of Mr. King, makes a terrible gap, which it will be difficult to fill, in the ranks of the few men who really are thoroughly conversant with their work, and to whom we look for that great desideratum of a light and durable battery of much greater capacity than we have hitherto been able to attain. In like manner to Mr. King he gave evidence for us in the same libel suit. Just previous to his illness he had been engaged in litigation with Mr. Harry Lawson over a patent for an electric motor carriage, and this, to our certain knowledge, had very gravely affected his condition. To his widow and only son we offer our heartfelt sympathy in the sudden and unexpected blow which has befallen them.

The saddest event of all in our unusually long list of obituary notices is the death of Mrs. Patchell, wife of the well-known chief engineer of the Charing Cross and Strand Electricity Supply Corporation. Mr. and Mrs. Patchell were holiday making in Cornwall, and the lady, while bathing, observed a boy struggling out of his depth. She went to the lad's assistance, and kept him afloat until a gentleman swam out to the rescue of both. The boy was safely hauled into a boat, but Mrs. Patchell when taken from the water had fainted, and death resulted from syncope. The sympathies of the whole electrical world will be with Mr. Patchell, whose grief and sorrow will, we hope, be hallowed and softened by the thought that his heroic wife came by her untimely end in the saving of another's life, the noblest and most glorious death that man or woman can desire.

Telephonists and Thunderstorms.—"The danger to telephone users in this country," says a writer in the *Outlook*, "is of the slightest. A storm-discharge usually strikes not a single wire, but a cable or whole 'line' of wires at once, thence, if moderate in amount, is promptly diffused over the whole telephonic system and rendered harmless at any individual point. It may, perhaps, have force enough to produce a dozen vibrations of the striker of the call-bell, but usually only one or two. If one wire alone should be struck or the discharge be unusually violent, the current is so much in excess of the capacity of the wire that it will either overleap the small insulators and pass down a post into the ground or overflow on to the 'ground wires,' which pass from near the cable into the ground in readiness for such an emergency. In America this incident is extremely common, and one may sit in his office and hear the lightning playing a gentle but eerie tattoo upon his telephone bell a dozen times during a thunderstorm. The shocks are occasionally severe enough to make one's head ring, and occasionally to stun for a few moments, but no serious or fatal results have, we believe, ever been recorded. And if this is the case with full-grown American or colonial thunderstorms, what is to be feared from the gentle glow-worm flickerings which are dignified by that title in this little island?" The writer is hardly correct in stating that a storm-discharge usually strikes the wires. The discharge, if it took place towards earth, would, in most cases, take the most direct route to earth, viz, the earth wires of the poles. That the lightning does strike the wires occasionally is, however, indicated by the fact that line wires are sometimes cut in two by fusion during a thunderstorm. The discharge which passes through the line wires is more often an induced effect. It is not correct to say that the discharge becomes toned down by being distributed over the whole set of wires, for it is not a fact that single-wire lines are less free from damage by lightning than those with many wires. A bucket of water thrown over a number of wires would not wet any individual wire less as a consequence of the existence of the other wires.

The Institution of Junior Engineers.—The summer meeting of this Institution is to be held from August 12th to 19th, at Portsmouth and Southampton.

Digitized by Google

The Atbara Bridge.—It appears from a Parliamentary paper issued this week that Lieut.-Colonel Gordon, who managed the purchase of the superstructure of the Atbara bridge, states that the whole question was one of quick delivery, price being practically not considered. Tenders were called for from four English and two American firms. Only one British firm made any offer, viz., the Patent Shaft and Axle Company. The Pencoyd Company, of Philadelphia, offered delivery of a suitable bridge in six weeks, and this offer was accepted, a director of the English firm acknowledging that they could not compete against such quick delivery. He also doubted whether any firm in the United Kingdom could make as good an offer as they had made, their company being, he believed, the only firm in the United Kingdom that rolled their own material. Colonel Gordon further states that the whole of the material for the bridge was inspected by a representative sent from England, from whose report, adds the colonel, "it will be seen how thoroughly the work has been carried out."

Electric Traction for the Metropolitan Underground—The *Standard* ends an editorial regarding the Metropolitan District Railway meeting with the following:—

> Electric traction, which experts believe will, before very long, be made available for the line, would add greatly to the comfort of the passengers, and might completely alter the conditions of the rivalry with omnibuses, which at present are all in favour of the traffic above ground.

Mr. Forbes's statements on Wednesday regarding the use of electric traction on the Inner Circle naturally agreed with Mr. Bell's remarks to the Metropolitan Company a few days previously. Respecting the electrical experiments, he said:—

> These experiments were being steadily continued, but this was a matter which was not so easy as some persons thought. The problem to be dealt with was not that of constructing a railway under the ground which was best adapted to electrical traction, but of converting a railway already constructed and which had other uses. It would be madness to rush into a blind expenditure without some reasonable prevision and experiment. He had, however, been told by these gentlemen that as far as they had gone, their experience induced them to believe that they would be able shortly to establish beyond question the possibility of dealing with the company's enormous traffic by electrical traction, in a manner consistent with the use of other means of traction as far as might be necessary.

Smoke!—It is astonishing what an amount of rubbish the sensational journalist can bring forth in regard to the smoke nuisance question. A reasonable movement to avoid excessive smoke nuisance we have a certain amount of sympathy with, but when a halfpenny morning paper says that the smoke fiend is eating away London, the Houses of Parliament are crumbling away, Cleopatra's Needle is losing its point, or, as it is put, "decaying," we tremble at the thought of what may come to pass. We are told that no stringent measures have yet been taken to abolish the nuisance. If the prosecutions and heavy fines imposed upon certain electricity works do not represent stringent measures, then we do not know what does. "We have grown wiser since then," says the writer, referring to events which happened 600 years ago. We thought there must be age behind such utterances. "Smoke is as unnecessary as influenza," and the writer might have added, almost as unavoidable.

Personal.—Our correspondent at Wolverhampton says that Mr. T. Parker has relinquished the position of managing director of T. Parker, Limited, but he retains a seat on the board of directors. In addition, the company have appointed him consulting electrical engineer.

We read that Mr. Robert A. Hadfield, chairman and managing director of Hadfield's Steel Foundry Company, Sheffield, is the Master Cutler elect. He is a gentleman with a high reputation for his researches and discoveries in the properties of iron and steel, and his contributions to the Royal Society are familiar to our readers.

Marriage.—Mr. Howard Marryat (of Marryat & Place) was married at Richmond, on Saturday last, to Miss Maude Mortham.

Serious Shock Fatalities at Omaha.—We take the following from yesterday's *Westminster Gazette*:—"A Central News telegram from New York this morning states that a great fire broke out in Omaha last night, and that four firemen coming in contact with a live electric wire were instantly killed, while two others were fatally injured."

Appointment.—Mr. P. T. Macnamara has been appointed Assistant Superintendent of Telegraphs in Ceylon.

NEW COMPANIES REGISTERED.

Queen's Dock Electric Works, Limited (63,113).—This company was registered on July 27th, with a capital of £5,000 in £1 shares (2,000 preference), to acquire, take over as a going concern and carry on the business of electricians, electrical engineers and suppliers of electricity carried on by the Globe Electrical Company at Liverpool and Belfast. The first subscribers (each with one share) are:—P. J. Pakeman, 28, Queen's Avenue, Muswell Hill, N., clerk; H. M. Cordrey, 40, Harders Road, Peckham, S.E., solicitor's clerk; A. W. Read, 11, Ironmonger Lane, E.C., solicitor; J. R. Pakeman, 11, Ironmonger Lane, E.C., solicitor; J. E Simister, 47, New City Road, Plaistow, clerk; R. B. Cannings, 81, Camilla Road, South Bermondsey, clerk; and E Smith, 10, Ironmonger Lane, E.C., secretary. Registered without articles of association. Registered office, 75, Kitchen Street, Queen's Dock, Liverpool.

Southern Electrical Installation and Wiring Company, Limited (63,116).—This company was registered on July 27th, with a capital of £10,000 in £1 shares (2,500 preference), to acquire two businesses carried on at Hastings as "Bruce & Co." and "F. Wordley" respectively, to adopt agreements (1) with F. Bruce, (2) with F. Wordley, and (3) with the mayor, aldermen and burgesses of the borough of Hastings, and to carry on the business of electrical apparatus manufacturers, suppliers of electricity for light, heat, and motive power, telephone and telegraph constructors, &c. The first subscribers (each with one share) are:—W. J. Laite, Pelham Hall, Hastings, journalist; A. L Sayer, Westfield, Sussex, solicitor; H. S. Colt, 33, Havelock Road, Hastings, solicitor; A F. Wood, Gatefield, West Hill, Hastings, clerk; L. F. St. John, 26, Havelock Road, Hastings, auctioneer; H. Kent, 68A, All Saints Street, Hastings, clerk; and Captain A. H. A. Cohill, 16, Pevensey Road, St. Leonards. The number of directors is not to be less than three nor more than five; the subscribers are to appoint the first; qualification, £100; remuneration, £75 per annum, dividible. Registered office, 33, Havelock Road, Hastings.

Browett, Lindley & Co., Limited (63,128).—This company was registered on July 28th, with a capital of £120,000 in £1 shares, to acquire the business carried on by Browett, Lindley & Co. (incorporated in 1890), at the Sandon Engine Works, Patricroft, near Manchester, and to carry on the business of mechanical, electrical and hydraulic engineers, ironfounders, machinists, tool makers, millwrights, fitters, founders, smiths, builders, hardwaremen, &c. The first subscribers (each with one share) are:—T. Browett, Sandon Works, Patricroft, engineer; H Lindley, Sandon Works, Patricroft, engineer; F. C. Gibbons, Sandon Works, Patricroft, engineer; W. Stead, Sandon Works, Patricroft, engineer; W. R Goulty, Kurnman, Altrincham, engineer; A. Shuttleworth, Ducby Chambers, Clarence Street, Manchester, chartered accountant; and S. B. Beardley, Sandon Works, Patricroft, near Manchester, secretary. The number of directors is not to be less than three nor more than seven; the first are William R. Goulty, Thomas Browett, Herbert Lindley, Frederick C. Gibbons, and William Stead; qualification, £500; remuneration as fixed by the company. Registered office, Sandon Works, Patricroft, near Manchester.

Renewable Electric Lamp Company, Limited (63,144).—This company was registered on July 29th, with a capital of £150,000 in £1 shares (50,000 6 per cent. cumulative preference), to carry on the business of manufacturers, renewers, and repairers of and dealers in lamps, wires, and lines of all kinds; electricians, mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power and otherwise, manufacturers of electrical apparatus and fittings, &c. The first subscribers (each with one ordinary share) are:—H. E. Kershaw, 8, Onslow Gardens, Highgate, N., manufacturer; J. Atherton, Singleton, Huyton, Lancashire, manufacturer; C. Howard, 4, Park Lane, St. James's, S.W., electrical engineer; F. G. W. Leslie, 15, Union Court, Castle Street, Liverpool, solicitor; A. W. W. Miller, Savoy Hotel, Strand, gentleman; M. F. Armstrong, 6, Walbrook, E.C., gentleman; J. Spencer, 3, Firsby Road, Stamford Hill, N., gentleman. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification, £250; remuneration, £150 each per annum (an extra £50 for the chairman), and a share in the profits.

Electric Light Railways Limited (63,060).—This company was registered on July 24th, with 20 members (the subscribers to the memorandum of association being liable for £5 each and other members for £50 each in the event of winding up), to promote, construct, work and maintain railways, light railways, tramways and auxiliary railways, and to carry on the business of

Digitized by Google

electrical and general engineers, telegraph and telephone constructors, &c. The first subscribers are:—W. I. T. Goatley, 93, Chancery Lane, W.C., accountant; J. Battam, 23, Rood Lane, E.C., solicitor; W. A. Davies, Broadway, Ealing, W., solicitor; W. S. Sargeant, Strand-on-the-Green, Chiswick, W., engineer; T. Hutchinson, Ealing, solicitor; A. F. May, 341, Strand, W.C., advertisement agent; A. Blyth, Lancaster Place, Hampstead, engineer; S. H. Doubleday, 27, Burlington Gardens, Chiswick, chartered accountant; N. Caunter, 12, Heathcote Street, Mecklenburgh Square, W.C., accountant; and G. Cuddon, 140, Camden Road, N.W., gentleman. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first; qualification, membership (guaranteering £50); remuneration, £1,000 per annum, divisible.

Sturtevant Engineering Company, Limited (63,065).—This company was registered on July 24th, with a capital of £60,000 in £1 shares, to acquire and take over as a going concern the business of engineers, merchants and manufacturers, now carried on at 75, Queen Victoria Street, E.C., by George A. Mower, under the style or firm of the "Sturtevant Engineering Company," to adopt an agreement with the said vendor and to carry on the business of mechanical and electrical engineers, merchants and manufacturers of machinery, tool makers, metal workers, brass founders, boiler makers, smiths, &c. The first subscribers (each with one share) are:—W. J. P. Moore, 153, Queen Victoria Street, E.C., engineer; C. A. Knight, 6, Upper Avenue Road, N.W., engineer; G. A. Mower, 75, Queen Victoria Street, E.C., engineer; P. N. Perrin, 75, Queen Victoria Street, E.C., clerk; C. E. Fox, Christ Church Schoolhouse, Camill Road, Brixton, S.W., clerk; W. J. Bassett, Craigleith, King Charles Road, Surbiton, engineer; and W. C. Burrows, 19, Vassall Road, S.W., engineer. The number of directors is not to be less than three nor more than five; the first are George A. Mower, Charles A. Knight, and William J. P. Moore; qualification, £1,000; remuneration, 5 per cent. of the net profits divided amongst them.

South Staffordshire Tramways (Lessee) Company, Limited (63,160).—This company was registered on July 31st, with a capital of £150,000 in £5 shares, to acquire a lease of certain tramways now belonging to the South Staffordshire Tramways Company, and to carry on the business of tramway and light railway proprietors, mechanical and chemical engineers, electricians, suppliers of electricity, manufacturers of electrical apparatus and fittings, carriers of passengers and goods, &c. The first subscribers (each with one share) are:—E. Garcke, Donington House, Norfolk Street, W.C., managing director; J. Raworth, 2, Queen Anne's Gate, S.W., civil engineer; G. Stevens, Donington House, Norfolk Street, W.C., secretary; C. H. Dade, Donington House, Norfolk Street, W.C., assistant secretary; S. Sisson, Donington House, Norfolk Street, W.C., civil engineer; H. M. Sayers, Donington House, Norfolk Street, W.C., electrical engineer; and H. S. Hodgson, Donington House, Norfolk Street, W.C., secretary. The number of directors is to be five, three of whom are to be nominated by the British Electric Traction Company, Limited, and two by the South Staffordshire Tramways Company: no qualification for the first directors; qualification of subsequent directors, £100; remuneration, £500 per annum, divisible. Registered office, Donington House, Norfolk Street, Strand, W.C.

Electrical Transmission Company, Limited (63,173).—This company was registered on August 1st, with a capital of £30,000 in £5 shares, to acquire and take over as a going concern the business carried on at Hammersmith as "The Electrical Power Transmission Company," to adopt an agreement with Powell, Jones & Co., and to carry on the business of electricians, mechanical engineers, suppliers of electricity for the purposes of light, heat and motive power, &c. The first subscribers (each with one share) are:—E. Wahab, Golrings, Loughton, Essex, East India merchant; C. Powell-Jones, 7, East India Avenue, E.C., East India merchant; W. E. D. Simpson, 50, Cannon Street, E.C., paper maker; A. R. Clarke, 8, Southwood Avenue, Highgate, assistant; W. E. Starling, 47, Stapleton Hall Road, Stroud Green, N., accountant; T. J. Young, 83, Kent House Road, Beckenham, wharf manager; and D. C. Lee, 46, Queen Victoria Street, E.C., solicitor. Powell, Jones & Co. are to be the first managing agents. Remuneration as fixed by the company.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

F. H. Royce & Co., Limited (41,362).—This company's annual return was filed on July 10th, when 6,000 preference, 21,480 ordinary, and 500 deferred shares were taken up out of a nominal capital of £60,500 in 6,000 £5 preference shares, 30,000 £1 ordinary shares, and 500 £1 deferred shares. £1 5s. has been called up on 6,000, and £1 on 9,466, the remaining 12,514 £1 shares being considered as fully paid. £16,966 has been received.

Electric and General Investment Company, Limited (31,506).—This company's annual return was filed on July 12th, when 20,000 ordinary and 100 founders' shares were taken up out of a capital of £200,000 in 39,900 ordinary and 100 founders' shares, all of £5 each. £1 had been called up on the ordinary, and £5 on the founders' shares, resulting in the receipt of £20,500.

CITY NOTES.

The British Westinghouse Electric and Manufacturing Company, Limited.

An extraordinary general meeting of this company was held at the Cannon Street Hotel on Wednesday, 9th inst., for the purpose of complying with the requirement that a general meeting shall be held within four months of the incorporation of the company, and for the purpose of considering and passing resolutions as follows:—

1. Authorising the directors to carry into effect, with or without modification, an agreement dated August 1st, 1899, and made between the Westinghouse Machine Company of the one part and the company of the other part;
2. Increasing the capital of the company to £1,750,000 by the creation of 25,000 ordinary shares of £10 each, such shares to rank in all respects *pari passu* with the existing ordinary shares in the company.
3. Increasing the maximum number of directors from nine to 11, and appointing three additional directors;

And also the following resolution, which, if passed by the required majority, will be submitted hereafter for confirmation as a special resolution:—

4. "That Article 83 of the company's articles of association be altered by the addition thereto at the end of the words 'The directors may also from time to time appoint any qualified person an additional director provided the prescribed maximum number of the board for the time being be not thereby exceeded.'"

The agreement which has been entered into, subject to the approval of the company in general meeting, provides for the acquisition by the company of certain rights, patents, and assistance from the Westinghouse Machine Company of Pittsburg, Pennsylvania, in consideration of the issue to that company or its nominees credited as fully paid up of the 25,000 ordinary shares proposed to be created, the Westinghouse Machine Company covenanting to subscribe or procure subscriptions within a certain period for £250,000 nominal value in preference shares of this company for its general purposes. The company proposes after the expiration of 12 months from the special settlement on the Stock Exchange of the existing preference shares to submit resolutions for the increase of its preference shares by £500,000 nominal value for general purposes in view of the enlargement of the company's sphere of operation. At the conclusion of the general meeting, a meeting of the holders of the existing ordinary shares of the company was to be held for the purpose of giving their separate consent to the resolutions.

Mr. C. W. Benson, who presided, said that so far as the statutory meeting was concerned, there was no particular business to bring before them, as the company's operations had not yet reached that stage when a report could be laid before them. The more important part of the business for consideration was the series of resolutions. Shareholders were perhaps surprised that when the prospectus was issued so recently as July 10th no mention was made of any arrangement with the Westinghouse Machine Company. That was an entirely different company from the Westinghouse Electric and Manufacturing Company, with whom they made their original contract. The business before them was not mentioned in the prospectus, because it was not then in contemplation by the directors; but after the formation of the company third parties made an offer to Mr. Westinghouse to take over the Westinghouse Machine Company's business, in order to manufacture gas engines for Great Britain and its dependencies, and it was then that Mr. Westinghouse gave this company the first offer. The company was formed for making electrical appliances of various descriptions, but electrical appliances all needed some motive power to drive them. It was obvious that it would be convenient to make suitable machines for electric driving from the same works, and that the two classes of machinery could be produced with economy at the same works. Experiments had been in progress for 10 years under Mr. Westinghouse, with the object of producing a really excellent motive power, and the Westinghouse Company was formed to manufacture gas engines. When the formation of the company was determined on, and the details arranged, several months ago, small gas engines up to 250 B.H.P. had been proved to be a success, but the larger sizes, which presented the most profitable commercial field, were still in the experimental stage. In October, 1898, a 650-B.H.P. engine was erected at Pittsburg, and the performance thereof in actual progress had been carefully watched. The engines installed at Chelsea had been examined by some of the highest authorities in this country, and had received very great praise. A 1,500 B.H.P. is now coming through the shops at Pittsburg, and the engineers were confident of its success. Their type of gas engine thus lent itself to sizes much larger than any before possible, and the steadiness of running enabled it to be used for electric lighting, for which purpose gas engines of any considerable sizes had not yet been applied very satisfactorily. Responsible third parties watching the developments of the gas engine, made an offer to Mr. Westinghouse to take over the business. He thought it his duty to come to the board of this company and give them an opportunity of taking over at the same rates. The board consulted Lord Kelvin, and came to the conclusion to acquire the business, patent rights, and assistance of the Westinghouse Machine Company. Lord Kelvin inspected the engines and considered them no longer an experiment but a success, and he referred to the advantages of combining the manufacture of the gas engines in the same works as the electrical apparatus. The board found the area of land they proposed to acquire was sufficiently large to erect a factory to deal with both manufactures. The Westinghouse Machine Company was willing to take the consideration in ordinary shares, which would rank behind the preference shares, but as it was believed that the two manufactures combined would require increased working capital to deal with them effectually, it was believed that after 12 months a

Digitized by Google

further issue of preference capital could be made. This should not be an occasion for anxiety to the shareholders, because certain responsible persons engaged in the concern had already decided to find £250,000 additional preference capital when required. They would have found it immediately, but as the Stock Exchange rules did not allow of an issue being made within 12 months of the issue of the prospectus, and, furthermore, as the money would not be required for 12 months, the arrangement had been made to put that subscription off for that period. The money was sure, and it could not be other than an advantage to the company to have the additional £250,000 working capital added to its resources. Mr. Westinghouse was on his way to America, but he had written to say that an inspection of the two separate works at Pittsburg showed that there could be carried on within either of the two works the manufacture of both classes of apparatus, and that in general the same class of large and small tools were employed in both kinds of manufacture. He also emphasised the other economies and conveniences that would result from having one works. There would, of course, have to be two classes of engineers—those familiar with electrical construction and those with engineering and general gas and steam engineering. Such engineers working under a single management would become familiar with both classes of construction. The chairman said that as to Article 83, negotiations were on foot between the board and the persons proposing to find the additional money, for the appointment of additional directors, but the time had not yet arrived for their appointment, nor were all the names definitely settled, but they would be all gentlemen whose services would be of great value to the company. He then formally moved the adoption of the resolutions given above.

Mr. Joseph Lawrence, in seconding the resolution, told what had happened to the English company. The company was constituted with a million and a half nominal capital. Half a million in ordinary shares was allotted to the Westinghouse Company at Pittsburg for patents, assistance, plans, &c.; half a million of the preference capital was allotted to the public, and applications came in for £632,280, the list of subscriptions to that amount embracing some of the most prominent names in the world of finance and banking in London and England. The board were arranging for the purchase of land for building the works at Manchester. They chose a site at Manchester instead of London, &c., because it afforded facilities for obtaining cheaper land, a large and abundant supply of the best skilled labour, and the situation was in the centre of the manufacturing industries. An architect had been engaged, and Mr. Westinghouse had gone to America with him to confer with him at his own works in Pittsburg, with a view to getting the best points from those works. Mr. Westinghouse was of opinion that the building of the works would proceed in a manner unprecedented in England, and put up in a record time. It was possible that the Carnegie Company, of Pittsburg, might supply the ironwork for the works within four months. If they let out contracts in England just now for such works the makers could not deliver within two or three years. That made it possible to proceed with double-quick time. This was not a company on paper, it was a living company buying a living business, increasing by leaps and bounds. The French company formed by Mr. Westinghouse had only been in existence a short time, but had obtained contracts amounting to several millions of francs in connection with the Paris Exhibition and other great works. One day's work recently amounted to 3½ millions of francs. Business promised to be equally prosperous in this country. Regarding the amalgamation question, the chairman said that the proposed amalgamation with the engine company was not contemplated at the time the prospectus was issued. That was strictly true in terms, but the subject was not absent from the minds of Lord Kelvin and Mr. Parsons, their colleague, nor was it absent from his own mind. Whilst the negotiations were in progress it was decided that it was better to carry out the arrangements for the electrical business first and discuss amalgamation with the other afterwards. The advantage of the amalgamation was so apparent as not to need his advocacy. The only question was deciding what was the phychological moment. If they had not settled when they did they might have had to pay higher terms for effecting the amalgamation. Mr. Westinghouse had practically produced an engine of all grades up to 1,500 H.P. In this country, up to quite recently, they thought it a splendid thing if they could do 200 H.P. His engines had been the subject of years of experiment. Not only was his system likely to supplant the present type of gas engine in use in this country, but it would make a trade for itself. It did away with the pulley band, because the shaft was directly connected with the engine. That was one of many valuable features in the Westinghouse engine. They were convinced that there was a field for gas engines over and above the electrical business. This was not the first time Mr. Westinghouse had made his bow to the British public. They all knew of the gigantic success of the Westinghouse brake. His electrical business had begun in a small way, and had developed to such an extent, that it was now represented by a live capital of $13,500,000. Orders were flowing in upon him, so that it became well nigh impossible for him to conduct his European business, and it became necessary that he should seek the assistance of European capitalists in forming a branch of his business here. England was in a deplorably backward state as regards electrical development. It was perfectly painful for anybody who had watched the progress in Germany and America, to see the backward position we are in in England. It was a solid fact, and might be news to some of them that an important railway contract that was let in the first instance to an English firm, could not be carried out by that firm because of the largeness of the contract and the time involved. It was taken up by a German firm, and the length of road was to be constructed in London by German capital and German labour. That was a reproach to British enterprise. This company could congratulate itself upon a happy combination of English and American capital. The list of shareholders included the leading capitalists, from Lord Rothschild downwards. They had a solid business and solid backers. He was going to Pittsburg himself in a fortnight, and the insight and experience he would get at the works would be at the company's service. He was perfectly convinced that this was a sound business, which would be highly remunerative if carefully managed. He seconded the resolutions.

Mr. Ormrod (a shareholder) expressed very strong feeling of dissent at the proposals contained in the circular. His firm acted as the Manchester brokers of the company, and they and a considerable number of friends were shareholders. The prospectus was dated July 10th, and the agreement the board had made with the Westinghouse Machine Company was dated August 1st. It seemed to him a very peculiar thing, in fact a most startling and unique thing, that a circular of that kind should be sent out within so short a period of the issue of the prospectus. There was not a word mentioned in the prospectus as to the existence of a Westinghouse Machine Company, and either the amalgamation should have been known about at that time or it must have been very hastily considered since. He and his friends did not know of the existence of such a company. They had received no information at all as to its profit-making capabilities. The Westinghouse Electric Company—the British Company—they understood to be doing a live business. There were actual results to show, but the Machine Company, so far as they knew, might never have passed the experimental stage. He had had letters from many shareholders in the Manchester district, and they were unanimous in expressing a very strong feeling of dissent at the proposals. No doubt the board were well able to carry their proposals, and he had not come with proxies or anything of that kind. The chairman had made possibly a more or less satisfactory explanation of the circumstances, but to justify such a course as was proposed needed a very satisfactory explanation indeed. He would suggest that a very full and explicit explanation be sent to the shareholders, many of whom were unable to be at the meeting, before formally passing the resolutions. He and his friends applied for shares because it was an electric company. They knew nothing whatever about the machine company. They believed in the possibilities of an electrical company. There might be equally good, if not greater, possibilities in front of the machine company, but they knew nothing about that. He had heard big names mentioned as the parties who were prepared to find that additional £250,000, and he was very much surprised at their countenancing such a proceeding.

The Chairman, in reply, said that what Mr. Ormrod had said was exactly his own feeling, and if he had not felt it his duty absolutely in the interests of the shareholders from the evidence that the directors had, which must be submitted in this way, owing to the circumstances of the case, he would never have voted for it.

Mr. Lawrence said that, having an eye to the value of the preference shares, this was a good bargain, attested by the fact that there was an organisation ready to take the business. He took it that Mr. Ormrod looked at the matter from the position of an ordinary shareholder and underwriter. The preference shares would absolutely benefit by the proposed amalgamation. If Mr. Westinghouse and others chose to give them something of a valuable nature, patents, plans, &c., in return for ordinary shares which had to wait for one, two or three years for a return, that was no concern of his. He was looking only at the preference shareholders who subscribed the cash capital. Several of the leading shareholders were informally consulted, and approved of the scheme. There was absolutely no dissent on the board as to the wisdom of the policy. If it was postponed for 12 months the gentlemen who were finding the additional capital would not hand it over for the same amount of money as to-day. It was absolutely essential to the business that the amalgamation should take place. It would be a retrograde step to postpone the adoption of the resolution.

After a few further remarks had passed between Mr. Ormrod and Mr. Lawrence, the resolutions were carried unanimously, and the usual vote of thanks closed the meeting.

Anglo-American Telegraph Company, Limited.

Mr. F. A. Bevan presided at the half-yearly meeting of this company at Winchester House last Friday. He said the directors were pleased to give such a very satisfactory statement with regard to the receipts for the half-year. Compared with the corresponding half-year of 1898 a falling off might naturally have been expected, as at that time the Spanish-American war was raging, and an immense amount of traffic was sent over their lines, but it was a matter for congratulation that not only had the receipts equalled in amount those of the first half of 1898, but had actually exceeded it by £256. Looking back and taking the figures for the corresponding half-years from 1894 they found that the increase had been gradual and steady from £134,000 to £202,000 in five years. The expenses this year are only larger over those of 1894 by £5,300. The proportion of expenses in 1894 was 41·41, and in 1899 30·19. In addition to ordinary revenue the *Minia* had earned £5,987 more. Since the last meeting they had lost the captain of the *Minia*. To Captain Trott they were greatly indebted for the vast amount of good work that he did, and they hoped that his successor would equal him in his skill. That source of revenue might fairly be called accidental in more senses than one, and therefore could not possibly be relied upon. The accounts are now presented in such a form, that shareholders could at once compare the figures of one half-year with the other. To refer to these briefly, taking into account on one side the increase of the *Minia's* expenses, owing to the amount of employment she had had, and on the other the reduced expenditure on cable, arising from the fact

Digitized by Google

that they had had to spend less upon their repairs in the shape of cable, they found that the total increase of receipts had been £6,154. There was a net reduction of expenses of £590, and an increased balance brought forward of £377, so that the total increase of revenue earned and carried forward was £7,121, being £24,701 as against £17,580. That was a most satisfactory statement. During the past year the increase in the renewal fund had been £53,129, so that not only had they had a very satisfactory half-year so far as working was concerned, but they had added to the strength of the company. In the balance-sheet sundry debtors, including the traffic balances, stood at £120,000—£60,000 more than last year. Their debtors were solvent people. They were Governments, and the companies who were in alliance with them. Some of that money had been already paid, and the rest was sure to come. The money owing being so large, the cash in hand was correspondingly small, but that was to some extent righting itself, and shortly would have done so completely. They had begun the new half-year very well, the increase in the gross receipts for the month of July being £2,700, and the *Minia* had already earned during July as much as she did during the whole of the six months in 1898, and there was no doubt that she would earn more. Therefore, barring some extraordinary accident, they would have a very good half-year. As regards the German Cable Company, they had no doubt seen paragraphs in the papers as to what the German Government, or new German Cable Company was going to do, but he could give them no definite information upon the point. The subject had occupied the attention of the directors during the past few months, and it would not be owing to any want of zeal or energy on their part that things turned out not exactly as they hoped and wished. As to what had been called the interminable French law suit, he was glad to tell them it was not altogether interminable. He could say something definite about it, though they had not yet got any cash. In May last, the Court of Appeal, of Rouen, gave judgment in favour of this company for £258,000, less such amount as a committee of experts might determine to repay the value of the assistance rendered by the French Company to the Anglo-American Company by having placed its new cable at the service of the Anglo-Company during the period of performance of the joint-purse agreement, so far as such assistance might not have already been paid for. So far as the board knew, all such assistance *had* been already paid for—every message was paid for as it was sent. Therefore apparently they might look forward to a very nice little addition to their renewal fund, but getting the money was different from a judgment in your favour. As to when they would get the money, or how much they would get, the shareholders knew as much as he did. He thought the decision would justify the directors in the shareholders' eyes in not having dropped the matter, although it might have appeared that they were fighting for a shadow. He would be very pleased when he could announce that they had got the money. He moved the adoption of the report, which appeared in our last issue.

Mr. C. Burt seconded the motion, which was carried unanimously, and the usual vote of thanks closed the meeting.

The City of London Electric Lighting Company, Limited.—Warrants have been posted for the payment of an interim dividend for the half-year ended June 30th, 1899, at the rate of 6 per cent. per annum on this company's 6 per cent. cumulative preference shares (£400,000 in 40,000 shares of £10) Nos. 1 to 40,000.

Yesterday's City Meetings.—On Thursday a meeting of the National Telephone Company was held at Cannon Street Hotel, and of the Waterloo and City Railway at Waterloo. Reports of the proceedings will appear in our next issue.

TRAFFIC RECEIPTS.

The Blackpool and Fleetwood Tramroad Company.—The receipts for the week ending August 5th, 1899, were £1,359 13s. 8d.; receipts for week ending August 5th, 1898, £1,125 18s. 4d.; aggregate, July, 1899, to date, £5,818 5s. 7d.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending August 4th, 1899, were £8,660 5s. 2d.; corresponding period 1898, £8,981 18s. 5d.; decrease, £321 13s. 3d. (Bank Holiday week).

The City and South London Railway Company.—The receipts for the week ending August 6th, 1899, were £933; week ending August 7th, 1898, £1,105; decrease, £172. Total receipts for half-year, 1899, £5,632; total receipts corresponding period, 1898, £5,861; decrease, £229. Miles open, 8½.

The Dover Corporation Electric Tramways.—The receipts for the week ending August 5th, 1899, were £272 9s. 11d.; week ending August 6th, 1898, £272 12s. 7d.; decrease, 2s. 8d. Total receipts to date, 1899, £5,485 5s. 7d.; corresponding period, 1898, £4,446 18s. 9d.; increase, £1,038 6s. 10d. Miles of track open, 1899, 8; 1898, 8. Car miles run, 1899, 4,553; 1898, 3,906. Number of cars, 1899, 11; 1898, 10.

The Dublin United Tramways Company.—The receipts for the week ending Friday, August 4th, 1899, were as follows:—D. U. T. Co., horse cars, £2,246 18s. 11d.; ditto, electric cars, £1,265 18s. 4d.; D. S. D. Co., electric cars, £1,155 8s. 8d.; total, £4,668 5s. 11d.; corresponding week last year—D. U. T. Co., horse cars, £2 800 8s. 7d.; ditto, electric cars, £787 12s. 6d.; D. S. D. Co., electric cars, £1,312 6s. 0d.; total, £4,880 7s 1d.; decrease, £212 1s. 2d. Aggregate to date, £22,758 19s. 2d.; aggregate to date last year, £22,745 17s.; increase to date, £13 2s. 2d. Worked:—The mileage open is 18 miles electrically, 26 miles by horses, as against 12 miles electrically, and 30 miles by horses, for the corresponding period last year.

The Liverpool Overhead Railway Company.—The receipts for the week ending August 7th, 1899, amounted to £1,654; corresponding week last year £2,007; decrease, £353. 1898 includes Bank Holiday.

The South Staffordshire Tramways Company.—The receipts for week ending August 4th, 1899, were £746 13s. 2d.; aggregate receipts for 31 weeks, £19,967 8s. 5d.; week ending August 5th, 1898, £881 13s. 11d.; aggregate receipts for 31 weeks, £19,272 6s. 11d.

STOCKS AND SHARES.

Wednesday Evening.

The hot weather and the holidays have combined to restrict business in electrical undertakings to the smallest compass, but as the rest of the Stock Exchange is suffering from precisely the same complaint, those who are interested in electrics have no more reason for grumbling than the rest of the house. Indeed, there is a cause of thankfulness to notice how steadily quotations are maintained, because a stagnant market is usually inclined to the down grade. There is hardly a bargain doing in electrical railway descriptions, but the best of prices exhibits no alteration. By the way, the Stock Exchange official list quotes City and South London new Ordinary, with £3 10s. per share paid up, at 2½—3½, while the £10 fully-paid ordinary are only 6¼—6¾. The former is, of course, a mistake. Bordeaux tramway shareholders, who have not yet done so, should immediately avail themselves of their option to purchare shares in the Compagnie Francaise des Tramways Electriques et Omnibus, as there is a premium of £2 per share on them.

Concerning the other varieties of traction shares there is not very much to say. The quiet reading of Light Railway Bills in Parliament goes on month by month, and its fruit will probably be ripening soon, if what we hear about sundry new issues to be made shortly is correct. Anglo-Argentine Trams are hard at 4¼, and Buenos Ayres and Belgrano "A" Preference are well maintained at 4½, the pending call upon the latter having had no effect upon the price. The 4½ per cent. Debentures of the Tramways Union are nominally 101 to 105, but holders are naturally keeping the market very short of stock, as there seems no doubt but that the debentures will be paid off at 110 at once, instead of at par in 1918.

Among the electricity supply companies the noticeable feature of the week has been the fluctuations in City of Londons. After the hurried scamper to get out on the part of those who were so disappointed at the passing of the dividend, it was only to be expected that a reaction would occur. Besides, as we urged when writing last, the company's directors adopted the only safe course, and it was the calm consideration of this view that materially assisted in putting up the price of Citys to the extent of a point, only, however, to relapse again as more sellers came in on the rise. Charing Cross fail to recover the ground they lost last week, and the market is very curious to know how the money will be raised for bringing the company into the City. The share capital of the Charing Cross, *i.e.*, a quarter of a million sterling, is all issued, and its £70,000 worth of 5 per cent. debentures are redeemable at par next year. The company, however, possesses borrowing powers to the tune of £150,000.

Glancing over the remainder of the list, it is observable that prices manage to retain their quotations of last Wednesday, but are unable to make up for the fall which lowered the market all round 10 days back. This is due partly to the fact that some fears are entertained for the companies' prosperity if copper keeps at its present price. It has gone up so rapidly within the last six months, and shows such apparent strength, that it was argued electric supply companies would feel the difference keenly when they came to extend their cables, as they constantly have to do. The same line of reasoning applies, of course, in a much more limited way, to telegraph and telephone companies, but so far this factor has not seriously entered into Stock Exchange consideration. Metropolitan Electric, both old and new, have added to their quotations during the week.

Eastern Telegraph Ordinary stock has been more cheerful, principally because nothing has lately appeared in the papers about the new Pacific cable. The 5 per cent. Debentures rose a point upon their approaching redemption this month. These bonds were issued 20 years ago, in order to acquire £200,000 worth of shares in the Eastern and South African Company, Limited. A large part of the issue has already been converted into the 4 per cent. Debenture stock of the Eastern Company. Of the American companies, the Anglo-American is still the market favourite; but Directs also rose a fraction.

Manufacturing shares are steady. Wireless Telegraph have moved up 10s., but no recordable change is shown by the Telegraph Manufacturing issues. Henley's 7 per cent. Preference have been inquired for, and reflect the demand in their price. Callender's Cable Ordinary are unchanged; the Preference are quoted 5½—6. Telegraph Construction have regained part of the dividend, and this department seems to be worth the investor's attention. National Telephones are being bought, and the anticipated trouble in Glasgow has quite blown over.

THE MUNICIPAL ELECTRICAL ASSOCIATION.

THE ARRANGEMENT OF STEAM AND OTHER PIPES, AND THEIR FITTINGS.

By J. E. Edgcome, M.I.M.E., M.I.E.E.

Borough Electrical Engineer, Kingston-upon-Thames.

The subject of steam and other piping is one of the greatest importance to engineers of central stations, and, indeed, to all who have to deal with steam plant. It is a subject upon which volumes might be written and still leave much unsaid.

The author does not pretend to advance any especially new or original information, but rather a series of notes based on some little experience, in the hope of eliciting what should prove to be a most interesting discussion, and a discussion from which every member may be able to carry away some useful suggestion, to be put into practice when laying down a new generating station, or when carrying out the inevitable extension of his present works.

The arrangement of piping referred to in this paper is proposed for small or for moderate sized stations, which form the majority, rather than for those very large stations to be found in a few of the big cities, and where, possibly, special arrangements are necessary.

Steam Pipes.

The author is of opinion that in the majority of cases, the best and most favourable arrangement of steam piping is in the form of a steam ring, running from the boiler house through the engine house and returning to the boiler house, as shown in fig. 1.

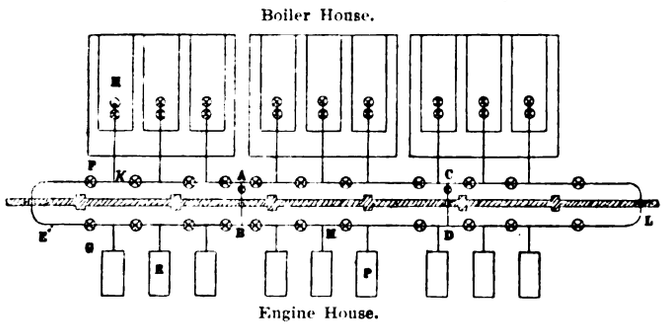

Fig. 1.

It is advisable that the ring should be cross connected at two or more places, as shown at A B and C D, so that in the event of repairs being necessary to any pipe—say at E—the closing of the valves, F G, does not necessitate, in case boiler H is under steam, that the steam should pass to the engines—say P or R—by the long route, K A L M, but by the shorter route, K A B M.

This arrangement will also allow of considerable lengths of steam pipe being cut out when the engines and boilers upon them are not in use, and will be found to give greater flexibility to the ring system.

In most cases, particularly when the engine house and boiler house are approximately on the same level, it is usually more convenient to carry the steam piping overhead, and where a single line of boilers is installed backing towards the dividing wall, and similarly a single line of engines is laid down with the engines abutting towards the same wall, it is extremely simple to carry out the steam ring system.

Where a double row of engines is installed the system becomes a little more complicated, and it is usually advisable to form a second loop of steam piping in parallel with the main ring within the engine house, feeding the engines on either side, the engines in that case facing one another with the machines outward.

Serviceable and reliable steam pipes may be made up of lap-welded mild steel with heavy wrought-iron flanges, the flanges being screwed on hot and the ends brazed. The flanges must, of course, be faced up to enable good joints to be made.

In larger sized steam pipes it will be found that the joints can be kept tighter by having the flanges made with a slight boss, which is faced up for the joint, instead of the whole of the flange being faced up for that purpose, as shown at A in fig. 2; from $\frac{1}{16}$ inch to $\frac{1}{8}$ inch is sufficient for the thickness of the boss.

Steam pipes, where supported on brackets or columns, should be carried on rollers to allow of free contraction and expansion.

Joints.

With the higher steam pressures now in use, care and discrimination are required in making and keeping good sound joints. There are innumerable makes of jointing material on the market. Rubber prepared with plumbago makes a good sound joint, which requires taking up when steam is admitted to the pipe, as the material softens with the heat, although it sets into a hard permanent joint when tightened up.

An admirable and reliable joint is one made with corrugated brass rings, painted with thin red lead.

Drainage.

One of the most prolific causes of trouble with steam piping is that from accumulation of water, and too much care cannot be taken in thorough draining of the pipes.

For this purpose a number of separators should be fitted in the ring on the boiler side to collect the water from the steam where it leaves the boilers, and, in the author's opinion, it is certainly advisable that every engine should be fitted with its own separator, to deal with any water which may be carried over from the main steam pipe.

To deal, however, with the water which will, notwithstanding, collect in the main steam ring in the engine house, it is advisable to connect the ring in several places to steam traps, similar traps being connected to the separators of the engines.

The author has found from experience that, to permanently connect the engine separators to steam traps, deals more effectually with the water trouble than to constantly blow out the water from the

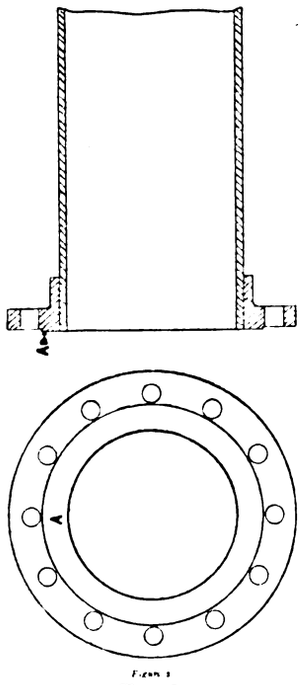

Fig. 2.

separators as it collects there, especially in view of the difficulty experienced in ascertaining the quantity of water in the separators, except by the use of gauge glasses, which are a source of constant trouble owing to the difficulty of getting glasses to withstand the pressure when there is any variation of temperature, or when they are subjected to sudden cold draughts.

The connecting pipes from the boilers to the main steam pipe, and from the main steam pipe to the engines, should be preferably of copper, with full swan neck bends to keep the water back as much as possible, and to allow of expansion.

Steam Traps.

These are most necessary adjuncts to the steam pipes; but although there are some very good steam traps on the market, probably most engineers will agree than an ideal trap has yet to be discovered.

All steam traps require a certain amount of attention, and should be fitted with a reliable class of stop valve to enable them to be shut off from the live steam main for inspection, and for the renewal of the valves and seatings when necessary.

Most of the modern traps will discharge at a considerable height, depending, of course, upon the steam pressure, and it will be found that a quantity of excellent feed water may be collected by this means.

When discharging to a height, each trap should be fitted with a non-return valve to prevent the column of condensed water in the pipe returning to the trap. It will be found convenient to group the discharge pipes from a number of steam traps into a small tank, having an overflow pipe to the hot well. This will enable the discharge of every trap to be inspected, which is a necessary precaution to ensure that each is in proper working order.

Valves.

Valves are a very important part of a steam system, and care should be taken to select a class of valve suitable for the work which it has to perform.

Full way valves possess so many advantages over other types, that in the most modern plants these are almost wholly used for high pressure steam work, and can be obtained from the smallest to the largest size.

The large valves on the main steam ring should each be provided with a small by-pass valve to enable a length of cold steam pipe to be warmed up, and the pressure balanced before the main valve is opened. This will prevent the straining of the joints caused by sudden expansion, and likewise accidents due to water hammer.

When erecting new steam pipes, attention should be given to the thorough cleaning of the pipes, as otherwise fine particles of grit, driven by the steam into the faces of the valves, cut into the seats, causing considerable trouble and expense. The author was informed by one large firm of valve makers that, owing to the trouble they had experienced from this cause, and the expense to which they had been put, due to the necessity of taking down and refacing valves fitted in this manner on new pipes, they intended in future to include in their estimates a certain sum to cover such cost.

Digitized by Google

Where, as is almost universally the case, boilers are run in parallel, it is advisable to fit a self-acting valve between the steam ring and the main stop valve on each boiler, the self-acting valve being placed immediately after the stop valve. There are various types of this valve, the usual form being a ball working on an inclined plane. The object in all cases is to provide a valve which shall close automatically when the pressure on the boiler it controls falls below that in the steam ring, as this enables that particular boiler, when thus isolated, to recover itself and to get up a full head of steam, upon which the automatic valve reopens, and again connects the boiler to the steam main.

Blow-Off Valves.

Where the boiler blow-off valves discharge into one common pipe as is usually the case, it is very necessary that the blow-off valve should be of some type in which the handle shall be practically locked when open. This will prevent the blow-off from a live boiler being forced into a boiler which is standing off for the purpose of being cleaned. Want of attention to this precaution has been the cause of many accidents, frequently involving the death of the men working in the boilers.

This locking arrangement is usually carried out by the use of some special form of key, in which the key is held locked in the valve as long as the valve is open, and can only be withdrawn when the valve is shut; and as long as one key only is available, it is, of course, impossible for two valves to be open simultaneously.

As, however, a key is supplied with every valve, the spare keys, which it is advisable to keep in case of breakage, should be locked up, in charge of one of the engineers, and should not be available in the works.

The author remembers seeing on a battery of boilers, which had been carefully fitted with this class of valve, two of the blow-off valves open at one time with, of course, a key to each valve, entirely doing away with the element of safety, and further causing this false feeling of security to become an added danger.

Where the blow-off from the flooding valves of super-heaters are led into the same blow-off pipe, and when, as is usual, a type of two-way valve is used which cannot be fitted with a locked key, possibilities of accident are averted by making a stringent rule that the flooding valves must not be opened unless the key of the boiler blow-off valves is hanging within sight.

Check Valves.

The check valves of boiler feed pipes are more convenient, for the purpose of inspection, when fitted with an arrangement which allows the valve and seating to be inspected while the boiler is under steam, and the author would also suggest the convenience of fitting every feed branch with a plug-cock, having a removable handle, to enable each check valve to be shut off for inspection both from its own boiler and from the feed main.

A plug cock with removable handle is recommended in place of an ordinary wheel valve, as the latter may be accidentally closed, whereas the handle would be fitted to the former only for the specific purpose of examining the check valve or for completely cutting off the water supply from a boiler when standing off.

The feed supply would, of course, in all cases be regulated by means of the check valves themselves.

Perhaps the author may be permitted to say a few words on the subject of feed water supply.

A convenient arrangement is to connect the pump suctions through suitable pipes and valves to the hot well, the cold well, and also to a third supply in case of emergency, and to connect the discharge pipes from the pumps to a double line of piping supplying the feed water either through the filters and one or more economisers, or if required direct to the boilers.

In the accompanying diagram fig. 3, A A A are the feed pumps, B the

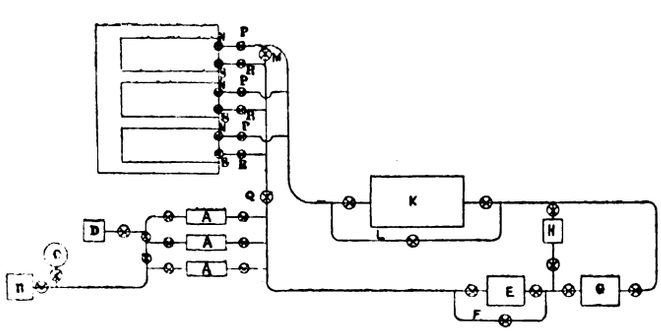

Fig. 3.

hot well, C the cold well, D the tank connected to a third supply, E is a cloth filter with by-pass F; G a sawdust filter fitted in series with E, with a by-pass sawdust filter H, the by-passes being used when the main filters are being cleaned. This arrangement has given excellent results, leaving the boilers clear of all traces of oil, which formerly proved a source of considerable trouble and anxiety.

The condition of the sawdust in G and H is a good indication of the condition of filter E, and proves whether or not it is doing its work properly.

K is the economiser with by-pass L, to enable it to be inspected and cleaned without passing the feed direct to the boilers *viâ* Q, which would entail cutting the filters out of circuit.

The arrangement of the branches from the hot and cold feed, enables the boilers to be fed either with hot or cold water through the stop cocks and check valves P N or R S, and by opening valve M, cold water can be fed through the hot feed check valves, or the reverse, should any of the branch pipes or check valves be out of order.

Pipe Covering.

A few words must be said with reference to the various coverings in use for preventing radiation of heat from steam pipes.

It is most necessary that all pipes carrying steam should be enclosed in a covering of some non-conducting material.

Endless varieties of pipe coverings exist which may be divided into two classes, permanent coverings and removable coverings.

The former, which are generally wrapped with some description of linen or canvas, have a good finished appearance when coloured and varnished, but suffer from the disadvantage that the covering is destroyed when it is necessary to remove it from the pipe at any point, and the appearance of the whole length of pipe is spoilt in consequence.

Removable coverings are, on the other hand, as their name implies, specially made for the purpose of allowing free inspection of the pipe, but in appearance they are usually clumsy, and do not lend themselves to the neat finish of permanent coverings. It is also questionable whether, as a rule, they are such efficient non-conductors of heat as are permanent coverings.

It would take up too much time to attempt to describe the many varieties of coverings on the market. They are all manufactured from some good non-conducting material, such as asbestos, magnesia, slag-wool, or felt, and are put on either wet or dry.

There are also numbers of coverings which depend principally for their non-conducting properties upon an air space being left around the pipe.

Probably every engineer has been induced at some time to try various coverings, and, like the author, has possibly found a few good, many indifferent, and some distinctly bad.

There is no doubt that to obtain an efficient steam supply with a minimum of condensation every portion of steam carrying metal must be covered with a thoroughly good non-conductor, and where practicable all valves and flanges should be treated in the same manner.

This applies equally to the drain pipes, or, at any rate, to that portion connecting to the steam traps. For the sake of keeping down the temperature in the engine house it is generally advisable also to cover the exhaust pipes with some non-conducting material.

Much more might be said on the subject of pipe work, but the author trusts that what he has advanced will fulfil his expectations, namely, to produce a useful and exhaustive discussion on what he ventures to think is a most important portion of central station equipment.

ELECTRIC LIGHTING MACHINERY.

A wail goes up in the *Engineer* from time to time. These wails are recurrent in our revered contemporary, and appear to be coincident with periods of depression to which we are all at times subject. At such moments our contemporary becomes pessimistic but never forgets to write in thoroughly autocratic style. This time electrical machinery and electrical stations come under review. The ignorance of electrical facts is deplored. Engineers have tried to live up to the science of the dynamo by employing scientific many-jointed engines and boilers. They have been like the suburban family living up to the high æsthetic level of the blue teapot. We should prefer to have used the other simile which says something about living up to the blessed doctrine of total depravity, for to our mind this is rather what has been aimed at. Electrical engineers have themselves to thank for most of their troubles. They began wrongly by criticising the wasteful methods of the factory engineers, but this was because so many of them were not men of practice. They emerged from class-rooms and designed stations and plant with no margins. To make matters worse, they undertook the use of untried forms of engines and novel boilers, and taking them all in all they have made a very good job of getting 1,000 H.P. out of a 600 or 700 H.P. plant. There has been too much expected from plant, more from new devices than it was known could be got from old and proved machinery. Everything not absolutely new and fresh in design has been condemned as fossilised. The professor has had full sway. He has worked up from theory to practice, and has taught his pupils to do the same, and in crossing the borderland between theory and practice there is very much rough country, which has never been allowed for. We admit the theory has been false theory in that it has refused to take notice of experimentally determined facts. The theoretical men have been like the lawyer who, at a conference with a client in gaol, said emphatically, "they can't put you in gaol for this." "But," responded the client, "I am in gaol." So with the new school of engineers, they have theorised too much and worked with insufficient margins. They have harped so much on the high cost of land in London and they have crowded plant to such a narrow limit that the dismantled and breakdown stuff occupied more space than would have held other plant. Then, again, in the subversion of the entire design of steam plant, old established firms have been shut out of the market. Being busy on other work, these old firms have preferred to wait until there appeared to be some finality in design. So far, except that there seems to be a tendency to revert to older methods, there is no finality in view. We think that the most successful undertakings of the near future will be those in which the fever heat observable in so many electrical stations is replaced by a more leisurely appearance. We want engineers who have the courage to demand plant of more capacity, and managements which are prepared to give it.

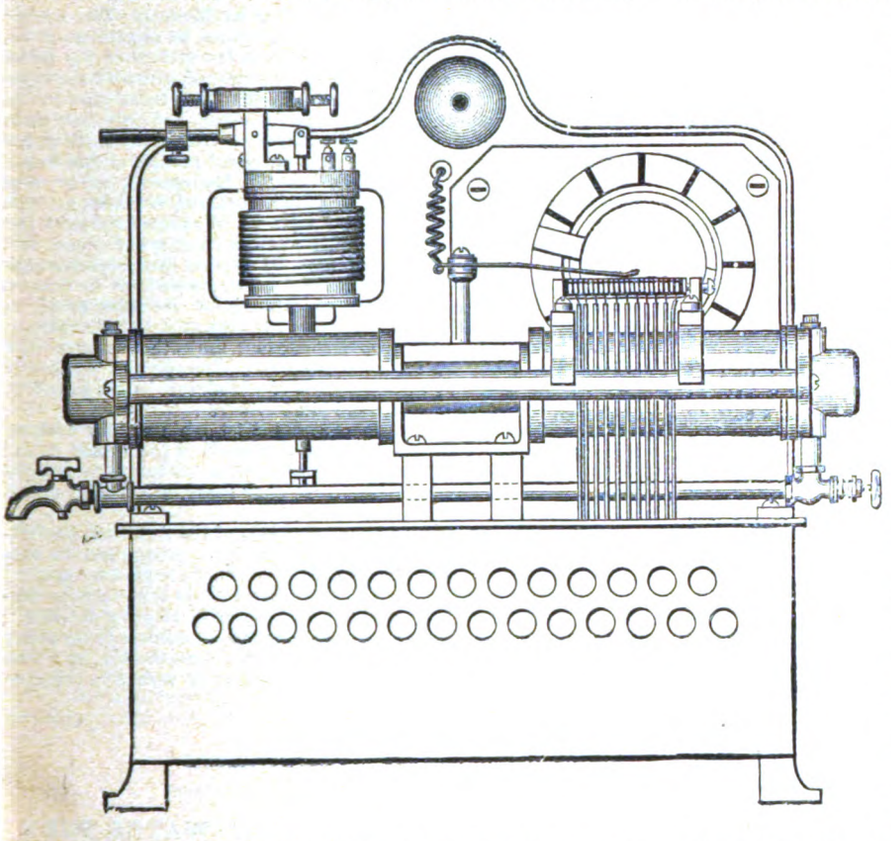
STEADY LIGHT FROM UNSTEADY POWER.

The economical and efficient operation of a plant of incandescent electric lamps involves the nice adjustment of two opposing factors which enter as items of expense. As one item is increased in any given case, the other is decreased, and *vice versâ*. These two factors are, on the one hand, the life of the lamps, and on the other hand, the power consumed in operating the lamps. The life of a lamp is favoured by making it a great watt consumer. A lamp using 4 watts per C P. has a much longer life, other things being equal, than a 2½-watt lamp, but the power used makes it expensive to use. On the other hand, the 2½-watt lamp, when subjected to fluctuations of voltage, becomes expensive in the item of lamp renewals. Close regulation is important for any lamp, but when the low-watt lamp is used it becomes an all-important factor in economy, and it is not infrequent to see in a lighting station one or more attendants constantly engaged in watching the voltmeter and operating a hand regulator as the changes of load or speed demand. The high-watt lamp is necessarily expensive in the item of power, and the low-watt lamp is also expensive in the item of lamp renewals when the regulation is poor; but the low-watt lamp, combined with perfect regulation, is the perfection of economy with incandescent electric lighting. Every electrical engineer fully appreciates this fact, and a good voltage regulator is the urgent demand of the times; this demand is claimed to be fully met in the Chapman voltage regulator, which Messrs. Laing, Wharton & Down, Limited, are now putting on the market. A large number of these are in practical operation, and have proved to be all that could be desired. A dynamo that has 750 4-watt lamps capacity can supply 1,000 3-watt lamps with the same amount of energy. The close regulation which can be obtained by use of the Chapman voltage regulator not only increases the capacity of the machines, but reduces lamp renewals, due to the constantly steady voltage.



The regulator is a magnetic device, and acts very promptly, being only limited in quickness of action by the ability of the generator it may be regulating to respond to change on a field resistance. The device is essentially a field resistance, whose operation is entirely automatic. The moving of the resistance switch is accomplished by the action of a working solenoid, and the actions of the working solenoid are determined by those of an auxiliary solenoid, which operates a set of contacts that control the admission of current to the sections of the working solenoid. The working solenoid is differentially wound, and is composed of four distinct coils, two of which have a small continuous current flowing through them in magnetic opposition to each other; the contacts close the circuit of one or the other of remaining coils, and so neutralise the action of one of the continuously acting coils.

This manner of connecting secures a rise of magnetism in the iron core of the solenoid whenever a break occurs at the contacts, and so avoids any injurious sparking at the contacts that would naturally occur by the magnetic discharge of the core. This arrangement completely neutralises the induction discharge, and no induction spark can occur. All the usual objections to contact points are therefore entirely removed, and they may be set very close to secure the most sensitive adjustment of the apparatus.

The entire work of the auxiliary solenoid is to move a lever arm with contact attached through a short space of, say, $\frac{1}{32}$ inch, and a very slight change of voltage is sufficient to do this. It is often desirable to have the voltage at the generating station rise a little with the load, so that it becomes greater than the voltage at the distributing point or end of feeder, where it remains constant with changes of load. This result is aimed at in the compound winding of generators, but in most cases is far from securing the result desired on account of the changes of speed, which no compounding of the generator can compensate for. The compounding of the auxiliary solenoid, however, secures the desired result under all conditions of speed or load, and a plain shunt wound generator becomes just as effective as a compound wound generator. The use of the Chapman regulator enables the old style alternating current generators having no compound coils to do just as good work as the more modern ones. Many machines that have been discarded as out of date will again become valuable and equal to the best.

The same is also true of direct current generators. There are many old generators of the shunt wound type, that will become just as useful as the more modern built machines, and even more so, by the attachment of the voltage regulator to them.

As to the energy consumed in the regulator, it is so small as to be negligible. The operation of the large working solenoid only requires the use of 60 to 70 watts of energy, and the resistance part of the device is concerned only with the current in the shunt winding of the generator which, as is well known, is only a very small percentage of the output of the machine. For instance, the regulator may be operated on a machine of 150 KW. with an expenditure of energy not exceeding ¼ H P.

The Chapman voltage regulator for varying speed dynamos solves a question of enormous importance to users of electric light. Central station engineers know the importance of unvarying voltage. It is simply out of the question to think of satisfying the general public without an almost absolutely steady light, and there is no way of doing this except by means of some kind of a regulator outside of the generator itself.

The Chapman voltage regulators are applicable to either alternating or direct current, and every plant subject to frequent changes of load and consequent change in voltage, run either by engine or water power, should have them. Their cost is slight compared with advantages gained by their use.

Several direct current machines connected in multiple may be controlled with one regulator, as well as though a regulator were used for each machine, but require special construction and must be so ordered.

Mills and factories can run light plants from their main line shafting without the necessity of special engines, even if there is a variation of 50 per cent. in the speed above the normal, and be assured of a steady light, a fact that could not possibly be accomplished by any other means without enormous loss by burning out lamps many times exceeding the cost of one of these regulators in a very short time.

They are claimed to do automatically what would otherwise require the constant attention of one man.

The size of the No. 1 style is 36 × 17 × 8 inches, and the weight is about 250 lbs. No. 2 is less highly finished, and is not enclosed with a plate glass front.

THE PROPERTIES AND APPLICATIONS OF ALUMINIUM.

MM. Ditte and Moissan have recently contributed to the French Academie des Sciences important papers on the above subject. Owing to the gradual extension of the field of utilization of this metal, we think these papers worthy the attention of our readers, and we therefore present abstracts of them below:—

THE PROPERTIES OF ALUMINIUM.

A. Ditte. *Comptes Rendus.* January 23rd, 1899.

In a previous article the author had proved that aluminium is readily attacked by many re-agents, and that its apparent stability is due to a thin adhesive film of alumina (Al_2O_3), or of gas. When the solvent used is one capable of dissolving alumina, corrosion occurs rapidly, since the protective coating is being continually removed. The presence of oxygen or of carbonic acid is required in order to provide the necessary supply of oxygen. In sea water, the same re-action occurs, the carbonic acid of the air being in this case the oxidizing agent. In the water of the Seine itself, aluminium is slowly corroded, the action being most marked at the point where the air and water meet. In either case, the attacked metal covers itself with a film of alumina, which may retain particles of other salts. If these impurities are allowed to remain in contact with the aluminium, the attack will slowly continue, and the metal will become disintegrated, even after removal from the water. To prevent this, it is necessary to wash the aluminium when taken from the water, with a

Digitized by Google

solution capable of removing the last traces of alkaline matter from its surface. The "sickness" of copper investigated by M. Berthelot, is a similar phenomenon to this progressive disintegration of aluminium. In the case of copper, the successive formation and decomposition of a small amount of cuprous oxide is the cause of the evil; in the case of aluminium a similar series of changes of aluminium hydrate brings about disintegration and decay.

THE PROPERTIES AND APPLICATIONS OF ALUMINIUM.

A. Ditte. *Comptes Rendus.* March 27th, 1899.

The author states that two qualities of aluminium were employed in his experiments. The first was sheet metal used for the bodies of bowls, plates, saucers, saucepans, measures, &c., and contained 96 per cent. aluminium, 3 per cent. copper, and 1 per cent. of iron, silicon, carbon. The second grade of metal was used for the rings, links, handles, &c., of the above articles, and contained 93 to 94 per cent. aluminium, 5 to 6 per cent. copper, and 1 per cent. of iron, silicon, and carbon.

These alloys, if maintained for a short time at a red heat, and then plunged into water, change in physical structure. They become granular, and the surface of the metal is found to be covered with fine cracks.

If immersed in a 2 per cent. solution of sulphuric acid, the action of the acid is more intense when pre-heating has occurred, and the surface of the metal covers itself with a black deposit of copper.

A 2 per cent. solution of an alkali carbonate, or a solution of common salt containing 8 grams NaCl per litre, rapidly attacks these alloys of aluminium at the ordinary temperature, and a coating of aluminium hydrate, $Al(OH)_3$, is produced upon the metal. If a polished plate of the metal be immersed in either of these solutions, it quickly loses its polish, and becomes coated with a thin film of crystalline alumina.

The effects of similar action are seen in the aluminium vessels, &c., returned from Madagascar. A piece of aluminium plate, a fragment of a portable water-tank, had its external surface practically uninjured, while its interior surface was found to have undergone physical change and to have become lamellar and fragile. Under the microscope it was seen to be strongly corroded and to be covered with aluminium hydrate.

This inner surface of the plate was more rapidly attacked by sulphuric acid and sodium carbonate solutions than the outer surface, and a metallic crystalline powder was detached. If a thin aluminium sheet be immersed in distilled water, the latter will gradually become alkaline owing to the transfer of small quantities of aluminium hydrate, sodium and chlorine, from the metal to the water; and the combined action of air and of water, containing possibly chlorine salts in solution, had no doubt *started* the disintegration of the inner surface of the metal used for these water tanks. Once begun the action would be self-supporting.

All the other Madagascar articles examined by the author (plates, measures, saucepans), showed signs of similar disintegration. The action of water and air on the cooking vessels was probably intensified by the materials cooked in them. The E.M.F. set up by the different solubilities of copper and aluminium would also assist the attacking agents, and accelerate disintegration. In sea water a copper aluminium couple gives an E.M.F. of between ·486 and ·525 volt.

THE APPLICATIONS OF ALUMINIUM.

H. Moissan. *Comptes Rendus.* April 10th, 1899.

The author states that Ditte regards the results obtained in his experiments as relative to pure aluminium, whereas his analyses show that the metal used by him was not first grade aluminium.

The metal produced to-day at the works of Heroult and of Secretan is almost pure, and contains neither sodium nor carbon. Tests are giving showing that while in 1893 the purest grades of aluminium obtainable contained between ·93 and 1·64 per cent. silicon, and between ·32 and 1·66 per cent. iron, the corresponding percentages of these two impurities in the metal of the present date are ·02 to ·13 per cent. silicon and ·12 to ·32 per cent. iron. This improvement in quality is chiefly due to M. Secretan's modifications of the Hall process.

The water tanks used in Madagascar were mounted on iron, and this fact explains their corrosion. As a set-off to the statements by Ditte that all the aluminium articles used in Madagascar which he has examined are corroded, Moissan states that he has seen numerous articles from that campaign which are practically unattacked, although bent out of shape and blackened with use. (Some of these articles were exhibited at the Academie des Sciences.) The state of the articles examined by Ditte may be due to their having been in contact with sea water in the hold of the vessel in which they were returned. Quotations are given from reports by regimental officers, all in favour of aluminium for camp outfits. The advantages of the metal for military service, as compared with tinned iron, are:—

1. Lightness; each soldier can carry 800 grams weight extra of ammunition.
2. No poisoning occurs from defective tinning.
3. No soldering of the vessels is required, as these are stamped out of sheet metal.

As regards Ditte's tests made by heating the metal and plunging it into cold water, such treatment would destroy any tinned iron utensil. The author has used aluminium in his own household for cooking purposes for three years, and these vessels are still in good condition; nor do they owe their preservation, as suggested by Ditte, to a protective coating of grease and dirt. A large hotel in Paris has a similar experience of one year with aluminium cooking utensils.

The advantages of aluminium may be summed up as (1) lightness; (2) an innocuous oxide; (3) capacity for being stamped.

The author closes by hinting that had M. Ditte lived in another age, he would have been found condemning iron, on account of its readiness to form an oxide and to rust on exposure to the air.

THE APPLICATIONS OF ALUMINIUM.

A. Ditte. *Comptes Rendus.* April 17th, 1899.

A reply to the previous contribution by Moissan. The author states that he has taken note of the impurities in aluminium in his experiments. These impurities remain on the surface of the metal when it is attacked, and by breaking the continuousness of the layer of gases, they render the metal more liable to disintegration. In the course of his investigations he has examined not only the lower grades of aluminium, but also aluminium produced by M. Secretan in 1899, *i.e.*, the purest offered as a commercial product at that date.

With regard to the water-tanks used in Madagascar, copper was purposely used to strengthen the metal employed for these, and the results of his examination of the returned fragments confirmed the results of his laboratory experiments with such alloys of copper and aluminium. The vessels exhibited by him at the Academie des Sciences were not returned in the hold of a vessel, or in contact with sea water; for no traces of chlorine or chlorides could be detected on their surface. M. Moissan has presented to the Academie articles from Madagascar in good condition; the author has presented others that show considerable corrosion. The obvious conclusion that should be drawn is, that vessels of aluminium have a long or a short life, according to usage and circumstances.

The author has not made personal trial of aluminium cooking utensils, but has used forks and spoons made of the metal. These were washed daily with a solution of sodium carbonate to remove the grease, and under this treatment they speedily lost their polish and became pitted and rough.

All the articles exhibited to the members of the Academie (including those exhibited by M. Moissan) have been greasy, and to this layer of grease some of them undoubtedly owe their preservation.

The author agrees with Moissan when he says that "chaque application de ce metal demande une étude speciale, longue et delicate"; and states that he himself has recommended aluminium to the army authorities as the most suitable metal for water-bottles, and has suggested improvements in the design of such vessels, in order to facilitate their mechanical cleaning.

FORCED CIRCULATION IN WATER-TUBE BOILERS.

When that foolish and extravagant experiment was made of putting flatly-inclined water-tube boilers into our big cruisers, the *Engineer* joined in the general acclamation. Recently, however, a leader appeared, which stated practically that it was impossible to expect such tubes to endure. It is pointed out that the tubes next the fire in a water-tube boiler are exposed to fierce heat from end to end, and must often be full of steam in place of water. The very small inducement to circulation which exists in a steam boiler is insisted upon, and the necessity of using larger tubes near the fires and providing free outlets at their upper ends.

We have long insisted on the folly of flatly-inclined tubes. Any tendency of steam bubbles to rise is reduced in a ratio corresponding with the sine of the incline. An inclination of 12° reduces the effect of gravity nearly five-fold. If water-tube boilers are to be a success, the tubes must be of necessity shortened down to a certain limit. Twenty-five diameters is the maximum allowed by the *Engineer* to be possible without bending effects being observed when under fire. Up to this length self-circulation seems to be efficient, or fairly so. It is all a question of water supply, and as we have before pointed out, the provision of a centrifugal circulating pump to draw water from the steam drums and force it to the tubes offers an apparent solution. Such a pump would simply be worked in a closed cycle. It offers no practical difficulties. The system is already at work in many industrial establishments. It is a large boiler which evaporates 600 gallons per hour, but it is a small pump which circulates 600 gallons per minute, and a very small expenditure of power would compel the circulation of water many times the volume of the evaporation.

It would not be difficult to so arrange matters that the lower tubes secured the larger supply. In the Belleville boiler the continuity of the tubes in vertical series demands such a system. Marine engineers accustomed to the use of circulating pumps for their surface condensers, might surely be expected to adopt similar means in the far more important matter of boilers. Until they do so, such boilers as the Belleville with flatly-inclined tubes and tubes in series cannot be considered safe even if made with solid drawn tubes. The serious bending of the tubes in the Belleville boiler is in itself sufficient to call attention to some serious internal trouble being present. Tubes full of water are not likely to bend in the most severe heat. The cooling effect of the water is so far and away beyond the absorbtive action of the external surface of the tubes in the fire that tubes would not become over-heated if they had a rapid current of water flowing inside them. Because such tubes may sometimes give way, and not kill half a dozen stokers, appears nowadays to be a sufficient justification for their use. But the tubes in water-tube boilers do not always produce small effects when they burst.

Digitized by Google

The Howard safety boiler killed many men, and so have others. Probably all the accidents of any moment which have happened to water-tube boilers have been due to over-heating due to want of water in the lower tubes. A forced circulation of sufficient amount would prevent such failures. Let us suppose a circulation of ten times the weight of water evaporated. On this basis how much of a tube would be occupied by steam and how much by water? Assume a pressure of 165 lbs. absolute. The relative volume of steam and water at this pressure is approximately 140 : 1. As only one-tenth is assumed to be evaporated, it is obvious that in a length of 14 inches of pipe only 1 inch is solid water. If the evaporation of the lower tubes is assumed to be double the average of the whole tubes—a moderate estimate—then only $\frac{1}{28}$th of the length of a tube is filled with water at the point where the tubes discharge to the headers. Treble the amount of circulation and this will be reduced to about $\frac{1}{10}$th. Now a tube must either be filled with foam of a specific gravity of about 0 10, or with alternations of water plugs and steam. A pipe of 4 inches will perhaps allow water plugs to exist 4 inches in length. Then the steam spaces will be 36 inches long.

If we have not made some error in the above calculations and assumptions, and, as regards the latter, we think we have understated, rather than overstated, unfavourable facts, it would appear that in the lower tubes of a water-tube boiler the bulk of water present is one-tenth that of the steam when the total circulation in the boiler is 30 times the evaporation. This means that all the water in a boiler must make a complete circuit every two minutes. We do not say that this would ensure safety; we do not say that more than this is not already secured by the natural circulation in the boiler. It may be that we underestimate the circulation which actually takes place. But we do not think we err in stating that whatever may be the facts, more circulation is necessary than is so far secured. We have, therefore, made the above simple calculation to fix certain ideas, and to point out how very little water can be present.

We might even go on to show that with a circulation of 1,000 per cent. of the evaporation, only 1 inch in three would contain a plug of water. As steam is not a good cooling agent, the cooling effect on tubes, if any water in them, is reduced in proportion as the amount of water is reduced. The fact that tubes show signs of overheating is, we take it, indisputable evidence that very little water is present. Seeing also that upper tubes do not suffer, it would seem desirable to leave the circulation in these to be accomplished naturally, and employ all the circulatory effort of the proposed pump to compelling circulation in the lower tubes.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Several excellent papers were presented at a recent meeting of this Society. One on "Boiler and Furnace Efficiency" may be quoted with advantage. It was presented by Messrs. R. S. Hale and W. B. Russell. They say the furnace should be roomy, and it should be brick-lined so as to secure a high temperature. Especially when the coal is poor should these points be attended to, and air leakage beyond the furnace must be particularly guarded against. These are points to all of which we have repeatedly called attention. The authors go on to say that a combustion of at least 15 lbs. of coal per square foot of grate must be secured when the boiler is doing its normal rating. Here, again, the advice is sound, as also is that to keep the evaporation per square foot of heating surface low.

Certain water-tube boilers suffer from air leakage, but the Thorneycroft boiler is highly spoken of. The Lancashire type of boiler is said to suffer from air leakage also, and it has a poor type of furnace. The furnace is the weak spot of the Lancashire boiler as regards its environment. Hence we say the boiler should be large, and we should expect rings of firebrick to help combustion. Mechanical stokers are not necessarily coal savers, but they may save labour and they may prevent smoke. They may also enable poor coals to be usefully burned. Down-draught grates have shown some good results, but too few tests have been made for final conclusions to be drawn.

A paper by Mr. Henning on "Boiler Explosions" was a plea for testing the materials of a boiler after a long period of work and after it had failed by explosion, from excessive pressure. Overheating produces the typical steel blue rustless scale, brightest at points where the heat has been greatest. Tests of such plates will show up the changes produced by overheating. The yield point will be low, the elongation large, as a rule, and the fracture will be altered in appearance. Overheated plates may be tested against strips of the same plate, cut and polished and overheated to redness at one end in a clear fire, then allowed to cool to a blue heat and quenched. Nicked at points where a change of colour occurs, and compared with the strips cut off plates overheated in the boiler itself, the fracture and colours will be a guide to a correct comparison, and the temperature may be estimated and conclusions drawn as to the behaviour between stay bolts. Generally, by carefully considered comparative tests, much may be learned. Mr. Henning endorses the opinion of English boiler experts that fair working conditions have never been proved to cause any deterioration of the quality of boiler plates. The bad condition of the plates in an exploded boiler has often, however, been used by the maker of the boiler to justify the contrary, probably a slight confusion of cause and effect.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1899.

Compiled expressly for this journal by W. P. Thompson & Co., Electrical Patent Agents, 322, High Holborn, London, W.C., and at Liverpool, Manchester and Birmingham, to whom all inquiries should be addressed.

15,169. "Improvements in electric storage battery plates." R. Kennedy. Dated July 24th.

15,178. "Improvements in the brushes of dynamos." F. J. Chaplin. Dated July 24th.

15,189. "Improvements in rail bonds for electric railways." F. H. Daniels Dated July 24th. (Date applied for under Patents, &c., Act, 1883, Sec. 103, April 25th, 1899, being date of application in United States.) (Complete.)

15,194. "Improvements in galvanic cells." W. B. Barry. Dated July 24th.

15,203. "Improved electric elevated railway." L. J. Bruns and H. R. Ottesen. Dated July 24th. (Complete.)

15,210. "Improvements in electric arc lamps." F. G. Chagnaud. Dated July 24th. (Complete.)

15,219. "Improvements in spring motors." E. R. Rogers and J. F. Cushman. Dated July 25th.

15,268. "Improvements in electric lamps." The British Thomson-Houston Company, Limited. (E. W. Rice, jun., United States.) Dated July 25th. (Complete.)

15,309. "Improvements in insulating electrical conductors." W. W. Colley. Dated July 25th.

15,335. "Improvements in tubular conduits for electric wiring" T. Taylor. Dated July 26th.

15,343 "Improvements in electric telegraphs." E. W. Smith. Dated July 26th.

15,359. "An improved primary battery for generating electricity." C. H. Preston. Dated July 26th.

15,365. "Improvements in electromotors." N. Popoff. Dated July 26th.

15,369. "Improved arc lamp having two arcs in series." W. Mathiesen. Dated July 26th. (Complete.)

15,370. "Improvements in secondary or storage battery." T. de Michaelowsky. Dated July 26th. (Complete.)

15,377. "Improvements in the insulation of armature plates in dynamo-electric machines." F. P. V. Leconte. Dated July 26th.

15,404. "Improvements in electrical distributing fuseboards for concentric cables." J. R. Weston. Dated July 27th.

15,407. "Improvements in apparatus for controlling electrically propelled trains." The Lancashire Dynamo and Motor Company, Limited, and A. P. Wood. Dated July 27th.

15,418. "Improvements in insulated electrical conductors or cables." H. Edmunds. Dated July 27th.

15,426. "An improved electric battery and process for constructing the electrodes for the same." A. Tribelhorn. Dated July 27th. (Complete.)

15,438. "A new or improved electrolytic process and apparatus for the production of chemically pure cupric sulphate and copper." E. Frenot. Dated July 27th. (Complete.)

15,440. "Improvements in electrolytic incandescent lamps." M. von Recklinghausen, A. Voor, and Nernst Electric Light, Limited. Dated July 27th.

15,460. "A new or improved tap-switch for electric incandescence lamps." G. Gardner. Dated July 27th. (Complete.)

15,467. "Improvements in switches for breaking electric contact." N. G. Knighton. Dated July 28th.

15,482. "Improvements in and relating to portable direct reading ohmmeters for measuring low electrical resistances." A. Jamieson. Dated July 28th.

15,525. "Improvements in electric switches." R. W. H. Hofstede-Crull. Dated July 28th.

15,541. "Improvements in dynamo electric generators and motors." C. W. Atkinson. Dated July 28th.

15,578. "A new or improved method of, and apparatus for, a combined system of electric light fittings and fire alarms, and for appliances connected therewith." C. C. Metcalfe. Dated July 29th.

15,581. "A combined switch and ceiling rose or other fittings for electric lighting purposes." S. Jevons and W. H. Lloyd. Dated July 29th.

15,583. "Improvements relating to electric cash register tills." W. Snelgrove. Dated July 29th.

15,599. "Improvements in or relating to electric switches and like apparatus for making and breaking electric circuits." G. W. Partridge and G. K. B. Elphinstone. Dated July 29th.

ELECTRICAL PATENTS OF 1885 EXPIRING IN AUGUST, 1899.

We are informed by Messrs. W. P. Thompson & Co. that about 76 applications for electrical patents were filed in the month of August, 1885. Out of these only one has been maintained to run its full length of term, viz., 14 years, and being of considerable interest, we give a short abstract below:—

9,527. "Improvements in Motors for electric railways." T. J. Handford. (F. J. Sprague, United States.) Dated August 10th, 1885. Motors for locomotives. The electro-motors are so arranged that the relative positions of the armature and field magnets will not change, and are so supported that any movement of the car body relatively to the wheels will not disturb the mechanical connection between the armature and the driving axle. The shaft of the armature is carried in bearings fixed to the pole pieces of the field magnets. At the centre of the driving axle are journals connected to extensions from the pole pieces, which maintain the armature at the same distance from the driving axle. The electro-motor is supported by springs from the body of the car, which may be adjusted so as to relieve the driving axle of dead weight to any desired extent. 3 claims.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson and Co., 322, High Holborn, W.C., and at Liverpool, Manchester, and Birmingham, price, post free, 9d. (in stamps).

1897.

17,528. "Improvements in spring jacks for telephone switchboards." J. E. Kingsbury. (The Western Electric Company, United States.) Dated July 26th, 1897. Jacks for telephone switchboards are constructed in rows. A strip of insulating

Digitized by Google

material has a row of holes drilled in from the front, and a row of smaller holes from the back, one edge of the holes from front and back being in line. Inclined duct holes are then drilled, and the necessary saw cuts made for holding the springs in position. The metal thimble is fitted in front, and has a shank which is secured in the duct. There is an inner spring thimble or tube having a shouldered shank which lies partly in the duct. There is a central spring for making contact with the tip of the plug, and is secured in saw cuts. The thimbles are riveted to the strip. The plug has two metal sleeves to engage with the thimbles, and a central metal core. 6 claims.

17,540. "Improvements relating to electric light fittings." H. Lea. Dated July 26th, 1897. Several incandescent lamps are carried by holders on arms of a central support which is hung by a twin conductor from a ceiling rose. A translucent china bowl is suspended below the lamps by hooks and cords from the ceiling rose so as to be readily removable for cleaning. The cords pass through eyes on a body, which may be raised or lowered to adjust the height of the bowl relatively to the lamps. 2 claims.

17,546. "An improved electric circuit-closing device." C. A. Holistein. Dated July 26th, 1897. The falling weight of, or operated by, an alarm or other clock or mechanism is arranged to complete the circuit between the contacts at a predetermined time. 1 claim.

17,597. "Improvements in and connected with conductors for electric railways." W. L. Wise. (A. Skrotz, W. P. Allen and O. S. Kelly, United States.) Dated July 27th, 1897. Relates to electric railways and tramways on the third rail system. The conductor is of angular section. In another form is rubbing surface for the collector, or it may be of other sections. It is mounted on insulating posts or insulators on the sleepers or guard rails, and is covered and protected by the covers and side shields supported on the insulators or conductors so as to leave a passage for the collector between the side and the guard rail. The side pieces may be omitted, and the parts may be duplicated for a return circuit. 10 claims.

17,609. "Improvements in or relating to electric furnace." I. L. Roberts. Dated July 27th, 1897. (Date applied for under Patents, &c., Act, 1883, Section 103, December 29th, 1896, being date of application in United States.) A sheet-iron casing provided with a hopper and a flue covers a travelling band which is carried by rollers, and is preferably of cloth woven from wire covered with asbestos. Two electrodes are carried in asbestos packed ball joints in the closed end of the casing, and are bolted adjustably to stationary curved slotted plates. They may otherwise extend downward into the casing, the ball joints being placed in the top of this, between the hopper and flue. Powdered materials are fed in by the hopper, and the electrodes, after being in contact at their ends, are gradually separated until they are parallel, or an arc may be started by placing pieces of carbon between the electrodes. The belt is slowly moved forward, carrying with it unacted on material enclosing a continuous layer of the product of the furnace. This may be delivered in the fused state, if the furnace is short, or otherwise may be broken off in lumps at the end of the furnace. The furnace is applicable for the manufacture of calcium carbide and carborundum, and for other purposes. 11 claims.

17,678. "Improvements in coin-freed electricity meters." W. Emmet. Dated July 28th, 1897. A beam is balanced so as to remain tipped up in the direction shown after a coin has struck the pan at one end, and to tilt in the opposite direction when liquid or sand from a hopper fills the vessel at the other end. In the first position the electric circuit is completed through a pair of upright contacts. According to the strength of the current used a solenoid attracting a lever sets a cam so that the valve of the hopper passes a proportionate quantity of liquid or sand. In the second position the beam completes the circuit with the pair of contacts so that the current passes through an impedance or resistance which reduces the light. 2 claims.

17,694. "Improvements in and connected with electric lamps for cycles and other vehicles, and a device for attaching and adjusting same." J. Moores and H. O. Farrell. Dated July 28th, 1897. A generator for use on a cycle or other vehicle consists of a permanent field-magnet, and preferably a shuttle armature, enclosed in a casing which is supported adjustably by an angular rod and clamps on a fork so that a friction wheel on one end of the armature shaft engages the inside of the rim of a wheel of the vehicle. The casing may support an electric lamp. The friction wheel may be wholly of India-rubber, or may be a metal pulley carrying an India-rubber ring; the India-rubber may be roughened or contain emery to improve its grip. 8 claims.

17,696. "Improvements in and connected with armature cores of permanent magnet dynamo-electric machines." J. Moores and H. O. Farrell. Dated July 28th, 1897. Relates to armatures. An armature core for permanent magnet dynamo-electric machines is built up of two strips of sheet iron, bent over at both ends and fastened together back to back, so that the bent portions together form arc-shaped pole faces. The radial parts may be narrower than the pole faces in which case stiffening plates are added. 1 claim.

17,733. "An improvement in incandescent electric lamps." T. D. Farrell. Dated July 28th, 1897. Relates to incandescent lamps. One or more filaments are arranged with parts conveying opposite currents placed as near together as possible. For this purpose, a filament may be doubled at the middle and wound into a flat spiral, with its ends either at the centre or outside; or it may be formed into a cylindrical or conical helix, and provided with a rod to support the middle of the filament. 4 claims.

17,812. "Improvements in electric railway systems." J. M. L. Murphy. Dated July 29th, 1897. Relates to electric railways and tramways on the sectional conductor system with switches operated electro-magnetically or otherwise. Two grooved sectional rails convey current from a battery on the vehicle to the switch, which connects the main conductor to the exposed sectional conductor. The subsidiary current excites the magnets, which attract the armature, and complete the circuit between the main conductor, and the sectional rail, by the wedge-shaped contact piece and the spring contacts. The magnets are then included in the main circuit to keep the armature attracted until the circuit is broken at the rail, when a spring acting on the rollers on the T end of the pivoted armature restores it and breaks the contacts. The main collector consists of a piece with rollers. It is mounted on a slide, and connected to a pair of fingers which bear in the grooved subsidiary sectional rails. 15 claims.

17,820. "Improvements in the manufacture of electric cables and in apparatus therefor." W. S. Smith. Dated July 29th, 1897. Cables with co-axial helices of wire separated with insulating material are formed by supplying the wires from a twisting machine, having several bobbins mounted on a disc. The main shaft also drives a die-plate by means of bevel gearing. The die-plate and tube are mounted in an ordinary press chamber, and the covered cable passes out of a stationary die. 2 claims.

17,828. "Improvements in electric lanterns." O. C. Prasse. Dated July 29th, 1897. Relates to lanterns for bicycles and other vehicles. An incandescent lamp is screwed into a conical reflector, fixed on a metal battery casing and provided with a glass front. The casing contains two round cells with porous pots and screw covers, which carry hollow cylindrical carbons. Perforations into inclined recesses permit escape of gas from the porous pots, and mercury is placed in these recesses to prevent leakage, if the battery is tilted. Zinc rods are supported by central rubber plugs in the cover. The cells are connected in series through the casing with springs supported in the hinged lid of the casing, when this is closed, and by a disconnecting switch. The porous pots may be charged with dilute sulphuric acid, and the outer cells with a solution of bi-carbonate of potash, sulphuric acid, and bi-sulphate of mercury. 6 claims.

18,029. "An improved process for the manufacture of electrode plates for storage batteries." C. Marschmer. Dated July 31st, 1897. A material for binding the active material to the supporting grid or frame consists of amber dissolved in dichlorhydrin or epichlorhydrin and mixed with alcohol. Reference is made in the provisional specification to Specification No. 12,250, A.D. 1896. 2 claims.

24,833. "Improvements in and relating to electricity meters." J. Routin and C. E. L. Brown. Dated October 26th, 1897. Relates to quantity and energy meters. A current is periodically sent through an electro-magnet which causes a pawl lever to rotate a ratchet wheel to some extent, the lever being returned against a stop by a spring after each such movement. The ratchet wheel drives a counter. For measuring quantity or total energy, the stroke of the lever is limited variably by a cam, attached to the indicating spindle of an ampere or wattmeter. The cam is freed by the lever when this returns; a fixed stop prevents any action of the pawl on the ratchet wheel while the lever is lower than the lowest portion of the cam. For measuring the duration of current, the cam is replaced by a stationary screw. The periodic current is supplied to all the meters on a pair of supply mains, by connecting their coils between one main and an earth plate, a condenser being interposed if the main current is continuous. The main is connected with a source of continuous current, which is periodically connected to earth by a switch operated by a clock. The period may be altered at different times of day, in accordance with the load in the generating station. The source of current may be an exciter for alternators supplying the mains. When the supply of current is from a transformer, the source may be a dynamo driven by a small motor supplied from the mains. 4 claims.

25,307. "Improvements in or connected with drum armatures for dynamo electric generators and motors." V. A. Fynn. Dated November 1st, 1897. Armatures for continuous or alternating current generators or motors. A slotted drum armature, the slots of which certain several superposed conductors or layers of conductors, is wound in such a manner as to avoid all solder joints, except those at the commutator. The conductors are wound on without previously forming the spools or sections, and those portions which are situated outside the slots are symmetrically arranged, and contained between two cylindrical surfaces, one of which passes through the bottom and the other through the top of all the slots. The invention is described as relating to a four-pole machine, each slot being supposed to contain only four conductors arranged in two layers. The inside connections are those at the commutator end, and the outside connections those at the opposite end. Such an armature would have 17 slots numbered 1 to 17, and the step would be from slot 1 to slot 5, from 2 to slot 6, and so on. It will be seen that after the formation of the first section, the conductors forming the bottom layer of slot 1 are in connection with those forming the top layer of slot 5, the end connections being bent upwards from one layer into the other about half way between the two slots. The same applies to all the other sections. 2 claims.

25,396. "Improvements in switching gear for transformers, reactance coils, storage batteries, and the like." The British Thomson-Houston Company, Limited, and H. M. Hobart. Dated November 11th, 1897. Switches for transformers, resistances, storage batteries, &c., for obtaining a fine adjustment. The turns are connected alternately to contacts arranged in rows. Conducting bars are arranged between these rows, and connected by a resistance from the middle point of which a wire leads to the main. Bridge pieces slide along the bars and connect alternately with the contacts in the row. The contacts are carried by, but insulated from, a carrier fitted with a nut which is reciprocated when the screw is turned. 2 claims.

25,332. "Improvements in and relating to the jointing of electrical cables." H. E. Menier. Dated November 11th, 1897. (Date applied for under Patents, &c., Act, 1883, Sec. 108, May 11th, 1897, being date of application in France.) Telegraph and other cables have the insulating material placed over a joint, compressed, while cooling and setting. Two half-moulds are hinged along one edge by a rod, and are locked when closed by a rod on the other edge. Two semi-annular elastic bags fit the hollow of the mould, and leave a central opening for the cable. The bags are provided with tubular extensions into which the tubes are fitted. The extensions through which the tubes pass are closed by caps. Glycerine, water, air, &c., is forced into the bags to produce an even pressure on the insulation over the joint. The bags may be modified, leaving only the outer end portions, the insulating material itself being forced through the pipes. 3 claims.

25,333. "Improvements in and relating to telegraphic receiving apparatus." J. A. L. Dearlove. Dated November 11th, 1897. Receiving apparatus for submarine and other similar cables is arranged with the suspended coil connected to the cable and to a pivoted light lever means of threads. The lever is connected to an influence machine, such as a mouse mill or to the secondary of an induction coil. The longer arm of the lever moves over the contacts, but is not in contact with them. Each of the stops is in connection with a separate coherer circuit, or two separate levers may be employed for receiving dots and dashes. The coherer may be of the filings form, or may be a partially-exhausted vacuum tube containing ball terminals. There is a relay in the local coherer circuit. The armature of the relay is in the local circuit including the recorder or translator. This local circuit also includes the decohering magnet, which may be a single stroke or operate an armature carrying serrated rods passing through the supports of the coherer. 5 claims.

25,389. "Improvements in electrical measuring instruments." G. K. B. Elphinstone and A. C. Heap. Dated November 12th, 1897. Current meters for alternating currents. A pivoted coil carrying a pointer or recording-arm, and controlled by a spring or weight is movable about a stationary soft-iron core between the ends of a laminated soft-iron magnet. This carries two sets of coils, disposed symmetrically to avoid magnetic leakage. One set carries the current to be measured, and may be in series with an inductive or non-inductive resistance if the instrument is used as a voltmeter. The other coils are connected with the movable coil by an adjustable inductive or non-inductive resistance. The coils magnetise the soft-iron circuit; a secondary current is induced in the movable coil circuit. The inducations are stated to be practically independent of the frequency and wave-form of the current. 2 claims.

25,412. "Improvements in electrical transformers." The British Thomson-Houston Company, Limited, and H. M. Hobart. Dated November 12th, 1897. Transformers are wound so as to allow free ventilation and also heavy insulation at the ends of the layers. Corner pieces are arranged at the corners of the core and then a few turns of bare copper strips to serve as the secondary are wound on. A ventilating space is thus left between the core and the coil. A layer of insulating material is then placed in position and the primary coils wound on, there being one or more fewer turns at the ends on each successive layer. The insulating layers project beyond the coils, and the insulation is thickened. Finally one or two layers of secondary may be wound over the primary. 4 claims.

25,441. "Improvements in the preparation of accumulator plates." C. A. Bennert. Dated November 12th. In making plates or electrodes, there is used lead oxide or lead peroxide prepared from white lead or lead hydroxide electrolytically formed such as by the process described in Specification No. 14,801, A.D. 1895. 1 claim.

25,468. "An improved memorandum desk for use with telephones and for other purposes." C. Harryman. Dated November 13th, 1897. Paper rolls are held in bearings in a bar by turn buttons, and are acted on by tension springs. The paper passes through a slot above and below a carbon sheet, between rollers geared together and actuated by a handle and under a cutter. One of the rollers is covered with rubber and is pressed upwards by a spring so that, by turning the handle the paper is drawn tight from the rolls. The cutter serves to sever the used paper. Only one roll may be used. The clips hold the transfer paper. 3 claims.

25,530. "Improvements in apparatus for heating buildings and the like by means of hot fluids or electricity." J. A. Dargue, E. Griffiths, and C. H. Wright. Dated November 13th, 1897. Radiators heated by fluids or by electric currents, are provided below with openings closed by flaps to admit fresh air. The heated air escapes by the grid above. A plate is provided to receive the dust deposited by the air. It is supported on centres or may slide in guides so that the dust can be easily removed by rotating or withdrawing it, or a scraper or the like may be employed to remove the dust from the plate. 2 claims.

25,540. "Improvements in electrical resistance apparatus." F. Hughes. Dated November 15th, 1897. An incandescent lamp is mounted as shown in section for controlling the supply of current to any apparatus, such as the lamp for examining casks, &c., described in Specification No. 8,135, A.D. 1895. The lampholder is carried by the non-conducting top of a perforated cylindrical metal casing which is fixed on a weighted non-conducting base and has a handle and a vertically sliding door. Four terminals, such as are provided in a groove in the edge of the base, two being connected to the lamp terminals, and the other two connected together. 2 claims.

ELECTRIC TRAMWAYS IN LONDON.

IT is but repeating an oft-told tale to mention that in many matters affecting the welfare, the comfort, and the convenience of the inhabitants, London occupies an inferior position to many, if not most, provincial cities. Not only are the arrangements of intercommunication lamentably old-fashioned, but the lighting of streets and open spaces is neglected to a remarkable degree, and it is not surprising that it should be held up to ridicule by intelligent foreigners. In an American city of moderate importance a swift electric tramway service provides the most popular mode of progression; in London, where walking is impossible, the traveller must use the slow and lumbering omnibus or endure the rapaciousness of a cab driver. There are, however, signs of an improved state of things so far as systems of locomotion are concerned; the districts of West London are likely to receive the benefits of an electric tramway service within a reasonable period, and even the London County Council is prepared to modify the views which it formerly held, and give us a system of electrically operated lines. Some time ago Prof. Kennedy was commissioned to prepare a report on the subject, and in many respects the report which he has presented to the London County Council is of the greatest importance. It is, in the first place, one of the few reports on electric traction prepared by an eminent English consulting engineer for a local governing body, and for that reason alone the conclusions which he has given should be weighed with the greatest care. For the purpose of arriving at a just appreciation of the various systems of electric tramways at present in use, Professor Kennedy has paid visits to the Continent and to America, and doubtless the information which he has obtained is of the greatest value. It is not proposed to make any extended reference or quotation from the report, for we print it full in our other columns. But in order that our comments may be appreciated at their true worth, it will be necessary to make an occasional reference to some of the statements which are put forward. The systems upon which the Professor has reported, comprise the use of gas, compressed air, and electricity. Most of our readers will probably share Prof. Kennedy's convictions that gas and compressed air cars possess unmistakable advantages in being self-contained, and independent of a central source of power. In this, however, they share their advantages with accumulator cars, but just as we should expect the exercise of caution in recommending the latter form of traction, so are we not surprised to learn that Professor Kennedy does not recommend either gas or compressed air, for the reason that there is not sufficient experience of compressed air traction, and gas traction is for the present put out of court by the difficulty in obtaining really suitable engines. Having, therefore, dismissed these systems as not possessing sufficient merit to be entertained by the London County Council, Professor Kennedy comes to consider the use of electricity.

Digitized by Google

No one could deny that the four systems of electricity, the overhead, the conduit, the surface contact, and accumulator systems have been carefully gone into. But a most casual perusal of the report soon convinces one that in the Professor's estimation the overhead wire system is practically unsuited to the condition of the central London streets, although for thoroughfares that approach the suburbs Prof. Kennedy is not averse to overhead wires. Coming after the completion of so many important schemes involving the use of overhead wires, the conclusions of Prof. Kennedy are, to say the least, somewhat startling, and it is necessary to carefully consider the whole position of electric tramways in this country, because the proposals of the County Council are watched with the greatest interest by many municipalities, and doubtless the system they adopt will be copied to some considerable extent. It will be admitted that the importance of the County Council's proposals are lessened by the fact that great municipalities, whose work is not one whit less useful than that of the County Council, have already embarked upon overhead wire schemes. In speaking of the overhead wire system, Prof. Kennedy states that when carried out as roughly as it has been carried out in America its cost is very much less than that of any underground system, but carried out as it is necessary to carry out a system in this country the difference of cost is not nearly so great. It will be necessary to refer to this point subsequently, but when it is stated that for this reason the overhead system has naturally commended itself to private tramway companies and also to municipalities in comparatively small towns, one feels constrained to point out that the overhead wire system, where adopted by municipalities, is not in small towns but in the great towns, Liverpool, Manchester, Glasgow, &c. In any one of these cities it can be confidently stated that the tramway systems are equal to, if not in some respects larger than that at present controlled by the County Council. There are probably many engineers who will be inclined to agree with the view that the overhead wires cannot be regarded as likely to prove a permanent and final solution of the traction problem in a great city like London. Admitting that, however, it must not be forgotten that some system may arise which will do away with the necessity of using overhead wires, and that such a system may also render obsolete both the conduit and the present forms of surface contacts. As Prof. Kennedy points out, crossings and street junctions on the trolley system do involve a little complication in overhead wires, but there are many instances in this country where the overhead wire work is of such a description that very little objection can be urged against it. Moreover, much of the complication which at present arises at such places is greatly enhanced by the use of guard wires. Guard wires for the most part, especially in large cities, are necessary to give protection to the telephone system, but the National Telephone Company which owns the whole of the town overhead telephone wires of the country is gradually putting its overhead net-work underground, consequently in a few years' time the necessity for employing guard wires may cease to exist. Moreover, if even telephone and telegraph wires were always to remain in contiguity to the tramway wires, we feel confident that some method would be evolved to obviate the use of somewhat unsightly guard wires. Professor Kennedy makes the statement that "If any private company asked permission from a committee of the London County Council to erect at any one of the 12 junctions, such arrangements of poles, span wires, stays, guys, conductors, &c., the proposal would be met by an absolute and unconditional negative." It is quite probable that Prof. Kennedy is right on this point, and we firmly believe that the County Council would refuse permission. In raising these objections to the overhead trolley system, it is obvious that Prof. Kennedy is paving the way to the suggestion of a conduit system; and it may be said that the chief part of his report is devoted to establishing the claims of an underground conduit or slot system. The Professor states: "I am glad, therefore, to be able to say as the result of my examination of the present state of underground electric tramways, that the laying out and working of lines on the slot system has already been carried out successfully on a very large scale." No one seeks to deny for a moment the conspicuous and well-deserved success that has followed the introduction in some places of an underground conduit. But there ought to be a clear and unmistakable understanding on the part of all persons engaged in considering the problems of electrical traction that the underground system has been only adopted where it has been made compulsory. The authorities that control the roads of our cities have perfect and free right to prevent what may be held as spoliation, but it must not be forgotten that in this country tramways will be for the most part operated and controlled by municipal bodies, and naturally, whether they carry out the system themselves or permit it to be carried out by a company, their concern for the appearance of the public thoroughfares is the same, and admitting that, what do we find? Nothing less than the wholesale adoption of the overhead wire system by the various large towns of the country. And lest there should be any misunderstanding on this point, we want to show that the great scheme of the London County Council is not the only one in the country; it is probable that the tramway system to be converted to electric working will comprise some 200 miles of single track and 500 cars, but the Glasgow Corporation have already decided to adopt a system taking 600 cars as a basis and with a mileage that will be probably greater than that of London. The Corporation of Manchester is at present engaged on a scheme that is of much more importance than that of the London County Council, Liverpool is going ahead with a large scheme, and these municipal authorities have considered that the overhead wire system is the only one to adopt. We have a certain amount of belief in a conduit system, and there is no doubt that from a working point of view it is quite as practicable as an overhead wire system. It may cost a little more to operate on account of the larger maintenance charges, but there is no shadow of doubt that such a system can be really considered on a practical basis. It must not be lost sight of, however, that a conduit system means a very serious increase in capital expenditure. If a local authority is prepared to pay for such a system it must be clearly understood that it will give no better working, and will be, moreover, open to certain drawbacks. Prof. Kennedy lays considerable stress upon the fact that the chief engineer of one of the principal companies using both systems gave as his experience, that where the overhead system has to be provided with underground feeders and with handsome poles and other appurtenances as would meet with the approval of his municipality, the actual difference in cost between the two systems was very inconsiderable. It is necessary that fuller information should accompany such a statement, because it has been fully recognised by engineers who have carefully considered this matter that there is a very considerable difference between the cost of

Digitized by Google

constructing an underground conduit and the overhead wire system, even where the overhead work has been of the very best type. One of the most notable instances of the conduit system is that of New York, and there is very little doubt that the commercial success achieved by this line has been due to the splendid way in which the conduit was built, which, moreover, cost as much as £20,000 per mile. It is interesting to quote from our issue of December 2nd, 1898, when we made some reference to the New York conduit system. We said then: "Supposing that the entire Metropolitan system of 210 miles should have been equipped on the best overhead system, instead of the conduit, a saving of 2½ to 3 million pounds sterling in the capital expenditure would have been effected." We further stated that it must not be overlooked that the construction of a conduit, besides at least doubling the total capital expenditure, entails an enormous amount of annoyance to a city during its construction, as the people of Brussels, New York, and Berlin now know to their cost. Before leaving this phase of the subject we would call attention to the views expressed by an expert of undoubted eminence in electric traction, and the opinions put forward by this engineer are especially interesting, because the New York conduit line, about which we have heard so much, was designed and carried out by him. We are referring to Mr. Pearson, who was called in by the Liverpool Corporation to advise on the subject of traction. At that time the municipality of Liverpool were in doubt as to the best system to adopt; but the opinion put forward by Mr. Pearson was clear and emphatic on this subject. He stated in his report to that municipality that "the cost of construction of the slotted conduit is very much greater than that of the overhead trolley, as it is necessary to build the conduit in a very substantial manner, in order to withstand the heavy trucking and the effects of frost, which tend to close the slot and disarrange the conduit."

One advantage possessed by the overhead wire system is, one pole will frequently serve to carry wires for two tracks; but with the conduit each track means a separate conduit, and this affects cost of construction in a most striking manner. Taking Mr. Pearson's estimate for Liverpool, we find that one mile of straight track for overhead trolley would cost £5,822, and one mile of straight track slotted conduit system £9,648. If we were to take these as a basis and apply them to the 200 miles of track in London, a conduit system for track alone would cost the County Council £1,929,600, against £1,164,400 for the overhead. In other words, they would pay £765,200 for the luxury of working tramways without overhead wires. We are quite aware that it is not proposed to apply the conduit throughout, still these figures serve to show how enormously the expenses increase over a large system. Very probably Prof. Kennedy has had in view the permanence of the system, but one may pay too high a price even for permanence. In considering electric tramways, we do not suppose there is a single municipality that has not been at the beginning prejudiced against overhead wires. The report of the Glasgow deputation states that "we started our investigations more or less in sympathy with this objection (to overhead wires), but we are bound to say that what we have seen has quite removed from our minds any objection to the overhead wires. Where the system is carried out in the most approved manner, we found that the wires gave only the very slightest offence." But even if the good citizens of Glasgow had prevented the introduction of the overhead system, they would have been completely debarred from using a conduit system, for on one of the principal routes the surface of the street is within 12½ inches, and at other places the arch of a bridge was only 4½ inches from the street surface; it will be seen that under those conditions concrete below the central conduit to a depth of 2 feet is quite out of the question. Is London in any better position than Glasgow in this respect? There may not be many bridges to cross, but the amazing ramification of pipe work within a few inches of the street surface should give pause to any conduit scheme. Why, the very section on which the County Council proposed to try the conduit system is declared by Prof. Kennedy to be unsuited, because along this route there are "three 30-inch water mains at no very great depth below ground." But if Prof. Kennedy and the Council is convinced that the electric conduit is the right thing, why try experiments? We know that the conduit can be made to work, and surely it is hardly necessary to acquire information as to management. Moreover, an experiment is being already carried out for the benefit of the London County Council, but at the expense of the London United Tramways Company. There is another point on which we should like to lay special emphasis. The Professor says: "While admitting to the fullest extent that for a company whose business is to earn dividends for its shareholders the overhead system will appear the most, advisable, and while admitting also that for small towns where the traffic cannot be anything like as much as, and where the expenditure may be proportionately much larger than in London, it may be desirable, on public grounds, to limit the expenditure to the lowest possible amount, yet in the case of London itself I submit that these considerations have not such weight." Our contention is that it is not the small towns which have adopted electric tramways, but the large ones. It must be admitted that the central portions of Liverpool and Manchester are almost as crowded as London, yet we find that the Liverpool Corporation, after a deputation had inspected the European conduit systems, reject the conduit because it "is unsuitable for Liverpool tramways with their heavy and crowded traffic"; they share with the Sheffield municipality the view that complicated tramway crossings would entail considerable constructive difficulties, the system is expensive to maintain, and liable to interruption; that in case of breakdown the difficulty of access causes serious delays; moreover, the Liverpool Corporation states that from a sanitary point of view an open conduit which cannot be effectively cleansed is objectionable. The Belfast Corporation are possessed of a praiseworthy desire to preserve intact the beauty of their streets, yet a committee declares that "the difficulties that would be encountered in introducing an underground conduit system in the lower portions of Belfast, having regard to the position of sewers, covered river courses, gas and water mains, the relation of street surfaces to high water level, and the necessarily wide groove required in the rails, are so great that the deputation cannot recommend its adoption." The people of London are long-suffering, but it is to be feared that even their patience would be exhausted during the period of constructing an underground conduit. In this respect, the inconvenience of constructing a conduit in Berlin has been so great that though the Berlin police authorities will not permit overhead apparatus in the centre of the city, it was some time ago decided not to allow the construction of any more conduit lines on account of the inconvenience arising during construction. It will be seen that the objections to conduits are very real and very serious. They are not insurmountable, but the removal of the difficulties demands a price.

Prof. Kennedy does little more than mention the surface contact and the accumulator, though he foreshadows the possibility of the former system being brought to a practical state. Whatever system of electric tramways is introduced into London, we shall rejoice to see it. We may, however, point out that the L.C.C. is not likely to err on the side of economy.

INDISPENSABLE ACCESSORIES OF ELECTRIC TRACTION.

By HENRY E. P. COTTRELL, A.M.I.C.E.

(*Continued from page* 214.)

Lighting Couplings.

The chief requisites in lighting couplings are simplicity and reliability. Fig. 63 shows a simple and effective form of plug connection for trailer car lighting designed by Messrs. R. W. Blackwell & Co. The holder is fastened below the floor of the balcony ends of the main car, and consists of a socketed brass projection in which the lighting cables end. The trailer lighting cables terminate in a plug of ebonite tapering into a brass holder. To couple up the two the trailer plug is inserted into the socket of the fixed projection

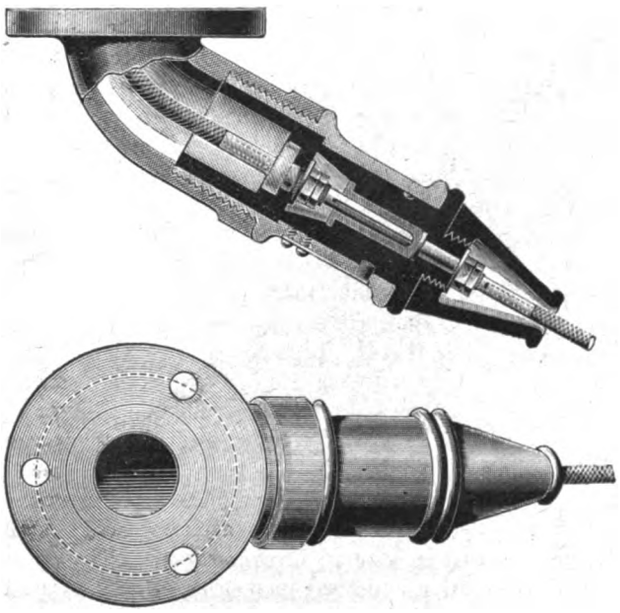

Fig. 63.—Plug Connection for Trailer Car Lighting.

on the main car, the central hollow projection in the socket running into the socket of the plug and receiving the central rod, thus doubly establishing the required connection. This form of coupling is very generally adopted, and fulfils the requisites mentioned above very satisfactorily.

Commutator Segments and Carbon Brushes.

As accessories only are being dealt with in this series of articles, there are only two connected with the motors which will be critically examined; the first are commutator segments, the second commutator brushes. To obtain the standard of thorough efficiency it is most important that commutator segments should be made from metal which is absolutely uniform in texture and fibre throughout, otherwise the flow of the current is interrupted and irregular, heating is generated locally, power is lost, and the segments are more rapidly worn out than they should be. Cast copper even when compressed by stamping is very far from uniform in texture and fibre, and is therefore not satisfactory as a material for commutator segments. These should be forged from drawn rods of wrought copper. The accompanying figs. (64A and 64B) show the operation of breaking down and striking up a forged rod to produce a Westinghouse commutator segment, and figs. 64C and 65 show a T.H.W.P. and an S.C. Westinghouse finished segment, respectively, produced by the drop forging process, which are absolutely free from the imperfections of cast segments, such as porosity, blow-holes, &c. The process consists in forging hot, pickling to remove all oxides, trimming to remove the flash of fin, and finally hitting them a heavy blow when cold, between hardened and accurately gauged dies, to increase the density and impart smooth surface and correct taper and finish.

BILLINGS' PATENT (DROP-FORGED) COMMUTATOR SEGMENTS.

Brushes.

In all motors used on electric cars where the motion has to be reversed in direction, the commutator brushes cannot be constructed of copper, the most satisfactory material in

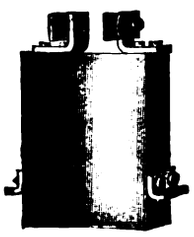

Fig. 66.—Fuse Block.

this case is found to be carbon in certain forms. Carbon in an ordinary way is full of gases and porosities and is therefore wholly unsuitable for the purpose, as it inevitably produces cutting and sparking, both of which materially

Digitized by Google

diminish the life of the commutator as well as the brushes themselves. It is, therefore, essential that the carbon of which the brushes are made should, like the metal of the commutator segments, be uniform in texture and fibre throughout. Furthermore, the brushes should be self-lubricating without being greasy and without clogging or gumming at the tips. The ordinary self-lubricating carbon brush is deficient in all these respects, and although cheap in first cost has a very short and troublesome life and is injurious to the commutator in more ways than one. There is, however, a patent process for producing carbon brushes

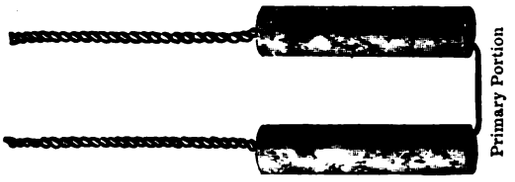

Fig. 67.—Protected Terminal Fuse.

that are free from these drawbacks; by this process the gases contained in the carbon blocks are first extracted, and then the voids are filled by forcing in a special compound, which is a natural lubricant, without being either greasy or oily. This special compound increases the conductivity of the brush and diminishes the specific resistance of the carbon, thus insuring better contact and smaller percentage of loss in the current conveyed, so that the brush is from 7° to 10° cooler than other types of brushes, the life of both commutator and brushes being thus enormously increased. The brushes wear smooth as velvet, and have no tendency to to crumble or break, they require little or no attention, while the commutator is kept constantly lubricated without gumming the segment tips. The compact and uniform texture

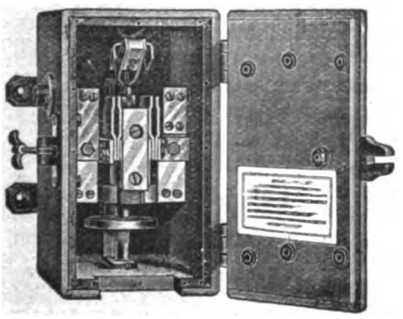

Fig. 68A.—I-T-E Car Circuit Breaker.—Sill Type.

of the surface of these brushes admit of their being plated with either copper or silver, and thus of acquiring the maximum conductivity. The trade name by which they are known is the Le Valley Vitæ Carbon Brush.

Car Circuit Breakers.

The very severe conditions under which the various portions of the equipment of electric tramway cars have to work demand other and more adequate protection than that afforded by fuses. The fuse limits are, in practice, fixed much higher than experience shows is desirable to provide for the jumps in the current which the motors are expected to momentarily sustain. The consequence is, when a short circuit occurs or heavy ground is encountered, the fuse permits dangerously heavy currents to pass without even blowing, and much mischief may ensue unchecked. On the other hand, it often happens that with a heavy load or while ascending a steep gradient, the fuse may blow when it is neither expected nor required to do so; both these drawbacks can be remedied by the substitution of a circuit breaker for an ordinary fuse, and the former to be effective must comply with the following requirements:—

1. They must counteract the careless treatment and abuse of equipment on the part of incompetent or reckless motormen.

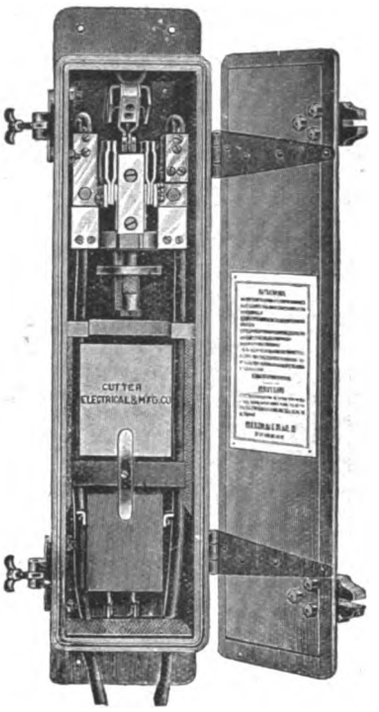

Fig. 68B.—I-T-E Car Circuit Breaker.—Dashboard Type.

2. They must prevent interference with travel and stoppage of service arising from the power station circuit breakers being brought into action through the breaking down of an individual car.

3. They must put a stop to the arcing set up by the sluggishness in blowing of a heavy fuse when ground or short circuit occurs, and the consequent destruction of surrounding material and insulation.

4. They must avoid the development of new faults and flaws in the apparatus during short circuits or ground, contingent on the abnormal carrying capacity of the fuses employed.

5. They must put an end to all burning and blistering of contacts when circuit breakers open.

6. Their adjustment must be independent of friction springs or other fittings liable to alteration, and when adjusted, they must not be able to be altered without the knowledge of the superintendent of equipment.

To ensure the above characteristics, the car circuit breaker must be provided with a fuse block composed of practically indestructible material, connected with a diminutive protected terminal fuse, whose carrying capacity is a small fraction of the lowest adjustment of the instrument. This fuse must be connected in shunt with the circuit breaker contacts so as to blow immediately on the circuit breaker opening, and must be readily replaceable. A record of terminal fuses

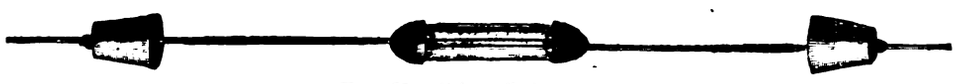

Fig. 69.—"Ajax" Arrester.

expended by each motor man provides a ready check on abuse of equipment, as when a car is properly operated, the necessity for and consequent probability of the contact breaker being opened is reduced to a minimum.

Figs. 66 and 67 show an indestructible fuse block and a convenient form of protected terminal fuse, and figs. 68A and 68B two forms of I.T.E. car circuit breakers, one for fixing on the sill, and the other on the dashboard of a car, which satisfactorily comply with the requirements set forth above.

Digitized by Google

Lightning Arresters.

The destructive passage of currents of very high voltage may also be induced through the connections of a motor car, with all the undesirable consequences detailed above, by the action of lightning, and here the circuit breakers would be inoperative, and a special appliance known as a lightning arrester has to be provided. To be efficient a lightning arrester must be extremely sensitive, and must not be liable

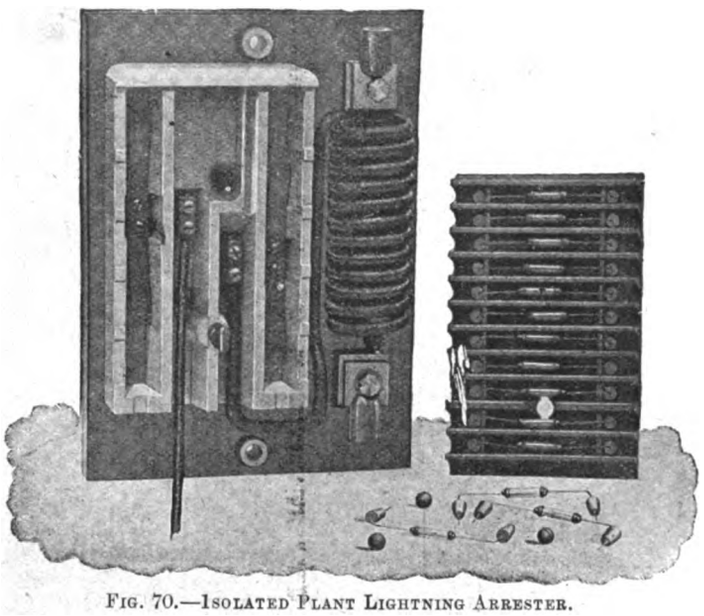

Fig. 70.—Isolated Plant Lightning Arrester.

to getting out of order by contact with dust or damp. Fig. 69 shows a form of fuse (the "Ajax") specially adapted for lightning arrester construction. This consists of two pieces of No. 26 brass wire, each 8 inches in length, having a single silk insulation. These are laid side by side for about 1 inch, as in consecutive armature coils. This lap offers

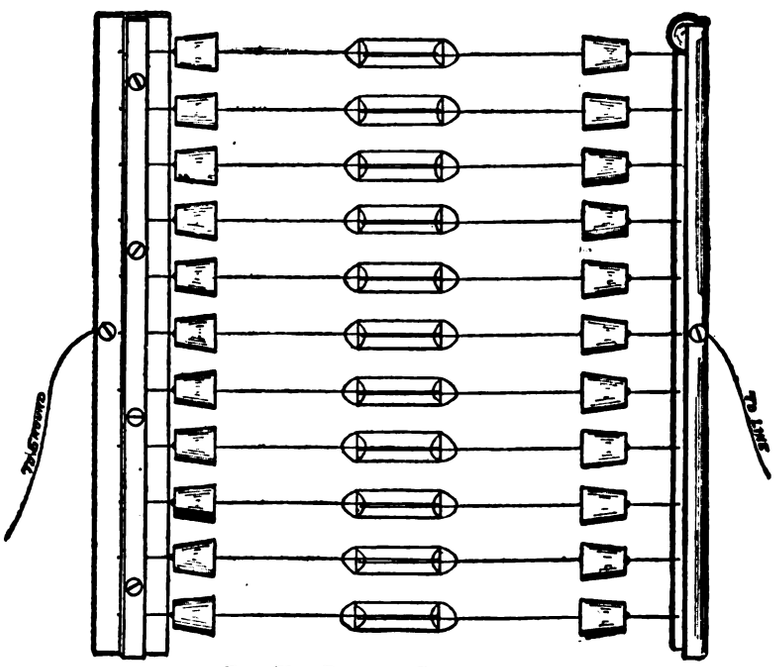

Fig. 71.—Plan of Construction.

abundant surface for the discharge gap which is formed by the two thicknesses of silk amounting to little more than ·002 of an inch. The wires are secured in position by small pellets of highly-insulating wax, and a small glass tube is hermetically sealed over this part of the fuse to keep the dischargers dry and clean till used. Extreme sensitiveness in this part of the fuse is rendered possible by its being called upon to act but once. The ends of the wires are passed through soft rubber plugs, which serve to hold the fuses in the corrugated cover of the arrester (see figs. 69 and 70), and the bare ends projecting through the cover are connected with the line and ground terminals as shown in fig. 71. The fuse frame is fixed on a marble slab, $7\frac{3}{4}$ inches × 11 inches × $\frac{7}{8}$ inch, with an inductance coil in parallel, the latter being connected through the switchboard with the motor and through that to ground.

The adoption of efficient circuit breakers and lightning arresters, such as are above described, reduces the risk of breakdowns due to burned armatures, scorched contacts, and destroyed insulation to infinitesimal proportions, and thus ensures the non-interruption of service so much appreciated by the public.

(*To be continued.*)

THE MACHINE TOOL QUESTION.

In our issue of August 4th we completed a *précis* of an able paper on "Machine Tools," read by Mr. Amos before the Society of Engineers. That the author has bestowed a large share of attention to the subject is clearly shown by the comprehensive and thorough nature of the paper. The machine tool question is assuming dimensions so extended as to render it almost impossible for one mind to possess a detailed grasp of it; much more difficult is it for one firm to do justice to more than a comparatively small section of the industry. The Americans have more fully realised this cardinal truth than the manufacturers on this side, and have as a consequence excelled in their wares, and have thereby provided us food for serious contemplation. Their policy consists of putting into force the well-worn apothegm, "'Tis better to do one thing well than many things badly." This is undoubtedly a great factor in the success of our country cousins. Another factor has been the very high cost of labour prevailing in the States; this has stimulated invention to an enormous extent in reducing hand labour to a minimum and encouraging by convenient arrangements the instant alteration of feed, to deal with changes in the diameter of work. To minimise the time of manipulation the handles controlling the various motions are all brought under the hand of the operator.

An important factor in this tool question, and one which is frequently overlooked, is the miserable want of facilities that English makers have of becoming acquainted with each other's manufactures. A similar difficulty presents itself to the purchasers, whose knowledge of tool makers and types of tools is frequently of the most limited character. This state of affairs is partially due to the jealous manner in which the manufacturers sentinel their workshops against each other, but more largely due, perhaps, to the absence of a journal devoted exclusively to machine tools and manufacture. America has at least two excellent papers of this character, notably *The American Machinist* and *Machinery*. These publications bristle with practical matter by practical men, and it behoves every English manufacturer to include both of them in his literary pabulum.

Added to these elements of advantage must be considered the difference in character of the two nations. We are ponderous and lethargic, while our "cousins" are versatile and energetic. Our brains are probably equal to those of the Americans, but whilst we are considering our ideas the latter go ahead and give effect to theirs. They may make more mistakes, but they "get there" sooner.

The great cry of English makers against the lightness of American tools has now been silenced, with one little exception, which is still adhered to with extraordinary pertinacity. We refer to the tool post, which, in the American design, is a paltry little pillar, with a single screw to secure the tool. The fact of its being so universal in America makes one inclined to think that prejudice has something to do with its disfavour in this country.

Digitized by Google

Whilst fully recognising the impossibility of describing every tool in the market, we feel that there are omissions of one or two tools of sufficient importance to justify our mentioning them without apology to the author of the paper. Among these is a type of large and heavy tools known as "portable tools," which are almost indispensable adjuncts in electrical factories where big units are produced. For the employment of these machines a large cast-iron bed is provided and permanently fixed, the surface being cut up by slots in all directions, and upon this is clamped the work to be dealt with. Various self-contained electrically driven tools, such as slotters, millers, or drillers, are carried about by an electric crane to the required site and put to work; in some cases several tools may be employed simultaneously. Newton, of Philadelphia, among others, makes a specialty of this class of machine.

Another excellent portable tool, chiefly used for engine work, is a planing and slotting machine, by Morton, of Muskegur Heights.

Portable tools may be considered an apt illustration of the mountain coming to Mahomet.

In mentioning automatic screw machines, the Cleveland should not be omitted, it being perhaps the most up-to-date of its class, the time of changing from one size of screw to another being reduced to a minimum by the replacement of the cam plates by a simple screw adjustment.

Mr. Brockie (of arc lamp fame) is now putting on to the market a very wonderful machine of the automatic character and of very simple construction.

In connection with the automatic tools, we are surprised that no reference has been made to the semi-automatic lathe of Gisholt. It is rapidly becoming a necessity in this country for repetition turning and boring work. The exact dimensions are obtained very simply without callipering, by means of adjustable screw stops.

The multiple spindle drilling machine for producing holes not all in a line is a most remunerative labour-saving device. The drills can be set in any position within the capacity of the machine and locked immediately, the motion being conveyed to the spindles by "Hook's" joints.

Reference should be made to the "hogging" machine of Ingersoll, the principal feature of which is the cutter, which consists of a cylinder with a number of circular cutters projecting like the bristles of a "hog." It is not clear whether the name is derived from the position of its cutters or from the fact that it "hogs" off the work.

Talking of cutters brings home the importance of tool grinders generally, and there is absolutely none to hold a candle to that of Sellers, which is the prototype of the Gisholt.

The draw shaper is, perhaps, a type of tool known too well to require description.

In the way of "special tools" the 4-spindle boring machine of Newton's is well worth consideration. By its use the four journals are bored simultaneously by four independent boring heads with 6-inch spindles. This arrangement obviates a boring bar and its contingent spring.

With regard to the question of motor attachments one cannot feel very proud of Muir's drill, which does not give one the impression of being more than an afterthought.

In conclusion, the industry is certainly indebted to Mr. Amos for directing its attention in so able a manner to a subject of so much importance; he strongly recommends that all English engineers before purchasing tools to any extent should cross the "herring pond" and see these wonders for themselves.

SOME NOTES ON THE ELECTRICAL MACHINERY AT THE COMO EXHIBITION.

By KENELM EDGCUMBE, Assoc.M.Inst.C.E.

Although the Como Exhibition has been completely destroyed by the disastrous fire of a few weeks ago, some notes on the more important electrical engineering exhibits which it contained, may perhaps be of interest. With the exception of two or three German firms, all the heavy machinery exhibited was of Italian make, and possessing few features of actual novelty, was, perhaps, chiefly of interest as indicating the present tendency of "Continental" design. For although the conditions obtaining in the various European countries obviously differ enormously from one another, yet there is far greater similarity observable between machines built in Italy and Sweden, for example, than between those produced by two such near neighbours as Great Britain and, say, Belgium.

Whatever may be the cause of this state of affairs—and probably the difference in the ratio of cost of material to cost of labour has much to do with it—any such collection of Continental machines possesses a peculiar interest for British engineers.

In a general way, the most noticeable features are (1) the well-nigh universal use of carbon brushes (and the extremely simple and compact brush-holders used therewith). (2) The almost entire absence of the ordinary upright two-pole horse-shoe magnet. The majority of the smaller machines are of the ironclad type, often with a pair of virtual poles, thus forming a four-pole system. (3) The various devices in use to prevent sparking with slotted armatures. In this connection it may be noted that the Allgemeine Elektricitäts-Gesellschaft appears to be abandoning the Dobrowolski cast-iron pole bushing, except for quite small motors, in favour of the Schuckert skew cut horns. The most usual device, however, and one which has probably been adopted from American practice, is merely to cut down the pole tips so as to concentrate the field by lengthening the air gap under the horns. (4) It may be remarked that in nearly all cases marble is used for switchboards instead of slate. This is partly because the former is inexpensive in Italy, and partly owing to the fact that much of the slate contains veins of metal, and is therefore unreliable for this purpose. It is becoming the almost universal practice to employ an iron frame-work for the panels.

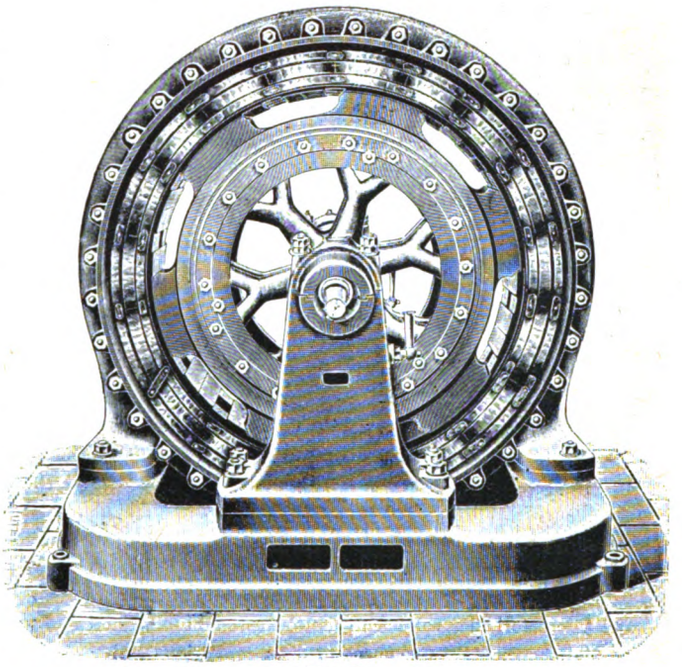

Fig. 1.

Coming now to the actual exhibits. Among those of the Italian firms, perhaps the most interesting display was that of Messrs. Brioschi, Finzi & Co., of Milan. They showed a three-phase inductor alternator of a type which they have constructed for some 12 months with great success, and which presents some interesting features. Fig. 1 shows this machine. The output is 150 kw. at 900 volts. As will be seen from the figure, the field winding is not only fixed, but is wound in slots on the same laminated core as the armature winding. In the particular machine under consideration, the inner and outer sets of coils form the field, while the armature coils, which are of the ordinary type, are "sandwiched" in between them, thus reducing magnetic leakage to a minimum, though of course making efficient insulation more difficult at high voltages. It will be readily seen that as the six laminated poles revolve, the permeance

Digitized by Google

changes in such a way as to cause the field to rotate, and in so doing to cut the armature conductors. These machines, which are said to come out slightly more expensive than those with revolving magnet coils, have the great advantage of enabling the armature and field coils to be replaced with the greatest ease, and without its being necessary to remove the magnets.

Fig. 2 shows in longitudinal section a 200 KW. single-phase alternator with magnetic clutch, built by the same firm. As will be gathered from the figure, the exciting coil

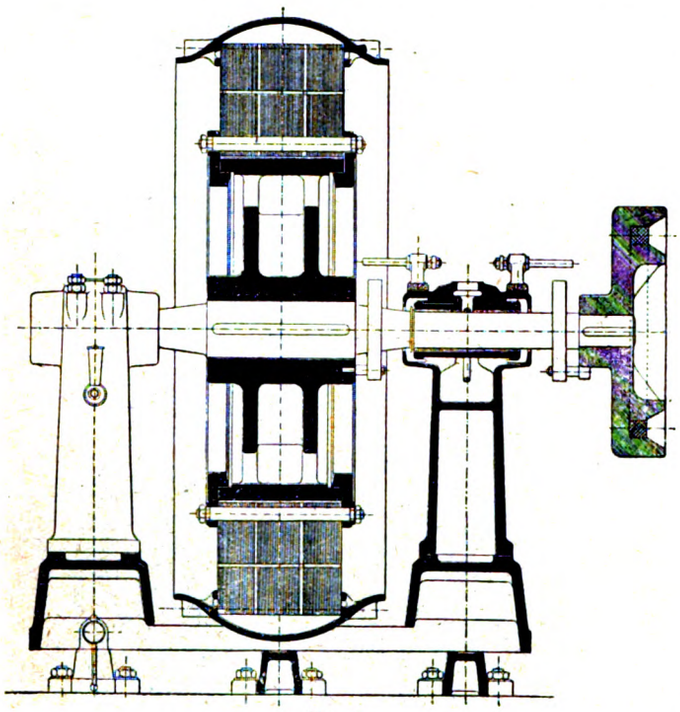

FIG. 2.

of the clutch is in series with the field coils, the current being conveyed to the rotating part by two slip-rings. On test this machine gave the following results:—With a non-inductive load, the full load efficiency was 93 per cent., and the drop in volts, from no load to full load, was 6·5 per cent., the full load voltage being 400. With a load having a power factor of ·8 the efficiency fell to 92 per cent. and the

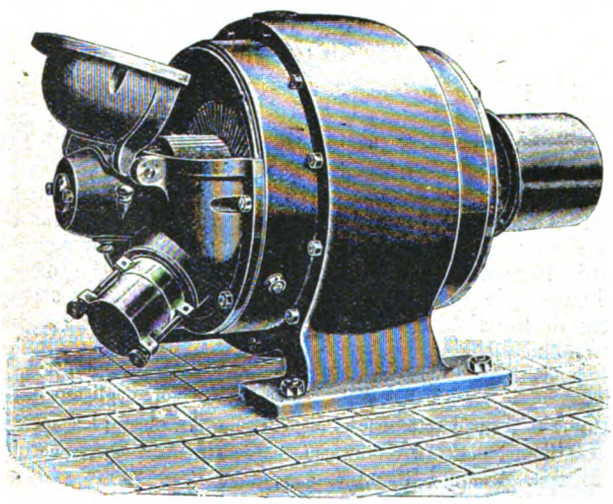

FIG 3.

drop was 25 per cent. The short circuit current proved to be 1,450 amperes, or about three times the normal.

This firm makes a speciality of small motors for driving various classes of machinery, but more especially that used in the silk industry, for which Northern Italy is so famous. For this purpose the motors used are chiefly of the enclosed or semi-enclosed type. Fig. 3 shows a four-pole enclosed continuous current motor of 4 H.P. When the lid is down the motor is hermetically sealed in. The chief peculiarity of this motor is that the entire magnetic circuit consists of laminated iron—not so much to eliminate eddy currents in the poles as to reduce the cross field due to armature reaction. For this purpose the laminations must, of course, be parallel to the armature spindle, thereby offering a greatly increased magnetic resistance to the cross field. The armature, which is slotted, is wound with Eickemeyer coils, held in place by bands. The efficiency of this motor is 85 per cent. at full load. There is also a three-phase 2-H P. motor, arranged for driving a lathe. The speed is reduced to 200 revolutions per minute by gearing fixed to the motor body. This gearing, which consists of a raw-hide pinion driving a cast-iron spur-wheel, has an efficiency of 95 per cent. That of the motor is 79 per cent., so that

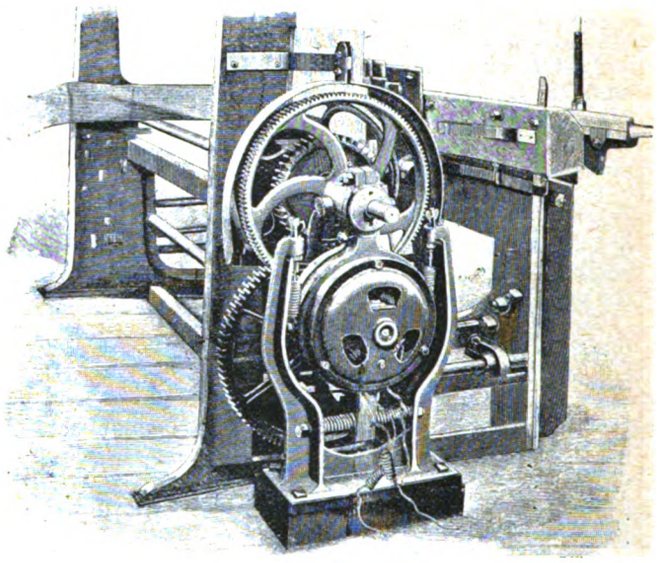

FIG. 4.

the combined efficiency reaches 75 per cent. at full load. The motor is so pivoted that its weight is partially supported by the driving belt, thus securing an even tension on the latter.

In the case of motors driving textile machinery through intermediate gearing, it is usual to support the motor on springs, so as to avoid all shocks. Fig. 4 shows such an arrangement applied to a three-phase motor. The motor body is so suspended as to be capable of swinging about the

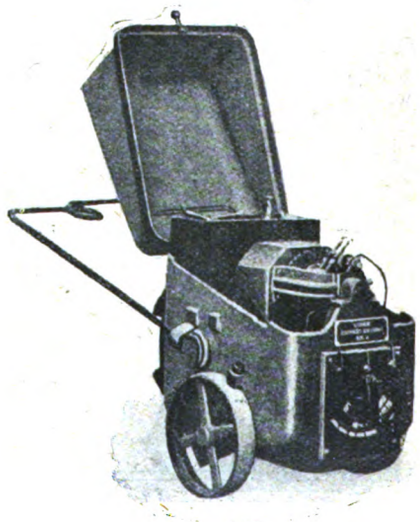

FIG. 5.

axle of the driven machine, its weight being carried by the two vertical spiral springs. In order to keep the motor in position two horizontal springs are applied, one on each side, to an extension of the under side of the case, as will be seen from the figure. By the simple expedient of hanging the motor slightly eccentrically, the distance from centre to centre of driver and driven can be easily adjusted.

The most noticeable feature about the enclosed motors built by this firm is that the outer surface of the case is pro-

Digitized by Google

vided with a series of ribs, which serve the double purpose of strengthening the construction, and of increasing very greatly the cooling surface. In the 1 H.P. motor the surface is nearly 40 per cent. greater than that of the

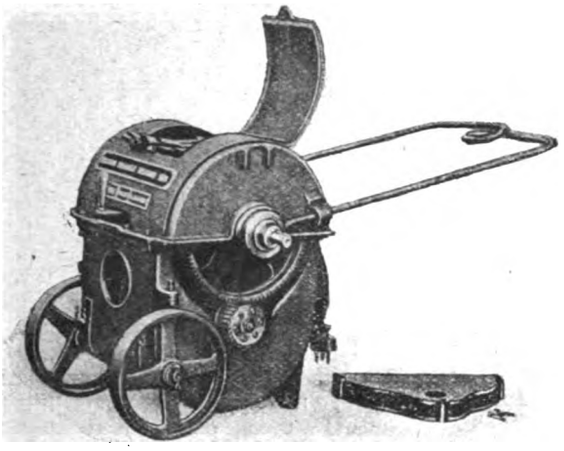

Fig. 6.

corresponding size without ribs. This device is now adopted in nearly all enclosed motors, for with such machines the provision of sufficient radiating surface is always a matter of some difficulty. As an example of the great increase of surface thereby obtained, it may be mentioned that in the case of a 15 H.P. three-phase motor there is a gain of 85 per cent. due to the ribs.

The Allgemeine Elektricitäts-Gesellschaft showed a large number of small machines, of which, perhaps, the most interesting are their portable drilling motors. Fig. 5 shows one of these with the case open. It consists of a continuous current motor of 1 H.P. in a cast-iron box, provided with a

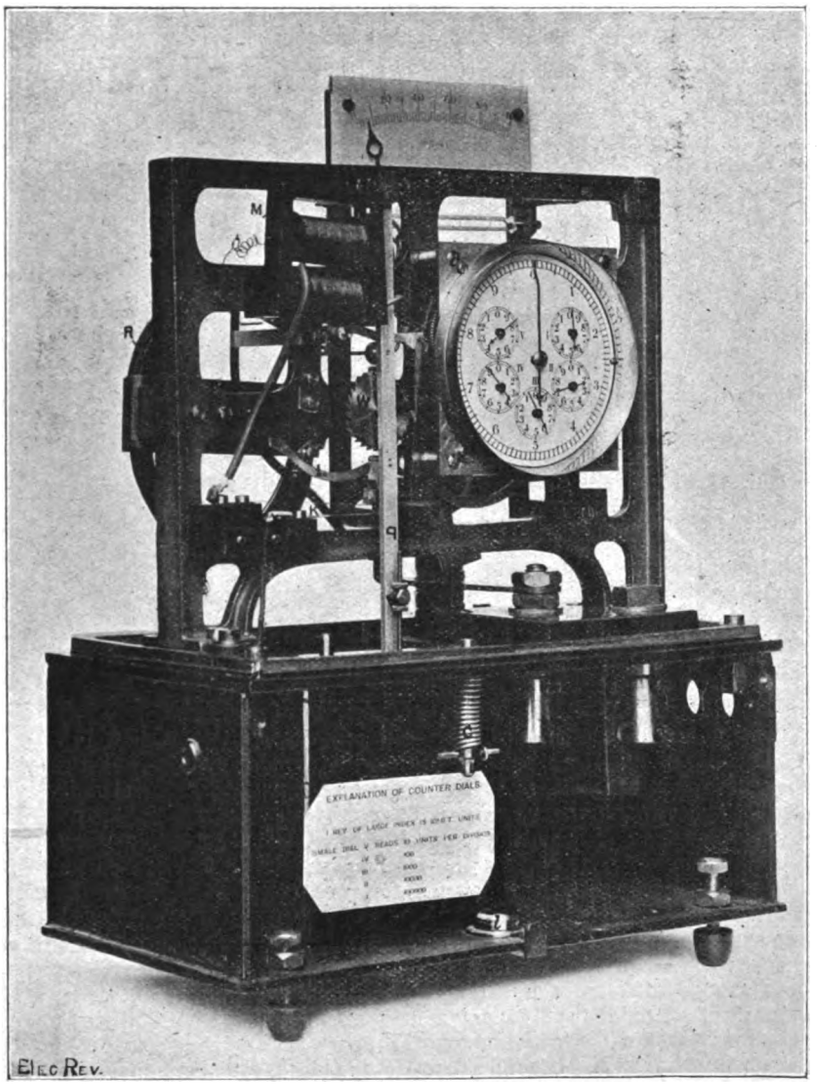
Fig. 7.

movable handle, by means of which the whole can, if required, be slung from a crane, either for transport or to enable the motor to be brought close up to its work, as, for example, in drilling girders in position. The speed is reduced by means of three spur-wheels to 210 or 450 revolutions per minute respectively. By means of a lever either of these speeds can be applied to the drill, or it can be stopped altogether without switching off the current. In the case of three-phase drilling motors, one of which is shown in fig. 6, provision is also made for driving direct off the motor spindle, if required, so that besides the two speeds above mentioned, a speed of 1,440 revolutions per minute can be obtained. The weight of the continuous current 1-H.P. motor is 5 cwt. complete, and that of the corresponding three-phase machine, slightly less. Besides the necessary starting gear, each motor carries a small tool box and several yards of twin cable wound on a drum. As will be seen from the figures, each of the wheels, of which there are but two, can be locked by means of a set-screw, so as to prevent the motor moving, owing to its vibration. Power is transmitted to the drill either by flexible shafting or by a telescopic shaft having a universal joint at each end. The former, which ranges from 5 feet 3 inches to 8 feet 6 inches in length, is constructed to transmit ·2, ·75 and 1·5 H.P. respectively, at 200 revolutions per minute, while the latter transmits 1·5 H.P. at the same speed, and can be extended from 4 feet to 6 feet 7 inches in length. The flexible shafts require supporting in the middle when running. In order to enable several drills (up to four) to be driven by one motor the machine shown in fig. 7 has been devised. The four upper spindles which communicate through flexible shafts with the various drills are driven by the lower spindle, which in its turn is connected by means of either a flexible or telescopic shaft, with the motor. This machine is designed to transmit 1·5 H.P. at 200 revolutions per minute, and weighs about 1 cwt.

(To be continued.)

THE "J. & P." ELECTRICITY SUPPLY METER

This meter, to which we briefly referred in a Note not long ago, we have now had the pleasure of examining. We give below a description of its mechanism, with photographs.



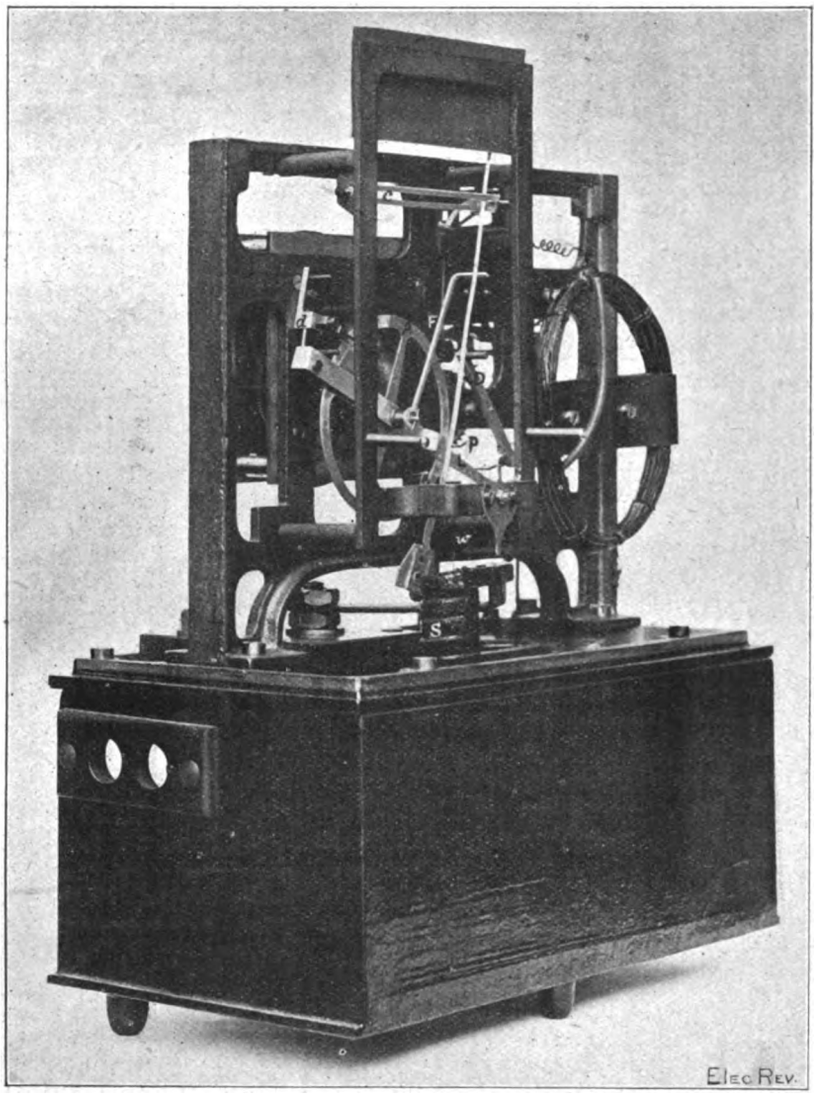
"J. and P." Meter: Front View.

It is a true integrating ammeter for direct or alternating currents, the integration being intermittent—that is, the current is measured at equal intervals of time (usually 30

Digitized by Google

seconds), and a corresponding record is made, which represents the product of the current strength and the time for each such interval. By substituting a wattmeter for the ammeter the instrument becomes an integrating wattmeter, which records the energy supplied to a circuit in Board of Trade units.

In passing, we take this opportunity of protesting against the misuse of the phrase "recording wattmeter." We assert that 99 per cent. of the engineers who use this term have never set eyes on a recording wattmeter, which is an instrument for recording power used at any instant by means of a line traced on a revolving paper cylinder, just as a recording voltmeter registers the pressure which exists at any instant in a similar manner. The proper expression for a meter which records Board of Trade units is *integrating wattmeter*, or *energy-meter*, or *watt-hour meter*; similarly, a meter



"J. and P." Meter: Back View.

which records ampere-hours is an *integrating ammeter*, or *quantity-meter*, or *ampere-hour meter*.

The meter itself presents many novel features. The controlling pendulum, which drives the mechanism, consists of an aluminium rod, P, pivoted at the top, and carrying a leaden bob; the latter swings in a separate chamber, and its beat is regulated by means of the lock nuts seen on the front of the rod. There is a small electro-magnet, M, connected in series with a resistance, R, and a key, K, across the service mains; the pendulum rod carries a loose steel pawl, which trails freely over a block of fibre on the upper side of the key when in full swing, but fails to clear the block, catches in a notch, and depresses the spring contact when the beat falls to a certain minimum extent. The key is thus momentarily closed, and the electro-magnet energised; this happens at intervals depending upon the supply pressure, on the "hit-and-miss" principle, but the effect on the isochronism of the beats is inappreciable, while the average consumption of power is said to be less than 1 watt—a very important feature. The key is always closed when the pendulum is at rest, so that the moment the main circuit is closed the pendulum starts swinging automatically, and by making the key of two springs of unequal length, a rubbing action is obtained, which ensures good contact. The motion of the pendulum is communicated to the mechanism by means of a roller carried on the pendulum rod, which tilts an aluminium lever once in each vibration, and thereby rotates the ratchet wheel, W, through one tooth. The arbor of the ratchet wheel carries a double-ended crank, D, which revolves, with the wheel, once in 30 seconds. The ammeter consists of a solenoid of heavy copper strip, S, in the main circuit, and a fine iron wire, *w*, which is 0·013 inch in diameter and 2 inches long; the latter is suspended in the upper end of the solenoid (which is about 4 inches long) from a pivoted arm, which is controlled by two hair springs, and which also carries the pointer, *p*. The pointer is normally held fast by the clamp, *c*, but during a certain part of each revolution the crank, D, raises a wire which tilts the clamp and sets the pointer, *p*, at liberty to take up a position corresponding with the current strength; during this operation the other end of the crank travels over the curved part of the aluminium lever, L, holding it at rest. The clamp is then applied, and the lever, L, by the continued motion of the crank is allowed to drop slowly, until the feeler, F, rests against the pointer; the end of the lever is provided with a light steel V-shaped pawl, which rests against the edge of the thin aluminium wheel, A, and as the crank comes into contact with the other end of the lever, the pawl engages the rim of the wheel and carries it round through a distance exactly proportional to the displacement of the ammeter pointer. The pawl is a specially noteworthy detail; it will be seen that the combination is exactly similar to that of a pawl and a ratchet wheel with an *infinite number of teeth*, so that there is no backlash or "lost motion." A similar pawl or detent, *d*, is fixed to the frame, and prevents the wheel, A, from being carried backwards by the slight friction of the pawl attached to the lever. The wheel, A, is connected by the usual gearing with a train of dials, the largest of which can be read, in the 10-KW. size, to 0·1 B.T.U. with ease. It is under consideration to replace the dials by numbered drums, as in revolution counters, &c., to further simplify the readings. A novel addition is that of a scale, visible from the outside, by means of which the consumer can tell at a glance what current he is using—if he wants to do so. The scale divisions are perfectly uniform right across the scale. To overcome the slight inaccuracy at very low currents, owing to the iron wire not being saturated, a very clever device is adopted:—One of the controlling hair-springs is firmly attached both to the frame and to the ammeter movement; the other, which is much weaker, is fixed to the latter only, while its outer end is free to rotate with the movement through a small angle before meeting a stop. In this way the controlling force is diminished for currents below the saturation value.

To convert the instrument into an energy-meter, the ammeter is replaced by an ingeniously contrived wattmeter, which, however, is the subject of patents not yet completed, and cannot be here described. The instrument is otherwise unchanged.

The loss in the main coil is very small, not exceeding 8 watts in the 100-ampere size at full load, and frictional errors are entirely absent. The framework and the base are of cast-iron. Levelling screws and a spirit level are provided in the lower chamber, which contains also main terminals of an improved form, and a catch, C, by means of which the

Digitized by Google

pendulum can be clamped for transport and freed when the meter is fixed in place.

The whole of the mechanism is enclosed in a case, which is sealed by the makers. The lower chamber, which contains all requirements for setting up and starting the meter, is provided with a door which can be sealed by the supply undertakers. High insulation is maintained throughout.

The meter, which appears to us to attain a high level of excellence and simplicity, is being manufactured under the supervision of the inventor at Messrs. Johnson & Phillips' works, Old Charlton.

The makers guarantee to keep the meter in good going order, free, for two years, provided that the works are not tampered with, and certify that the error at no part of the range exceeds 1 per cent.

THE REPORT OF THE PACIFIC CABLE COMMITTEE.

(*Continued from page* 224.)

We thus find that after reducing the paying words to four per minute by "a process which interested the Committee very much," and deducting from that limited output still another eight-letter word per minute, to ease the pressure of work, the relays of clerks, although tired of sending these three words per minute, could still continue transmitting the messages for a longer period than 10 hours out of the 24, if such work presented itself! It certainly must be admitted that it is more fatiguing to send three words per minute than, say, 18; and from that point of view it is really a cruelty to the clerk to deprive him of the extra word per minute under the plea of over-pressure, even although he has still the 3½ words of non-paying traffic to relieve him of this strain.

We have gone into this portion of the subject at considerable length, as being probably that which would be of most general interest to readers of the REVIEW, and having examined the various opinions expressed as to the carrying capacity of various cores, and the relative proportions of paying and non-paying traffic, we will now refer briefly to the probable revenue which the Pacific cable might be expected to earn under the conditions which we have detailed. We have shown that on the part of the Eastern Extension Company, who are not unnaturally opposed to the laying of a competing cable, the estimated traffic, as allowed by them, is unduly small, being only 672,000 paying words out of the 1,948,000, which formed the total transmitted in 1895; although, even with this division of the traffic, the Eastern Extension Telegraph Company anticipate a reduction in their receipts of £118,000, should the present rates be maintained (which cannot be expected), or an annual reduction of £197,000 in their revenue, should the rate be reduced to 3s. per word. This estimate appears to be made on the assumption of a non-elastic traffic, and the large increase in the volume of the traffic which experience leads us to expect, consequent upon any considerable reduction in the rate, has, apparently, not entered into this calculation. This is strange, as not long after the Eastern Extension Company reduced the Australian rate from 9s. 4d. per word to 4s. 9d. per word, the traffic increased so rapidly that the total revenue at the reduced rate soon exceeded that of any previous year. The representatives of the Eastern Extension Company, ignoring this experience, anticipate that they would be unable to pay dividends from the Australian traffic, and that "it would be unfair to make the telegraphing public of China, Java, &c., pay higher rates than necessary for the benefit of Australia." And yet, with this sensitive regard for the purse of the public, this company does not seem to realise the unfairness of subjecting the telegraphing public of India to higher rates than they should be charged, so that the Eastern Extension Company, who do not carry messages to Europe, should derive a benefit from the joint purse agreement which they have with the Eastern and other lines which do carry these messages. The Marquis of Tweeddale assumes that, taking a rate of 3s. per word between Australia and England, this amount would be divided up as follows:—2d. to Australia, 4d. for the transit of America, and 1s. for the Atlantic cable which carried the message, leaving 1s. 6d. as the share of the Pacific cable. Mr. J. C. Lamb pointed out that the Government officers in England could do nothing to collect traffic for the Pacific route, except in as far as they would be bound by an old agreement with the Anglo-American Telegraph Company, which was made between the Duke of Montrose, as Postmaster-General, and the Atlantic Telegraph Company and the Anglo-American Telegraph Company in 1868 (31 years ago). This agreement was scheduled to the Telegraph Act, 31 and 32 Vict, c. 110, and the seventh clause is as follows:—"The Postmaster-General to hand to the companies in London all messages which can be sent by the companies' cables, and the companies to hand to the Postmaster-General in London all messages received through the cables, unless otherwise expressly required by the sender in either case." No limit of time is mentioned in this agreement, but it appears that a memorandum was passed between the Postmaster-General and the companies relative to the above Act of Parliament, by which the agreement is limited to 30 years, with clauses providing for a revision of its terms at various specified periods. As the 30 years mentioned in the memorandum have expired, it would be of interest to know what revision has been made, as the Act must have the effect of placing the majority of the Atlantic traffic originating in the United Kingdom at the disposition of the Anglo-American Telegraph Company, who are thus, to a great extent, supported by the English Government against competition.

Mr. Lamb criticises the possible action of the Commercial Cable Company in regard to the collection of traffic for the Pacific route, by saying that it would "give rise to a certain amount of adverse comment that a competitive foreign company was practically acting as agent for a Government line," which presumably means that it would be indelicate on the part of the Commercial Cable Company to attract traffic over their cable, if to reach its destination such traffic had ultimately to pass over the Pacific cable.

Mr. Lamb also said that the Post Office could do nothing towards procuring traffic for the Pacific cable, but does not say by which *viâ*, "Pacific" or "Eastern," the unrouted messages handed in at English telegraph offices would be sent. In virtue, however, of the Act above cited it appears that the English Post Office would be compelled to hand all unrouted traffic for Australia over to the Anglo-American Company, which is, of course, equivalent to routing this traffic *viâ* Pacific. This witness agrees pretty nearly with the Eastern Extension Company's representatives in estimating that one-third of the traffic from Australia would be all that would fall to the share of the Pacific route, and that with a 3s. rate the Pacific cable would retain about 1s. 6d. At this rate Mr. Lamb estimates that for the first year the revenue of the Pacific cable would be £46,500, and that, with a traffic increasing at the rate of 7 per cent. annually, in the tenth year the revenue would be £85,480. In general reference to the laying of the Pacific cable, after referring to the probabilities of cables being laid across the Pacific by foreign Governments, the chairman put the following question to this witness:—

2,395. You would rather see a cable across the Pacific going to Japan and China and to Australia respectively entirely in foreign hands than you would see a British cable in British hands if it was subsidised by the British Government?—Well, I would rather put my answer in this way: that I doubt whether the British Government would be justified in subsidising the cable across the Pacific in order to prevent a foreigner from laying a cable, but of course I would prefer that the whole enterprise, if it is carried out, should be in the hands of the British.

Mr. R. K. Gray pointed out that New South Wales, Victoria, Queensland, and New Zealand being interested in the Pacific cable and controlling the collecting stations, would probably give all their messages to this cable, while in England all the trans-Atlantic cable companies would be anxious to have an increase of traffic, and would therefore become collectors for the Pacific route in Great Britain. The Eastern and the Indo-European Telegraph Companies being the only collectors in Britain for the existing cables have 16 collecting offices in the United Kingdom, while the trans-Atlantic companies have amongst them 58 collecting centres.

Mr. Reeves in his evidence laid stress on the steady growth of telegraph business in New Zealand during years in which

Digitized by Google

this colony was "not specially prosperous." Mr. N. Cork expressed the opinion that the volume of telegraph business with Australia is constantly increasing, his own experience being that between 1891 and 1896 the increase in the number of messages was 63 per cent. The witness also gave an interesting account, showing how the use of the telegraph is gradually but steadily growing in banking business as the rates are decreased. The evidence given by Messrs. T. E. Doxat and C. U. Kingston fully corroborated the opinion expressed by Mr. Cork.

Sir Sandford Fleming, on a basis of a 3s. rate between England and Australia, assumes that the Pacific cable will take 2s. of this amount, and that 50 per cent. of Australian traffic, including the traffic which will arise in Canada, will accrue to the Pacific line. He also pointed out that during the last 20 years the average increase in traffic had been 36·4 per cent., and that in his estimates he had taken less than half of this increase on which to base his calculations.

IPSWICH AS AN ENGINEERING CENTRE.

By E. K. SCOTT.

It is rather surprising that of the London firms who from various reasons have found it advisable to remove their works into the country, none should have hit upon Ipswich. This town seems to be eminently suited for the establishment of engineering works, especially those laying themselves out for colonial and foreign trade. Situated as it is on the Orwell, which is practically an arm of the sea, fairly large steamers can come right up to the Ipswich quays, and in any case it is an easy matter to barge down to Harwich and load direct on to ocean-going boats.

The steady expansion of such well-known firms as Messrs. Ransome, Sims & Jeffries and Messrs. E. R. & F. Turner shows that Ipswich is a good centre for engineering work, and also indicates that suitable workmen and mechanics are to be found in the neighbourhood. With the value of land increasing so rapidly, London will become more and more the city of the middleman, the merchant, and the banker. It is certainly no place for the working mechanic, who likes a bit of ground where he may grow his own vegetables and fruit. As Mr. Orcutt has so eloquently pointed out in the *Engineering Magazine*, the prosperity of an engineering works is intimately bound up with the well being of the workmen, and this is one of the principal reasons why up-to-date engineering establishments in provincial towns go ahead so much more rapidly than old established works and firms which continue to carry on in London.

As with Newcastle-on-Tyne, Ipswich is only served by one railway, but the Great Eastern Company treats the town exceedingly well. The London service consists of over 24 trains each way daily, the time occupied by a single journey being only 1½ hours. Day excursions are run to Manchester for 6s. return as a regular thing, and the boat service from Harwich to Antwerp and the Hook of Holland is one of the most remarkable instances of railway company's enterprise which this country can show.

Messrs. Reavell & Co. have recently set up works in Ipswich for the manufacture of high-speed engines, and Messrs. Maudslay, Sons & Field are moving down there from Westminster Bridge Road. It is also rumoured that a large works for the manufacture of torpedoes is about to be started.

CORRESPONDENCE.

Bankruptcy Proceedings.

In your report of my public examination, you have omitted a very important fact which is sure to do me a great deal of harm in the electrical world. Out of the liabilities which were returned at £4,514, the London and District Bank has a claim of £3,464, which I stated in my examination I knew nothing about. They kept the books, received all takings, and found all monies to carry on the business. How then could I owe them this money when I received from them only my salary?

I took sole control of the business November 24th, 1898, at which time the liabilities to creditors was £1,300. On June 8th, when the petition was presented, the liabilities had been proved to be only about £800. Add to this £150 which I agreed to pay the bank for the £120 they paid the official receiver for the estate of Inrig & Chester, gives us a total of £950. This sum includes £250 claimed for goods on order but not delivered, so that my total indebtedness is only about £700.

At the time the bank took this drastic action I had on my books orders for about £2,000 worth of work, on which about £600 had been spent. The value of my machinery, stock, and plant at invoice prices was £1,864.

I took the business over from the bank with a debt of £1,300, and in seven months I had paid off £600 of this, and could have cleared it all in another four months.

The bank is clearly liable for all these trade debts as there was double the amount when I took control, but had they left me alone I could and would have paid them all.

Alec Gavan Inrig.

Correspondence.—Pressure upon our space compels us to hold over until next week a letter by Mr. Arthur Shippey on "Converting old electric lamps into new," also another communication from a correspondent on the "Renewable lamp."—Eds. Elec. Rev.

THE TELEPHONE BILL.

The Telegraph Act, 1899, is not a very voluminous document, so that we are enabled to print it in full for our readers' information. By this Act, the Government afford facilities for competition in a service in which there should be no competition, and defer indefinitely, if they do not altogether prevent, the acquisition of a complete service by the State. We do not think this Act can be regarded otherwise than as a temporary measure, but we hope, nevertheless, that the popularisation of the telephone, which is desirable—indeed, necessary—may be one of its results.

An Act to make further Provision for the Improvement of Telephonic Communication, and otherwise with respect to Telegraphs.

[August 9th, 1899.]

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. The Treasury may, without prejudice to the exercise of any powers previously given for the like purpose, issue out of the Consolidated Fund or the growing produce thereof such sums not exceeding in the whole the sum of two million pounds, as may be required by the Postmaster-General for the purpose of the Telegraph Acts, 1863 to 1897, according to estimates approved by the Treasury, and sub-sections two and three of section one of the Telegraph Act, 1892 (which relate to the mode in which money may be raised) shall apply with respect to the sum so authorised to be issued.

2.—(1.) Where the council of a borough or an urban district are licensed by the Postmaster-General to provide a system of public telephonic communication, they may defray the expenses of exercising the powers conferred by the license in the case of a borough out of the borough fund or borough rate, and in the case of an urban district not a borough out of the rate out of which the general expenses of the council in the execution of the Public Health Acts are defrayed, and may borrow money for the purpose in accordance with the Public Health Acts, but in the case of a borough any money so borrowed shall be borrowed on the security of the borough fund or borough rate; and the council may, subject to the provisions of the Telegraph Acts, 1863 to 1897, and of the license, exercise their powers under the license throughout the area for which it is granted, although part of that area may be outside the borough or urban district.

(2.) In the application of this Act to Scotland, a Royal or Parliamentary burgh shall be substituted for a borough, and a police burgh for an urban district, and the town council or commissioners thereof, as the case may be, for the council of a borough or urban district, and for the borough fund or borough rate, or rate out of which the general expenses of an urban district council in the execution of the Public Health Acts are defrayed, there shall be substituted the police or the burgh general assessment, or, where there is no assessment so named, an assessment under any head of the burgh assessments or city

Digitized by Google

rate under any local Act payable by occupiers only; and the town council or commissioners, as the case may be, may with the consent of the Secretary for Scotland, borrow for the purposes of this Act on the security of that assessment or rate, but subject to the conditions for the repayment of loans prescribed by the Public Health (Scotland) Act, 1897.

(3) In Ireland expenses incurred for the purpose of this section may be defrayed as expenses incurred in the execution of the Public Health (Ireland) Acts, 1878 to 1896, for sanitary purposes, and money may be borrowed accordingly.

3.—(1.) Where an existing company have before the passing of this Act, under a license from the Postmaster-General, provided a system of public telephonic communication in any exchange area, and it is proposed to grant a new license to a local authority or to another company to provide public telephonic communication in the same exchange area, or any part thereof, then, if the existing company consent to it being made a condition of their license—

(*a*) that they will not give favour or preference to any person whomsoever within the area specified in the new license, and will not, within that area, as a condition of giving a service, require from any person the grant of any facility except for the purpose of supplying telephonic communication to that person; and

(*b*) that their charges shall not, within the area specified in the new license, exceed the maximum rates or fall below the minimum rates authorised in that behalf by the Postmaster-General within that area,

it shall be a condition of the grant of the new license, that where it is proved to the satisfaction of the Postmaster-General that the existing company have incurred or contracted to incur, in the area specified in the new license, material expenditure in laying down underground wires, and have by agreement with any local authority within that area acquired powers for that purpose, those powers shall continue for the period specified in the new license for the duration thereof, but, subject as aforesaid, on the terms and conditions specified in the agreement (including any provisions thereof for determination on breach of covenant), except so far as they may be varied by any subsequent agreement with the local authority.

(2) Where an existing company is at the passing of this Act under a license from the Postmaster-General supplying public telephonic communication in any exchange area, a license to provide a system of public telephonic communication within the same area, or any part thereof, shall not be granted by the Postmaster-General to any person or body other than the council of a borough or urban district, unless it is shown to the satisfaction of the Postmaster-General that the application for the license is approved by the council of each borough or urban district within which it is proposed by the application to establish a telephonic exchange.

(3.) An existing company shall not, without the consent of the Postmaster-General given after the passing of this Act in each case, open an exchange in any exchange area in which they had not, before the passing of this Act, established an effective exchange.

(4.) Where a local authority or a new company, under a license from the Postmaster-General, provides a system of public telephonic communication in the whole or any part of an exchange area in competition with an existing company licensed by the Postmaster-General before the passing of this Act, then, if the existing company consent to it being made a condition of their license:—

(*a*) That they will not give favour or preference to any person whomsoever within the whole of the exchange area in question, and will not, within that exchange area as a condition of giving a service, require from any person the grant of any facility except for the purpose of supplying telephonic communication to that person; and

(*b*) that their charges shall not within the whole of the exchange area in question exceed the maximum rates and (where the company are empowered by agreement with the local authority to lay underground wires) shall not fall below the minimum rates authorised in that behalf by the Postmaster-General within the area specified in the new license,

the license of the existing company shall within the whole of the exchange area in question be extended and continue for the period specified in the new license of the local authority or new company for the duration of such new license, but, except as varied by this Act, the provisions of the license of the existing company (including any provisions thereof for determination on breach of covenant) shall remain in force.

(5.) If the license of an existing company is, under the provisions of this section, extended in respect of any exchange area for a period of not less than eight years beyond the term existing at the passing of this Act, the company shall, at the request of any other licensee of the Postmaster-General providing public telephonic communication in the whole or any part of that exchange area, and under such circumstances and on such terms and conditions as may within six months from the passing of this Act, be prescribed by an order of the Postmaster-General, made with the approval of the Treasury, afford all proper facilities for the transmission of telephonic messages between persons using the system of the company (either in the whole or in part of the exchange area, as the Postmaster-General may prescribe) and persons using the system of such other licensee, provided that the licensee so requiring inter-communication shall in any such case afford similar facilities.

(6.) For the purposes of this section, the expression "exchange area" means an exchange area as defined by any agreement made by an existing company with the Postmaster-General before the passing of this Act.

4. This Act may be cited as the Telegraph Act, 1899, and may be cited with the Telegraph Acts, 1863 to 1897.

American Electrical Apparatus for China.—Our New York namesake says that the Westinghouse Electric and Manufacturing Company, of Pittsburg, with its kindred interests, has been awarded the entire contract for the equipment of the numerous electrical plants which will be installed on the Chinese Eastern Railroad. The contract at present calls for the immediate delivery of three temporary electric lighting plants, each comprising 15 H.P., 20 H.P., and 60 H.P. Westinghouse dynamos. The shipments about to be made are estimated to be worth some $40,000, but, as the apparatus now ordered is only for temporary work, it is assumed that $200,000 will ultimately be involved in the contract.

Arc Lamp Masts.—Messrs. John Spencer, Limited, of Wednesbury, have just completed two electric light masts for the front of the pier and the new square, for the Corporation of Bournemouth. The masts are of wrought steel to designs by Mr. F. W. Lacy, and are 62 feet high by 21 inches diameter, and ½ inch thick.

Bankruptcy Proceedings.—A receiving order has been made in the case of L. Lawrence (Lawrence & Butcher, 5, Stafford Street, Old Bond Street, W.), electrical engineer, on a creditor's petition.

Notice is filed in the *London Gazette* of release of trustee (Mr. H. Brougham) in the case of E. A. Ingold, electrical merchant, Wandsworth Bridge Road.

At Bradford, last week, Arthur B. Blackburn and J. Walker (Blackburn, Walker & Co., electrical and mechanical engineers, Cleckheaton) came up for public examination. The debtors started in Batley Carr in 1893 as electrical engineers, with £10 of their own capital and £30 borrowed. In every year since 1895 they lost money over contracts, and £50 had been lost experimenting. They had not drawn more than an average of 10s. per week. The examination was closed.

At the Liverpool Bankruptcy Court last week, the case of Messrs. Wild, Rothwell & Co., electrical and general engineers, Southport, was up for consideration. An adjournment to October 5th was granted, so that the accounts which had been ordered might be completed.

The first meeting and public examination has been arranged for August 4th and September 19th respectively, in the failure of L. J. Lawrence, electrical engineer, Stafford Street, Old Bond Street, W.

Liquidations, Dissolutions, &c.—The Woking Sanitary Electric Laundry Company meeting at Palace Chambers, Westminster, has resolved to reconstruct. Mr. E. Mann was appointed liquidator to wind up the company. The new company is to be known as the Woking Laundry Company.

The Hiram S. Maxim Electric Lighting and Engineering (Pioneer) Syndicate is winding up voluntarily. Mr H. C. Emery, 15, George Street, Mansion House, E.C., is liquidator.

Messrs. J., J. W., and A. E Palmer (John Palmer & Sons, ironmongers and electricians, of Clifton, Redland and Bristol) have dissolved partnership.

A meeting of New & Mayne, Limited, is to be held at 33, St. Swithin's Lane, E.C., on September 20th, to hear an account of the winding up from the liquidator, Mr. D. F. Basden.

Digitized by Google

Bills which have received the Royal Assent.—The Royal assent has been given to the following Acts:—

Electric Lighting (clauses) Act, 1899.
Telegraph Act, 1899.
Tramways Orders Confirmation (No. 2) Act, 1899.

Catalogues and Lists.—From the "Cotsworth" Arc Lamp and Electric Lighting Syndicate we have received a trade price list of the Cotsworth arc lamps and accessories. Descriptive notes and illustrations are given of the lamps of standard, plain, factory, and inverted types.

Mr. T. M. F. Tamblyn-Watts, of Goldielands, Settle, Yorks, has brought out an electrical catalogue which is intended to serve as a guide in the selection of electrical apparatus for laboratory or for students' use. Various materials have been included in the list, such as wires, bells, telephones, switches, &c., in addition to experimental apparatus, and prices and a few illustrations are given.

Mr. S Schreiber, of Victoria Avenue, Bishopsgate Street Without, sends us a descriptive circular and price list relating to rawhide pinions for noiseless gearing which have been used with good results in the United States and elsewhere for some years past, and also by leading English engineering firms. The rawhide material employed has been made for 25 years past by the Chicago Rawhide Manufacturing Company, Chicago, by a special process. It is claimed to possess great hardness, strength, toughness, general strain resisting qualities, to be impervious to atmospheric changes and to be eminently suitable for electric motor work, motor cars, printing machinery, &c.

We have received from the Cutter Company, Philadelphia, a list of the Q. C. rheostats, in which types B., C., and D. motor starting rheostats, are illustrated, general particulars, code words and prices being also given. The Q. C. field rheostats for different voltages (75 to 500) volts are also included.

Messrs. Polland & Co., of Newcastle-on-Tyne, send us an illustrated circular of the domestic telephone system based on the "P. H. C." micro-telephone, which enables one to use the wiring of any existing electric bell system for telephoning by changing the old pushes for new ones with the metal tubes for pin connectors.

The Edison & Swan Co. has issued a leaflet (No. 130) describing the "Monarch" adjustable ball fitting, which permits the light to be swung from one side of a room to the other without having the flexible cord in any way encumbered, and will sustain any size of enamelled iron or opal glass shade, from 6 inches to 12 inches diameter. The construction is very simple, there being no springs to break, or other mechanism to get out of order, thus rendering it suitable for almost every purpose where a movable light is required. The fitting consists of two balls, the upper ball having a recess on one side of centre in which is a pulley of hard vulcanised fibre. On the opposite side of the centre a hole passes through the ball in a slanting direction from a point in the centre of the upper surface to a point one side of the centre of the lower surface. The lower ball is weighted, and is fitted with a grooved pulley of hard fibre. The flexible cord passes down through the hole in the upper ball, round the pulley in the lower ball, up round the pulley in upper ball and down to the lampholder. The cord not does pass through the lower ball in going to the lampholder, but is left to swing free, thus allowing the light to be carried to any point of angle without being encumbered by the counterweight. The flexible cord between the upper ball and ceiling rose serves as a swivel, allowing one to walk around the room with the light. The fitting is also supplied with a special attachment consisting of a simple revolving shuttle, to which is attached an insulating hook to catch the flexible cord, the shuttle being wound with about 10 feet of line to the free end of which is fastened a five-pointed hook, which permits of its being fastened to a window casing, picture moulding, pigeon-hole of a desk, &c. It is considered well adapted for use in offices, reading rooms, libraries, machine shops, &c.

Charge Dismissed.—The Hon. Charles Rolls and Mr. Ernest Hutton, J.P. were summoned at West London by the police for unlawfully driving motor cars at a speed greater than is reasonable or proper, having regard to the traffic in the highway. Constable Beck said the defendants on the 26th ult. each drove a motor car along Palace Gate, Kensington, and witness estimated the speed they were travelling at as between 14 and 16 miles an hour. Prof. C. V. Boys, F.R.S., said the car ridden by Mr. Rolls was an electrical one, and could not be driven at a high speed. The magistrate was satisfied on the evidence that the constable had been mistaken, and dismissed the summons.

Conditions of Engineer Employment in Germany.—The report for this month of the Amalgamated Society of Engineers, which is abstracted in the *Birmingham Daily Post* for Wednesday, contains some interesting statements by Mr. G. N. Barnes, the secretary, on the conditions of labour in a number of the German engineering works, as shown during a recent "mission" authorised by the society. Workshops were visited in Düsseldorf, Augsburg, Chemnitz, and Berlin. It is stated that "the fencing of machinery, the general protection of workmen, and provision for their comfort are much more complete than in this country, and the shops are more spacious and cleanly. This may be, to some extent, due to stringent Government inspection, brought about contemporaneously with, if not as the result of, accident and other insurance laws; but I am inclined to think that much of it is due to voluntary initiative on the part of employers. Another common feature is the modern appearance of most workshops and the use of first-class appliances. Everywhere new factories are building; machinery is being put down, and a great deal of that at work is dated this year or last. A no less marked feature common to German workshop life is the leisurely manner in which the men go about their work. Although piecework is common, I saw no bustle. With one exception, in all the shops visited men smoked during working hours, and in most of them there were canteens or other provision for getting refreshments while at work." The report states that: "In regard to hours of labour and wages they, of course, compare unfavourably with those current in this country, although there is certainly not the marked difference which is here generally supposed. And when due allowance is made for the stopping time for refreshments, it is doubtful if the actual working time much exceeds that in the area covered in this country by the Employers' Federation. At Düsseldorf the outside or inclusive hours are 60 per week, with one main break in the day—namely, from 12 to 1 30. In Augsburg the hours are the same as at Düsseldorf. But there are two recognised breaks for refreshments in the forenoon and afternoon of a quarter-of-an-hour each, which takes three hours per week from the inclusive time. At Chemnitz the hours are about the same, but vary a little from shop to shop. At Berlin the working day is shorter than elsewhere, but, curiously enough, it varies considerably, in some cases being different in length in different departments of the same firm. The maximum inclusive time is, however, 59 hours per week and the minimum 54. The shortest working day obtains in the largest, best-equipped, most scientifically organised, and best-paying concerns, those of the Allgemeine Electricitäts Gesellschaft, which employ some 14,000 people, and Messrs. Siemens & Halske's, employing nearly as many." Detailed accounts are given as to wages. At Düsseldorf the wages of some 1,200 workpeople averaged over 4s. per day. This included boys and labourers. Most of the fitters and turners were on piecework. There was no sub-contracting, each man being paid through the office, and skilled men earning about 6s. per day as a rule; young men less. The smiths, however, earn more, the earnings of the leading heavy workman averaging 12s. to 13s. per day. The apprentices, who all work together, get 9d. per day for the first year and serve three years. Baths for the workpeople were found at some works, besides refreshment houses and dining-rooms, and on the whole the appointments for the care of those employed would seem to be excellent. Most of the machine tools used were found to be of German make, but there were a few from America and from this country. Altogether the report affords ample evidence of the progressive character of engineering work in Germany.

Crystal Palace School of Practical Engineering.—On Friday last, August 11th, the list of certificates awarded by the examiners in the lecture theatre of the school was presented, Mr. Francis Fox, M.I.C.E., joint engineer of the Great Central Railway, presiding. The report of the examiners showed among other things that in the electrical section the dynamo work of the second term was declared to be particularly satisfactory. Mr. Fox, in his address, referred to a visit he had recently made to America, which showed him that this country is behindhand in engineering, electric light and traction matters. He remarked that men would have to become more highly technical and specialised, or Englishmen would be superseded by Americans in foreign posts and work. Mr. Fox seems to think that there is a great necessity for us to wake up or we shall lose our supremacy, and England may no longer be the workshop of the world.

Electric Launches at Colombo.—Trial trips were successfully made recently with the two new electric launches, the *Water Nymph* and *Venus*. We understand that the electrical apparatus has been made by the Thames Valley Launch Co., Limited, Weybridge, England. The motor is placed at the bottom of the boat—at the stern, while under the seats, which are placed all round the boat, the batteries are put. The electricity is generated by means of a dynamo near the Pettah station, but enough can be stored on the boat to work it for 16 hours, so that a fresh supply will be taken in each day, before starting, the working hours being from six in the morning till nine at night. The power is four-horse, and the boat draws two feet of water. The seats are placed in the larger part of the boat and there is room for 50, for which number the boat is licensed.

For Sale.—The Borough Engineer of St. Helens, Lancashire, is offering for sale a vertical boiler and two Bumstead and Chandler engines, direct coupled to two Castle dynamos. See "Official Notices" this week.

Hull Trucks.—Mr. Maskell E. Curwen, of Victoria Street, S.W., selling agent on this side for the J. G. Brill Company, of Philadelphia, writes as follows:—

We beg to call your attention, which we neglected to do at an earlier date, to your issue of July 21st, page 110. You refer to the truck under the Hull cars as being supplied by the Peckham Company. We desire to call your attention to the fact that all of the trucks so far supplied to Hull are made by the Brill Company, and on page 108 of your above number you show a picture of one of the Hull cars mounted on its truck, said truck showing very plainly that it is a Brill truck. We shall be glad if you will take steps to have this properly corrected at your first possible opportunity.

Finsbury Technical College.—The following is a list of the students who have regularly attended a complete course of instruction for day students (extending over a period of two years for mechanical and electrical engineering students and three years for chemical students) at the Finsbury Technical College, and have now satisfactorily passed the several class examinations:—

Name.	Course.
Bartlett, Arnold W., London C.C. Inter. Scholar	Mechanical Engineering.
Brown, Dugald A., London C.C. Inter. Scholar	Electrical Engineering.
Cazeaux, Sebastian	Mechanical Engineering.
Conradi, Emile S.	Mechanical Engineering.
Cooke, Stanley W.	Mechanical Engineering.
Crush, Hugo P.	Mechanical Engineering.
Endacott, Arthur P., Devon C.C. Scholar	Mechanical Engineering.
Eynon, Lewis	Technical Chemistry.
Fiddian, Kenneth W.	Electrical Engineering.
Fisher, Percy A., London C.C. Inter. Scholar	Electrical Engineering.
Holliday, James W., London C.C. Inter. Scholar	Electrical Engineering.
Howgrave-Graham, Robert P.	Electrical Engineering.
Jeffery, Walter J., Middlesex C.C. Scholar	Mechanical Engineering.
Jollyman, Walter H.	Technical Chemistry.
Jones, Thomas M.	Mechanical Engineering.
Levy, Arthur G.	Technical Chemistry.
Lillywhite, George H.	Mechanical Engineering.
Linford, Walter J., Somerset C.C. Scholar	Electrical Engineering.
Lonnon, William U.	Mechanical Engineering.
Lyddon, Hugh E., London C.C. Inter. Scholar	Mechanical Engineering.
Monk, Reuben G., London C.C. Inter. Scholar	Mechanical Engineering.
Morshead, Leslie R.	Electrical Engineering.
Murphy, Leonard, London C.C. Inter. Scholar	Mechanical Engineering.
Paxton, George S.	Technical Chemistry.
Rolph, William M.	Electrical Engineering.
Seeley Charles G.	Electrical Engineering.

Walsh, Thomas C.	Technical Chemistry.
Wechsler, Elkan	Technical Chemistry.
Woodward, Percy J.	Electrical Engineering.
Yates, Charles F.	Technical Chemistry.
Young, Ernest V.	Electrical Engineering.

Madras Electric Tramways Company, Limited.—On 19th inst. in the Companies Winding-up Court, Mr. Justice Wright, sitting as an additional judge of the Chancery Division of the High Court of Justice, had before him a petition for the compulsory winding-up of the above company, presented by the Electric Construction Company, Limited. We briefly mentioned the case last week.

Mr. Eve, Q.C., said he appeared for creditors for £32,000 odd, and for other creditors for a like amount.

Mr. Herbert Reed, Q.C., who appeared for the Madras Company, asked his Lordship not to make the order applied for, as no useful purpose would be served by winding up the company, on all the property of which the applicants held a first mortgage; they had debentures covering everything, and there was nothing else whatever. They had been in that position for a long time. His (counsel's) affidavit showed that the company was formed to construct tramways in Madras, the period of construction occupying a long time, and there had been considerable delay, but it was believed that if they were got into working order and a reasonable time allowed them, there would be enough to pay all the debenture holders. It was also proposed to have another form of electrical construction, and recently the petitioners were offered £65,000 to pay them off, their (the petitioning creditors') debt being £72,000 on their own statement, allowing for all the interest which was due to them; and they being the mortgagees in possession. His Lordship would see that the margin was exceedingly small, and if petitioners had been willing to take the £65,000 they would have been paid off. The affidavit also stated that a strong committee was now being formed in Madras. The position of affairs was very serious, as the shareholders were in many instances natives of Madras and people in poor circumstances, who had invested all they had in the company, and the whole of whose interest would be destroyed through winding-up. Trustees of the debenture holders had been appointed in Madras, and they hoped to be in a position to work the tramways. All the troubles of the company had been caused by the petitioning creditorr. Great damage was caused by delay, and the company was obliged to submit to have work done by those creditors, which gave the latter the right under which they now petitioned. The directors strongly believed in the future of the company, and as a proof of that he (Mr. Reed) might say that for five years they had given up their fees, and the chairman had also given up his fees, which alone amounted to £650 a year.

Mr. Eve, in reply, said that in March, 1898, an agreement was come to between the company and the British Electrical Company with a view to seeing whether the latter would take it over and get rid of the creditors. They gave them from March, 1898, to June this year to make some arrangement of that kind, and they had held their hands for 15 months. In order to raise a sum of £8,000 a second series of debentures was issued, and out of that £3,000 was paid to the British Electrical Company. What they complained of was that an office was being kept open in Madras, for which the petitioners had to find the money. There was not a penny coming in for the shareholders to enable that office to be kept open, and it was only piling on liabilities, which would go on increasing, if they allowed the matter to stand over. That would be to the prejudice of the petitioners.

After some further argument, his Lordship ordered the case to stand over until the first petition day in November. If by that time nothing had been done the order for winding-up would be made.

Phillips' Monthly Register.—Mr. C. D. Phillips (*Phillips' Machinery Register*), of Newport, Mon., announces that he has just opened an electrical department. He has decided to publish a supplement of new and second-hand electrical plant for purchase and sale along with his monthly register.

Plymouth Electric Tramways.—In our article on Plymouth electric light and tram undertaking last week, we omitted to say that the Peckham trucks, and all overhead line material were supplied and successfully erected by Messrs. R. W. Blackwell & Co., of London, who were sub-contractors to Messrs. The Westinghouse Electric Company of London.

Phosphor Bronze Company.—A petition presented to the High Court of Justice for confirming a resolution reducing the capital of the Phosphor Bronze Company from £90 000 to £45,000, will be heard by Mr. Justice Kekewich, on October 28th.

Suicide.—On Saturday last, A. R. Marshall, formerly employed by the National Free Wiring Company, of Egremont, committed suicide at Seacombe, by shooting himself. A warrant had been issued on the previous day for his arrest on a charge of embezzling money belonging to the company.

The Castner-Kellner Litigation.—A financial paper understands that the Castner-Kellner Co.'s recent application to the House of Lords desiring that the Commercial Development Corporation, Limited, should, in the event of the former succeeding in their appeal to the House of Lords, give an undertaking to repay any costs they have been ordered by the Court of Appeal now to pay, failed, as a similar application to the Court of Appeal had previously failed.

Theft.—At Southwark, on Monday, George Smith, 37, was sentenced to six months' hard labour for stealing a coil of electric wire, value £6, from Mr. V. G. Middleton, electrician, who had been carrying out some work at Messrs. Clowes, printers, Duke Street. As considerable quantities of wire had been missed, a galvanometer was made to play the part of a thief detector. Two wires connected the coil with the warehouse so that immediately the coil was touched the needle of the galvancmeter would move and thus indicate what was taking place. Prisoner was caught handing the wire over to a woman.

The Glasgow 1901 Exhibition.—We read in the *Engineer* that the Machinery and Electric Lighting Committee of the Glasgow International Exhibition, 1901, have agreed to accept as exhibits for producing steam for electric lighting and motive power, the following:—Lancashire boilers from Messrs. Penman & Co., Glasgow; water-tube boilers from Messrs. Babcock & Wilcox, Limited, Glasgow; Messrs. Stirling & Co., Limited, Edinburgh; Messrs. Weir, Limited, Cathcart, Glasgow; Mr. W. E. Berry, Manchester; and Messrs. Penman & Co., Glasgow. It is estimated that the total power required will be about 5,000 H.P.

Trade Announcements.—The Imperial Electrical Engineering and Stamping Company have taken over the business of Harrison & Co., 133, High Street, Aston, and will devote themselves to the manufacture of special types of switches at their newly-fitted works, 63, Lionel Street, Birmingham.

Messrs. H. M. Salmony & Co., Limited, of Charing Cross Road, having disposed of their accessories and fittings department, announce that they have considerably increased their engineering department, and are prepared to undertake the erection of complete lighting and power plants. They will also trade in the Upton Midget enclosed arc lamps, dynamos and motors, Hart switches, Stirling railway supplies, ironclad rheostats and measuring instruments. The Sun Electrical Company, formerly trading as the Salmony Electrical Company, has purchased the fittings and accessories business referred to.

We are asked to state that the trade announcement sent to us by the Jandus Company, and published in the ELECTRICAL REVIEW for July 28th, requesting that communications should be addressed to the Hartham Road works, related only to the supply of manufacturing requirements to the company. All communications relating to the sale or working of the Jandus lamps, as also all matters relating to licenses to manufacture under royalty, should be addressed as hitherto to the company's sole agents, Messrs. Drake & Gorham, 66, Victoria Street, Westminster, S.W.

Messrs. Frederick Bamford and H. Duckworth Halstead inform us that they have entered into partnership as Bamford & Halstead, consulting, mechanical and electrical engineers, at 49, Deansgate, Manchester.

The Phœnix Dynamo Company has removed from Hubert Street, Leeds Road, Bradford, to Joseph Street Works, Bradford. The new works, which are three times larger than the old place, are more centrally situated and better adapted to the company's purposes.

Trolley Poles.—We have before us a circular of the steel trolley poles for electric car equipment as supplied by the Pittsburg Trolley Pole Company, of Pittsburg, Pa. This company manufacture poles from steel pipe of a superior quality, made especially for their purposes. They have had new machinery erected at the works recently, by which they are able under a special process to produce at one heating of the steel pipe a trolley pole complete, before leaving the machine, of uniform taper, smoothness and strength. The process is covered by letters patent, and the Pittsburg Company has the exclusive right of manufacture.

ELECTRIC LIGHTING NOTES.

Bolton.—A dispute has occurred between the Corporation and the electrical fitters in their employ. The men refused to work overtime except at special rates, and apprentices were told off to do an emergency job, but declined, and subsequently the whole of the

Digitized by Google

workmen took their tools out. As several important works are in progress, men have been introduced from other towns, principally Liverpool.

Bradford.—Mr. W. A. Ducat, Local Government Board inspector, held an inquiry last week into an application by the Town Council for sanction to borrow £37,500 for extensions of the electricity works and mains.

Brechin.—The Police Commission has agreed to transfer its provisional order to the Angus Electric Light and Power Company, Limited, Messrs. Edmundson, Limited, being guarantors, and to appoint Mr. Lackie, Glasgow, to see to the proper carrying out of the work on behalf of the town.

Bury St. Edmunds.—The Town Council is applying for sanction to a loan of £600 for lighting certain roads with electricity.

Calcutta.—We are informed by the Calcutta Electric Supply Corporation, Limited, that Mr. B. N. Sen is not chief engineer, but engineer-in-charge of the electricity works, under Mr. K. A. Scott-Moncrieff, who has been chief engineer of the company in Calcutta from the commencement.

Camberley.—The District Council is considering the advisability of applying for a provisional order, and has decided to obtain a report on the subject from an expert.

Cardiff.—The Town Council has increased the salary of Mr. Appelbee, the electrical engineer, from £300 to £350.

Cleethorpes.—The District Council is endeavouring to arrange with the Grimsby Tramway Company for a joint electricity works to supply both lighting and traction.

Cork.—The City Council has caused a large number of arc lamps of different types to be erected in the principal streets, in order to decide which kind should be adopted for the public lighting.

Dartmouth.—The Town Council has agreed to offer no opposition to the Urban Electric Lighting Supply Company in obtaining a provisional order. The Council will have the option of purchase at the end of 14 years, or any subsequent period of five years.

Devonport.—The Corporation has obtained a satisfactory site for the electricity works in East Stonehouse, and has come to an agreement with the Urban Council of that district to treat the borough and the district as one area for electric lighting purposes. The District Council agrees to oppose any application for lighting powers, save that of the Devonport authorities, so long as the latter carry out their obligations; Plymouth is therefore barred from Stonehouse, which lies midway between the two.

Dolgelly.—The question of lighting the town by electricity is under the consideration of the District Council.

Frinley.—The District Council has resolved to employ an expert to report on a scheme for lighting the district with electricity.

Glasgow.—The annual report and balance-sheet of the electricity undertaking for the year ended May 31st, 1899, shows that the gross revenue amounts to £44,141 4s. 7d., and the gross (or working) expenditure to £24,013 4s. 3d., to which is added depreciation written off capital, £7,520 18s., making together £31,534 2s. 3d., the balance carried to profit and loss account being £12,607 2s. 4d., out of which the Committee had to meet the following requirements:—(1) Interest on loans, £7,445 17s. 3d.; (2) sinking fund, £3,220—£10,665 17s. 3d.; leaving a balance of £1,941 5s. 1d., which has been placed to credit of reserve fund account. With reference to the prices to be charged for energy supplied, either for lighting or for motive power purposes during the year which commenced on June 1st last, the Committee recommend that the same should remain as they were last year, except that to all consumers supplied at 250 volts the second or rebate rate be 1½d. per unit instead of 2d. as heretofore. The quantity of electricity sold to private consumers during the past year was 2,566,016 units, as compared with 1,885,902 units during the previous year, being an increase of 36·06 per cent. The number of private consumers on May 31st, 1899, was 1,858, as compared with 1,437 at May 31st, 1898, being an increase of 421 or 29·29 per cent. during the year. There were 52 consumers who consumed the equivalent of five hours or over per day of their maximum demand throughout the year. The number of motors in use and supplied off the Corporation mains at May 31st, 1899, was 78. The total number of arc lamps erected and in regular use in the streets as at May 31st, 1899, was 227, as compared with 119 at the same date last year; and the quantity of electricity consumed for street lighting was 258,334 units, as compared with 228,134 during the preceding year. This increase would have been much greater but for the fact that the lighting of the Springburn route only came into operation in February last. The number of 8 C.P. lamps applied for, or the equivalent in other devices, as recorded on May 31st, 1899, was 191,062, as compared with 150,000 in the corresponding date in the preceding year, being an increase of 27·37 per cent. The number of units consumed, per lamp fixed, by private consumers, averaged out month by month according to date of connecting up, was 14·8, as compared with 15·17 during the previous year, the falling off being due to the curtailment of supply during last winter. The maximum load or demand made upon the generating stations during the year occurred on December 22nd, 1898, and was 3,095·9 kilowatts, which was beyond the capacity of the plant available last winter.

Glossop.—The Town Council is negotiating with private companies with a view to selling its electric lighting order.

Gosport.—The Electrical Power Distribution Company has notified the District Council of its intention to apply for a provisional order; the Council, however, has resolved to apply on its own account.

Halifax.—The Town Council has decided upon an extension of the electricity works, practically doubling the present accommodation. When completed, the new building will afford capacity for machinery of the total value of over £60,000. The extension is to be commenced at once, as the tramway developments and the increasing demand for the electric light permit of no delay.

Harrogate.—The Council decided on August 14th to extend the electric lighting station and the mains, and to purchase new plant, at a cost of £28,000. Application will be made to the Local Government Board for sanction to a loan of that amount.

Hertford.—The Corporation has resolved to dispose of its provisional order to the Municipal Electric Supply Company.

Kesteven County Asylum.—The Local Government Board has held an inquiry into the application of the Kesteven County Council for sanction to a loan of £14,000 for the erection of a new asylum near Sleaford, including £5,000 for electric lighting.

Lowestoft.—The Local Government Board has sanctioned the borrowing by the Council of £30,000 for electric lighting.

Lytham.—The District Council has accepted Mr. Tiddeman's scheme for electric lighting, as amended by Mr. Tonge, and has instructed him to prepare the necessary plans and specifications, and to invite tenders for carrying out the work. The Council has also decided to make application to the Local Government Board for the necessary borrowing powers.

Maidstone.—The District Council has decided upon the erection of a dust destructor at an estimated cost of £4,270, to be worked in conjunction with the electric lighting scheme.

Marylebone.—Messrs. Whamond, Williams & Co., accountants, have valued for the Marylebone Vestry the Marylebone electricity plant of the Metropolitan Electric Supply Company, which the Vestry is desirous of acquiring. They allow £319,735 in respect of capital expenditure, £305,283 for goodwill and other items, making a total of £643,580. On the other hand, Messrs. Deloitte, Dever, Griffiths & Co., the accountants to the company, agreeing as to £319,735 representing capital expenditure on the Marylebone section, estimate the goodwill value of the undertaking at £613,476, their total estimate thus being £933,211, hence a difference of £289,631. The Vestry will consider the report after the vacation.

Penarth.—The District Council is negotiating with the Electrical Power Distribution Company respecting the electric lighting order. The company desires an extension of the time for compulsory purchase.

Penzance.—The Town Council is considering the question of applying for a provisional order for electric lighting.

Perth (W.A.).—Electric train lighting has been introduced for the first time in the colony, on the goldfields railway.

Rhyl.—The Urban District Council on Monday passed the Electric Lighting Committee's recommendation that Messrs. Trentham & Peers prepare a scheme, report, and plans for an electric lighting installation and refuse destructor.

Scarborough.—A Corporation Committee has been appointed to consider and report upon the question of acquiring the undertaking of the Scarborough Electric Supply Company, Limited.

Stirling.—It is expected that the electricity supply will be available for the coming winter. The scale of charges will be:—For lighting, for the first 500 units per annum, 6d. per unit; for the next 500 units, 5½d.; for the next 1,000 units, 5d.; for the third 1,000, 4½d.; and for every additional unit above 3,000, 4¼d. per unit. For motive power, not exceeding 50,000 units per annum, 3d. per unit; exceeding 50,000, on terms to be arranged.

Sudbury.—The town is suffering under a gas supply at 4s. 6d. per 1,000 feet, and the Town Council is considering the question of electric lighting. As a new sewerage scheme is in hand, the engineer, Mr. Eayres, suggested that the pumps for the latter should be driven electrically, so as to dispense with a separate power station. Mr. Eayres's suggestion, we would point out, is of very great importance to the success of this and similar undertakings. It is possible to so design the pumping installation that the latter may be shut down during the hours of heavy lighting load and regulated at other times, so as to maintain a practically constant load on the generating plant. Under these conditions electricity could be supplied at a profit for 1d. or 2d. per unit.

Sydney.—The City Council is taking steps towards lighting the city with electricity, and has communicated with the Agent-General with a view to obtaining the services of an expert technical adviser.

Wimbledon.—The District Council has received a report from Mr. Preece to the effect that the original estimate of £37,000 for electric lighting had already been exceeded by £10,000, and that a further sum of £10,000 was required for immediate extensions, the plant being fully loaded.

Yarmouth.—The income for the past quarter was £1,209 15s., sufficient to pay all works' costs and capital charges, and to leave a small profit. The Council is making inquiries as to the cost of an additional 150 K.W. alternating set.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Blackrock.—A collision occurred on the 13th inst., between an electric car and a hackney car; the latter was upset, and one of the three occupants was seriously injured.

Bradford.—On August 14th a little girl, four years old, was knocked down by an electric tramcar. The child was caught on the guard, and received slight injuries.

Cheltenham.—The Town Council has approved of a new route for the tramways through the town, joining the section already sanctioned to Cleeve Hill.

Dover.—The municipal electric trams are doing excellently. The season has been very satisfactory so far as they are concerned, a record of 20,000 passengers in one day having been made.

Germany.—Messrs. Siemens & Halske, of Berlin, are preparing plans for a projected electric railway in the town of Coburg.

Glasgow.—The Tramways Committee on August 15th, on Mr. Parshall's recommendation, accepted the tender of Messrs. E. P. Allis & Co., U.S.A., for steam engines, the price being £114,554.

Ilford.—A committee, which visited Glasgow and other places, has reported to the District Council in favour of the trolley system. Mr. Hawtayne is to be asked to prepare an estimate for the construction of the tramways.

Ipswich.—The Town Council has had under consideration the question of purchasing the tramways from the Ipswich Tramways Company, at a price to be decided by arbitration. Mr. J. E. Waller, of Messrs. Kincaid, Waller & Manville, has prepared a report for the Parliamentary Committee, in which he states that the lines would require entire reconstruction for electrical working, and recommends extensions amounting to about 4½ miles. The total outlay Mr. Waller estimates at £83,000, exclusive of generating plant and feeders, which would be provided by the Electric Lighting Committee, and he recommends the combination of the lighting and traction works in one station. The Council will take immediate action in the matter.

Leamington.—The Leamington and Warwick Tramways Company is desirous of introducing electric traction, and will probably obtain assistance from the British Electric Traction Company.

Leeds.—The Corporation is about to invite tenders for 50 additional electric cars.

Liverpool.—The City Council has resolved to apply to the Local Government Board for sanction to a loan of £300,000 for electrical purposes.

A serious accident occurred on August 13th, at 9.30 p.m.; a bus which was turning the corner of Crown Street into Upper Parliament Street was run into and overturned by an electric tram proceeding in the direction of Smithdown Road. The collision, which occurred without warning, caused great consternation among the passengers, who were scattered in all directions, and several of them sustained serious injuries.

London.—In a communication to the *Daily Graphic* last week, Mr. Holroyd Smith suggests that while the County Council is laying conduits for the electric tramways south of the Thames, it may as well go further, and construct a large subway under the track to accommodate the various gas, water, and electric mains. For this purpose, he would place the slots in the two rails nearest the centre of the roadway instead of in the middle of each track as is usual, so as to bring them over the subway. The idea is attractive, but would involve an immense expenditure, and we do not expect that it will go any further.

Plymouth.—Sanction has been received by the Plymouth Corporation to their proposal to borrow £18,000 for the reconstruction of the Compton section of their tramways and the equipment of them for electrical traction. The Tramways Committee have decided to invite tenders for the supply of rails and bonds with a view to the early commencement of the work, which, however, will not be completed until a scheme for widening part of the roadway, which is now in progress, has been carried out. A further extension of the eastern section of electrical tramways is to form the subject of an application for a provisional order next session.

Portsmouth.—On the 10th inst. Mr. F. J. S. Hopwood, C.B., from the Board of Trade, sat at Portsmouth to hear an objection of the Portsmouth Corporation in respect to a light electric railway from Cosham to Horndean, to cross Portsdown Hill. It was stated that the War Department was in favour of its construction for military purposes, there being forts on the hill, where it is intended hereafter to erect a military hospital. The scheme was passed by the Light Railway Commissioners, after an inquiry which was presided over by the Earl of Jersey. The Portsmouth Corporation has obtained powers to take over the Portsmouth tramways, and it objected to the terminus of the light railway being made at a narrow part of the road leading out of Portsmouth, on the ground that it would be dangerous to passengers, as there was a good deal of road traffic there. After hearing statements on either side Mr. Hopwood suggested that the parties might agree upon a temporary arrangement, with a view of making a junction between the tramways and the light railway. The War Office and another public department were anxious to see the light railway constructed at an early date, as it would be useful for military purposes. He should advise the Board of Trade on the matter and communicate the result to the parties, who he thought might easily arrange their differences.

Sunderland.—The Corporation Tramways Bill has received the Royal assent, and the Council has agreed to purchase the undertaking from the Sunderland Tramways Company at a cost of £35,000. The whole of the old and new routes are to be electrically equipped by August 31st, 1900, the total expenditure being estimated at £126,618. The estimate of the electrical engineer, Mr. Snell, was £120,600—a very good approximation. The contract has been placed in the hands of Messrs. Dick, Kerr & Co.

The New York Elevated.—According to the *American Electrician*, the Manhattan Railway Company, in July, decided to place a contract with the E. P. Allis Company, Milwaukee, for 8 8,000-H.P. engines, capable on overloads of developing 100,000 H.P. The company had already selected a location for a power house and placed a heavy order for third rails. These engines will be by far the largest ever used for driving electrical generators, having just double the capacity of the 11 4,000-H.P. sets now under erection for the Metropolitan Street Railway Company, New York City. The power station of the elevated will have exactly the same capacity as that planned for the Third Avenue Railroad of New York City, for which 16 4,000-H.P. units were proposed.

Westbury.—The Bristol Tramways Company, Limited, in response to a petition from residents, has promised to obtain powers for extensions to Westbury at the next opportunity.

York.—The Tramways Company applied to the City Council some time ago for leave to adopt electric traction; the Council has now decided to open negotiations with the company with a view to purchase.

TELEGRAPH AND TELEPHONE NOTES.

African Trans-Continental Telegraphs.—The report of the Commissioners of the British Central Africa Protectorate for the year ended March 31st, of which a lengthy summary appears in the *Times* for Tuesday last says with regard to the Trans-African telegraph:—

> The African Trans-Continental Telegraph Company have proceeded steadily with the construction of their line to the north, which is now completed to a point close to the south end of Lake Tanganyika. By the time this report reaches England the line will have been formally opened up to Tanganyika. A branch line is now in course of construction from Domira Bay, on the west shore of Lake Nyasa, to Fort Jameson, the headquarters of the British South Africa Chartered Company in Mpeseni's country. With regard to the extension northward of the African Trans-Continental Telegraph Company's line from the south end of Lake Tanganyika towards Uganda, I am informed by the company's representative that a steamer of considerable size has already been ordered in England for Lake Tanganyika, to be used both for the transport of telegraph material from the south end of that lake to various points on its eastern shore, and also for telegraph purposes after the construction of the line is completed. The telegraph company have now a large number of native operators, and they find that the educated African, as turned out by the various missions in the country, takes readily to telegraph work. Dr. Laws, the head of the Free Church of Scotland Mission in the Nyasa districts, has established a short line of telegraph at the Kondowe Mission, and has a special class of natives who are trained for this work. By thus using native telegraph operators it will probably be possible in future to carry on the work of the African Trans-Continental Telegraph Company's lines with only a very moderate number of European employés. From April 1st, 1898, to March 31st, 1899, 176½ miles of line were constructed and strained—*i.e.*, from Kota Kota to 44 miles beyond Karonga. Blantyre is now in direct communication with London *viâ* Cape Town on the one hand, and with the most northerly part of Lake Nyasa on the other. A Belgian expedition, under the command of Mr. Mohun, passed through the protectorate in the commencement of 1899 for Tanganyika, its object being to erect a telegraph line from a point on the west shore of Lake Tanganyika to the Congo river. A German expedition also passed through with material, &c., to place a new steamer on Lake Tanganyika.

Bradford Telephones.—The Bradford Corporation last week held a special meeting to consider the question of giving notice to the National Telephone Company to determine the agreement as to wayleaves between the Corporation and the company, dated August 20th, 1896. A resolution to that effect was passed, and the town clerk was instructed to carry out the necessary steps.

Congratulations.—We are glad to observe that Don Primitivo Vigil y Lopez Losada, who has on several occasions represented Spanish Government interests during the laying of submarine cables by English companies, has recently been promoted to the position of "Director de Seccion" of the first class.

Glasgow Telephones.—The Corporation Telephone Committee, on 15th inst., agreed to recommend that application should be made for a license to establish a Corporation telephone system in the city.

Gutta-Percha and India-Rubber from Nigeria.—In the course of a series of interesting articles on Nigeria the *Pall Mall Gazette* gives us the following information:—"After ivory, rubber must lay claim to our attention as an important article of Nigerian trade. The white, sweet-smelling flowers of the rubber vine are one of the commonest sights in the forest of Nigeria. Unlike ivory, of which the output is on the decline, the trade in rubber will assuredly grow to large proportions as soon as the advent of competitive commercial enterprise into the Niger and the consequent increased demand for European merchandise on the part of the natives has provided the necessary stimulus for its development. At present the transactions in this product are, comparatively speaking, small. But both trees and vines (*Kickxia africana*, *Landolphia owariensis*, &c.) exist in plenty throughout a large proportion of the Niger territories,

Digitized by Google

and only require intelligent working—in which the attractions of immediate gain must not be permitted to spoil future prospects, as has been the case elsewhere—to yield good results. Bearing in mind the gigantic growth of the rubber industry in Lagos, the Gold Coast, French Guinea, and the Congo during recent years, there is every reason to hope and believe that, with stringent regulations against wholesale tapping, the Nigerian rubber trade will ere long become very considerable. Gutta-percha is as valuable an article of commerce, and as greatly in demand for European manufactures, as rubber itself. In Nigeria gutta-percha is collected immediately the rainy season is over, the sap at that time of year flowing more freely from the tree. In coagulating, the milk assumes a reddish tinge."

Imperial Telegraphs.—A *Times* special despatch from Simla "by Indo-European Telegraph," dated August 13th, says:—"Referring to Mr. Henniker Heaton's article in the *Times* of July 18th, and his assertion that the Indian telegraph lines may be carried across Afghanistan to Merv or Teheran, the Ameer having already sanctioned the erection of lines to Kabul and Herat, I have the best authority for stating that the Government of India are unaware of any such sanction having been given; also that Sir Edward Sassoon's belief that 'Lord Curzon had gone the length of recommending the alternative route known as the Russo-Chinese route,' for an Asiatic international telegraph is totally mistaken. The Viceroy never countenanced or authorised the expression of any such opinion. Finally, regarding the linking up of the Mergui telegraph with Singapore *viâ* the Malay States, which Mr. Henniker Heaton and Sir E. Sassoon apparently regard as a simple matter, it is necessary to point out that the Indian telegraphic authorities hold a very different opinion. They believe that the construction of such a line would be very difficult and costly, and the expense of maintenance may be judged by the fact that while the cost per mile in India is Rs.11 or Rs 12, the Tavoy-Mergui line costs about Rs.25 per line of wire. It is estimated that a line from Mergui to the Malay States and Singapore would cost from Rs.30 to Rs.35 per mile.

Telegraph Engineers in Conference.—The fourth annual conference of the Amalgamated Association of the Postal Telegraphs Engineering Department was held in the Grand Hotel, Cardiff, on Monday. Delegates were present from London, Manchester, Liverpool, Birmingham, Northwich, York, Selby, Nottingham, Newcastle-on-Tyne, Sunderland, and Cardiff.

The Telephone Service.—In the House of Commons last week, Mr. Channing, for Sir James Woodhouse, asked the Secretary to the Treasury, as representing the Postmaster-General, whether any terms had been agreed upon with the National Telephone Company as to inter-communication between the subscribers of that company and the subscribers of any competitive telephonic systems which might be set up under the provisions of the Bill now before Parliament when they should come into force; and, if so, whether he would state what those terms were.—Mr. Hanbury said if the subscribers of any competitive telephone system equalled one-half the numbers of subscribers to the National Telephone Company, then inter-communication would be free over and in the restricted area of the new licensee, or, if they numbered one-half of the whole area they would also be free. If they were equal to one-quarter and less than one-half, a charge of one penny would be made.—Mr. Provand asked what the terms would be if the number were less than one-quarter.—Mr. Hanbury replied that where the subscribers were less than one-fourth there would be a rate of three-halfpence charged for inter-communication. These cases would be extremely rare, because he certainly would not advise the Post Office to grant a license except there was a *bonâ fide* competition, which would not be the case where the subscribers were less than one-fourth.

The "All-British" Cables.—On the 10th current the Legislative Assembly of Victoria adopted a motion brought forward by Mr. Duffy, the Postmaster-General, to the effect that Victoria should join the Pacific cable scheme. One of the members urged the superior advantages of the Cape cable offered by the Eastern Extension Company, but Mr. Duffy stated that Victoria was committed to the support of the Pacific cable and it was impossible to withdraw. Mr. Gillies strongly supported Mr. Duffy, whose motion was carried by acclamation.

In Ottawa, in the speech from the Throne on the occasion of the prorogation of Parliament on the 11th, the Governor General of Canada, said: "I am glad to observe that the action of Canada in deciding to unite with the mother country and the Australian colonies in the construction of a Pacific cable has met with general approval. I congratulate you on the evidence of continued prosperity that prevails in all parts of the Dominion, and which has stimulated the formation of so many companies having for their object the development of enterprises that must tend to increase the wealth of the country." The speech concluded with the expression of a hope that Canada would long continue to enjoy the prosperity that at present prevails.

Cable Rates to South Africa.—A Reuter despatch from Cape Town says that on September 1st next the cable tariff between England and all stations in South Africa, including places in the Free State and the Transvaal, will be reduced to 4s. per word.

The West Indies Hurricane.—The Halifax and Bermudas and the Direct West India Cable Company have placed their cables at the disposal of the Lord Mayor, free of charge, for any messages relating to the Mansion House Fund. Both cables between Jamaica and Porto Rico, belonging to the West India and Panama Telegraph Company, are interrupted. This, without doubt, is due to the effects of the hurricane. It is understood that repairs will be effected before the end of this week. After having passed over Turk's Island, where no damage was done, the hurricane made itself felt in the Bahamas, the cable to those islands being also interrupted.

The West Indian Cables.—A Washington telegram to the *Standard* says:—"It will be recollected that Mr. Alger, when War Secretary, and other authorities, sustained the Western Union Telegraph Company's concession, which gives that company, with the British connections, a monopoly of West Indian telegraph business, *viâ* Cuba. But Mr. Root, his successor, will reopen the question, and will submit it to the President. He will take this action upon the opinion of Senator Edmunds, supporting the Commercial Company's claim to a right to land a cable upon its private premises in Cuba—a course now prevented by the military authorities alone.

Wireless Telegraphy.—The *Standard* says that the Admiralty have called for a report from the commanding officers of the battleship *Alexandria* and the cruisers *Europa* and *Juno* on the advantages and general results of the use of wireless telegraphy on board those vessels during the naval manœuvres. The Admiralty are so satisfied with the experiments made with the Marconi system during the naval manœuvres, that they have ordered a complete set of the apparatus to be supplied to the Torpedo Schoolship *Defiance* at Devonport, where further experiments will be tried under the direction of Commander W. C. M. Nicholson, who has made a special study of the system.

CONTRACTS OPEN AND CLOSED.

OPEN.

Aberdeen.—August 21st. The Electric Lighting Committee wants tenders for a 12 months' supply of house service and lead covered distributing cables. See "Official notices" August 11th.

Barnsley.—September 16th. Tenders are wanted for electric light wiring and fittings at the Harvey Institute, Eldon Street, for about 700 lights. See "Official Notices" this week.

Battersea.—August 31st. The Vestry wants tenders for an overhead travelling crane (hand or electric), and batteries for the electricity works. See "Official Notices" July 7th.

Battersea.—August 31st. The Vestry wants tenders for steam pipes, pumps, condensers, economiser, tools, &c., also switchboard and booster. Specifications at the office of Prof. Kennedy, 17, Victoria Street, S.W.

Birkdale.—August 19th. The Urban District Council invites tenders for the transfer of its electric lighting powers.

Blackpool.—August 21st. The Corporation wants tenders for 10 double bogie tramcars. See "Official Notices" July 28th.

Carlisle.—September 11th. The Corporation wants tenders for extension to steam, drain, and feed pipes, feed pump, and extension of economiser at the electricity works. See "Official Notices" this week.

Darwen.—August 22nd. The Corporation wants tenders for rail bonds. See "Official Notices" August 4th.

Devonport.—August 31st. The District Tramways Company invites tenders for the following contracts: Permanent way, road bed, paving and bonding of about 4½ miles of double line, overhead construction for about 4½ miles of route. See "Official Notices" August 11th.

Dundee.—August 23rd. The Council wants tenders for the overhead line equipment and rail bonding of the Perth Road and Lochee tram routes. See "Official Notices" August 4th.

East Ham.—September 9th. The Urban District Council wants tenders for combined electric light and traction plant, engines, generators, overhead line equipment, cars, switchboard, arc lamps, &c., water-tube boilers, condensers, and other steam plant, electric light cable. Mr. W. C. Ullmann, The Limes, White Post Lane, East Ham, is the Council's electrical engineer. See "Official Notices" August 4th.

(*Continued on page* 279.)

A "FIN-DE-SIECLE" MACHINE SHOP.

By FRED. BATHURST, A.M.I.E.E.

To English readers the above title would, under present conditions, suggest that this article deals with a recently installed American factory, or else an English workshop re-modelled on American lines and equipped with the latest types of American tools, since for up-to-date machine shop lay-out with scientific and economic production, it is only too seriously true that at the present moment we have to look to U.S. practice for the best examples.

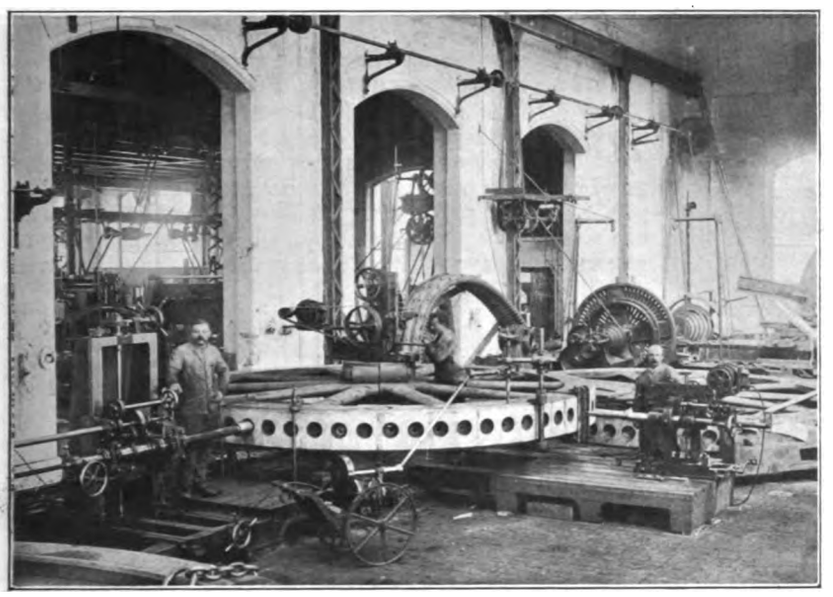

Fig. 1.

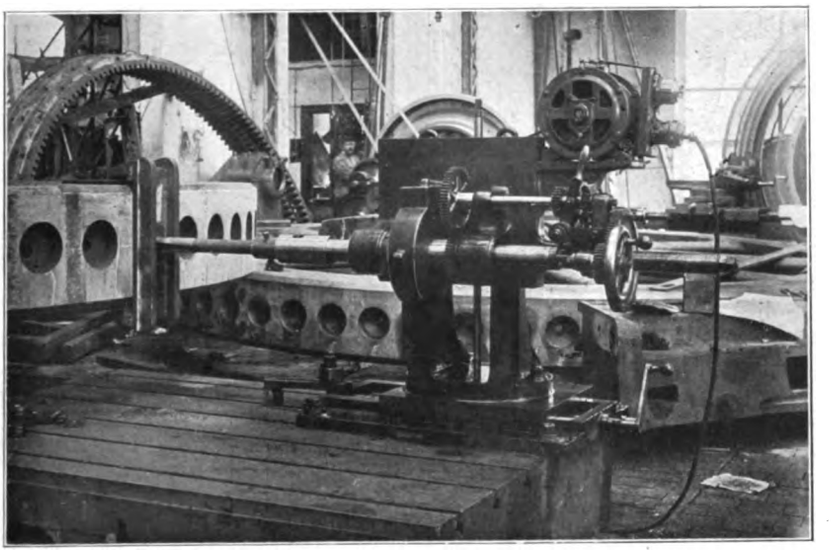

Fig. 2.

It is with pleasure, therefore, that one finds in the centre of Europe, at Prag-Vysocan, in Austria (midway between Vienna and Berlin), the dynamo machinery factory of Kolben & Co., or, to give it its full Bohemian title, the "Elektrotechnická Akcrová Spolecnost drise Kolben a Spol." It is thought the following description and illustrations of machines found in this shop will prove that there is near at hand at least one instance of as perfect a combination of European and American workshop practice as can be desired.

In describing a modern machine shop, designed for the purpose of manufacturing all sizes and types of dynamo-electric apparatus, it is only to be expected that we should find the advantages of electric power transmission fully appreciated, although rarely so fully and completely utilised as in this particular instance. An up-to-date factory manager having to consider the question of alterations or extensions to an existing plant, must by this time thoroughly recognise the advantage and economy arising from the use of electrical transmission of energy by means of small flexible and easily installed copper wires, instead of following the old-time practice of power transmission with its shafting and belting from the main engine, necessitating fixed and heavy runs of steel shafting with a consequent limitation as to the design of the shop and the position of the machine tools.

With electric transmission the shops can be arranged:—

1. Just as required in the natural process of production and without regard to the lay-out of the building.

2. Extension can be effected and additional machines laid down in any direction without any regard to driving power and the shafting runs.

3. Great saving in the wear and tear of the driving shafting (oftentimes from 30 to 60 per cent. of the total power required in the factory) can be effected by applying electric power direct to the larger or special portable tools, whilst smaller machines are separately driven in groups from short lengths of countershafting.

Thanks to the high state of development and mechanical perfection that has been reached in respect to continuous current motors and generators, many factories can now be found in which the above advantages have been seized upon, and descriptions of such plants are no longer new.

The plant of Kolben & Co., although comparatively small by reason of its exceptional design in respect to the horse-power required, is a unique and up-to-date exemplar of three-phase current electric power distribution, a type of practice which has been comparatively neglected in England until recently. The writer's opinion is that examples of three phase work in England have been few, and our electricians have not acquainted themselves sufficiently with foreign and Continental practice, so

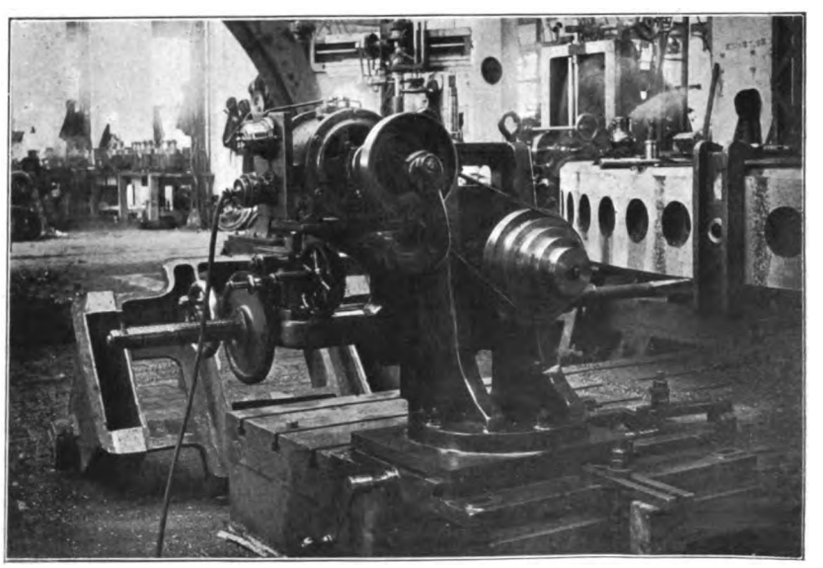

Fig. 3.

Digitized by Google

that they have failed to appreciate the advantages and possibilities of this system of electric supply.

The approaching visit of the I.E.E. to Switzerland may, it is anticipated, offer an opportunity of seeing the successful and practical use of three-phase plants, and will doubtless lead to their more general development in England.

It may, however, be taken for granted at once that, for any power installation requiring a number of motors for varied applications, and where the total capacity required amounts to 100 H.P., under most conditions a three-phase plant will be found more economical both in first cost

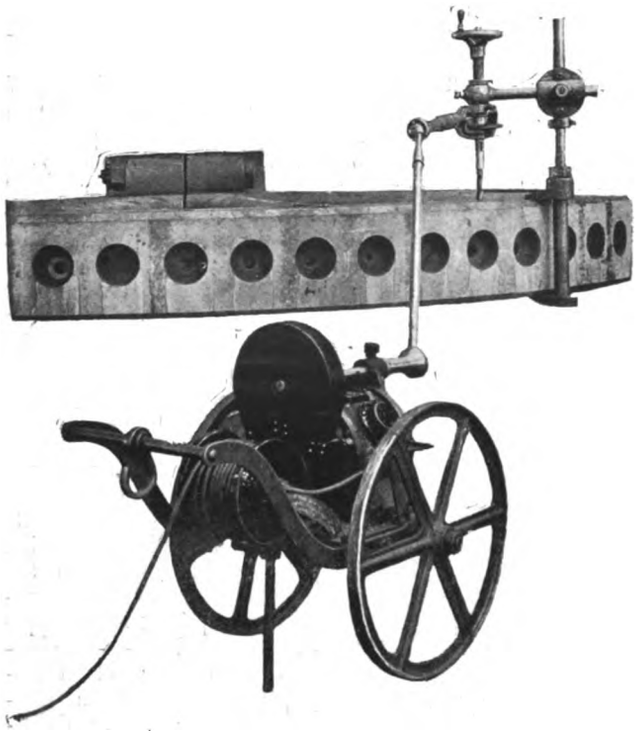

Fig. 4.

and in maintenance than a continuous current installation. The comparative absence and unimportance of the motor starting and regulating boxes, and the greater impunity with which the three-phase motors can be handled by unskilled and non-technical workmen alone counts greatly in favour of this system, but this point is best brought home by actually seeing a few plants in operation rather than by discussion.

Having determined the prime source of power, and chosen the method of distribution by which the power is to be advantageously applied, the factory manager, in order to reach an ideal lay-out, has to provide high-class tools which will give

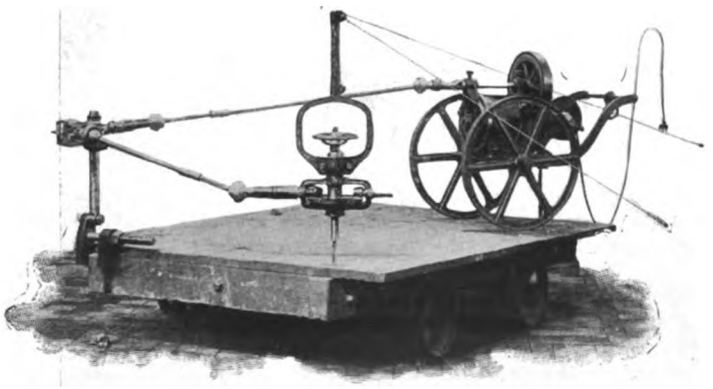

Fig. 5.

a large output at low cost production and within a minimum of time. The work provided must employ each tool upon its standard work for as many hours as possible during the working day so that the tool may fully earn the interest on its first cost. Floor space must be occupied as economically as possible.

It is problems such as these that Herr Emil Kolben set himself to work out in connection with this factory. Probably very similar conditions present themselves in almost every factory, but certainly in a rapidly-growing and developing industry like that of dynamo machine manufacture, although the utmost care and discretion may have been exercised in the selection and arrangement of the tools, a time comes when the castings and parts to be operated upon grow too large for the existing appliances, and the management has to face the solution of newer and more difficult problems. It is in meeting this condition that the works of Kolben & Co. appear to have attained most complete success, so that to-day this factory must be counted amongst the few that can readily undertake and execute any and all classes of electrical work that can be called for or that progressive development may dictate. The unexpectedly rapid increase in kilowatt capacity of the generators required for electric light and traction work brought into the shop heavier and still heavier

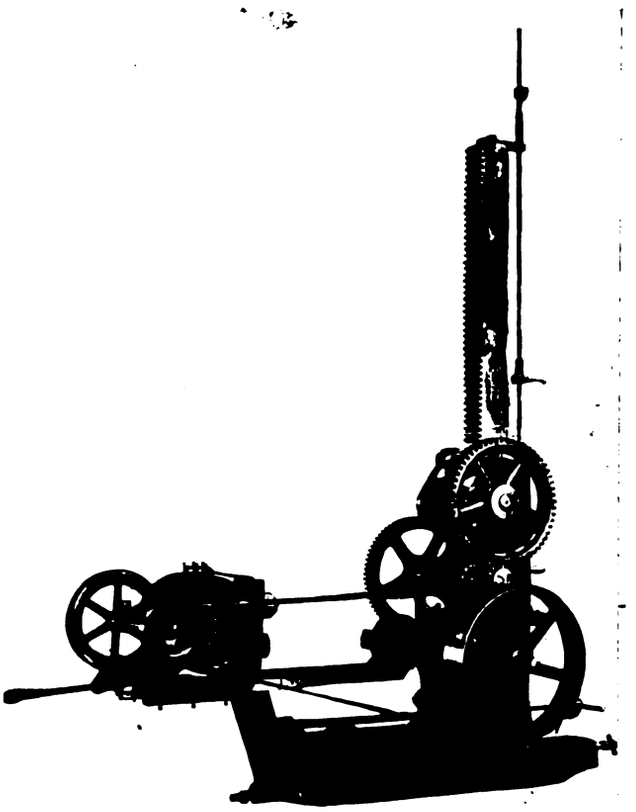

Fig. 6.

castings, whilst the adoption of the fly-wheel type of multipolar generating machines so increased the size and shape of the castings handled as to necessitate an almost complete reversal of the practice the shop had been laid out to meet.

The castings grew larger and larger until they reached the practical limit for satisfactory handling. When castings of fly-wheel shape grew from 2 and 3 feet to 12 and 20 feet diameter, and increased in weight from 4,000 lbs. to 80,000 lbs., it was found easier to bring the tools to the work, instead of taking the work to fixed tools.

The main object of this article is to bring the illustrations and descriptions of these specially designed portable tools before the readers of the Electrical Review, so as to show the comparative ease with which a machine shop can be re-equipped, to enable it to undertake the production of machines of the largest size with a comparatively small fresh outlay of capital. Incidentally, also, it will be noticed how completely and efficiently three-phase motors of any size can be applied to meet the requirements of machine tools.

Fig. 1 shows four processes, *a*, *b*, *c*, *d*, being carried on at one and the same time upon a 16-foot diameter magnet wheel (weight 46,000 lbs.), designed for use in a 1,000 H.P three-phase alternating current generator.

Digitized by Google

The illustration sufficiently indicates the difficulty that would be entailed in handling such a large-sized piece of work, if it had to be taken from tool to tool for each process, and by comparison shows how conveniently the small portable self-contained motor tools can be arranged around it, so that horizontal drillings in two sizes, side drillings, and key seating operations can proceed together.

Instead of choosing a position with respect to the countershafting available for tool driving, the casting is dropped down anywhere in the shop, and a flexible electric cable brought to the motor of the portable tool from the nearest wall plug. In this particular case, the work has been placed so that it can be operated upon (process *a*) by a fixed horizontal boring tool (shop-driven by a 6 H.P. three-phase motor) which has to make the 64 12-inch diameter holes for the magnet cores. By arranging three other portable tools around the casting, economy of floor space, as well as of labour, naturally follows, and although three workmen can be seen in the picture, only two are needed to tend the four tools at work.

Figs. 2 and 3 show in detail the tool by which (process *b*) the side boring of a hole 2½ inches in diameter inside the 12-inch hole in the cast-steel frame is carried out. This portable horizontal boring machine weighs, complete with motor, only about 900 lbs., its approximate overall dimensions being: height, 3 feet; width, 2 feet 6 inches; length, 4 feet 6 inches without boring tool.

The machine is arranged on a base plate, which can be clamped or bolted to the shop floor or a convenient tool bed. The body of the machine is mounted on a sliding bed in such a manner that it can swivel completely around or move along it, so that the boring mandrel can be readily faced up toward or adjusted to the work. A three-phase 1-H.P. motor bolted to the frame casting provides sufficient driving power, a cone pulley on the motor shaft driving by belt a counter cone, which is connected through screw gearing to the boring shaft. The gearing can be thrown in or out by the workman as he desires, whilst the boring shaft has a self-governing screw feed. With this machine holes of any size up to 3 inches diameter can be readily bored out. The approximate cost of the complete tool is about £70.

Fig. 4 shows the detail of the Universal portable truck drill which is seen at work in fig. 1 (process *c*), making a side hole for a 1-inch bolt. This tool weighs, complete, about 650 lbs., and, including the waggon, has overall dimension as follows: Height, 2 feet; width, 2 feet; length, 3 feet 6 inches. When fitted complete with flexible shaft, drill holder outfit, connecting cable and winding drum, its cost is £80.

It consists of a two-wheel carriage supporting a 1-H.P. (three-phase or other type) motor driving by single reduction a geared countershaft which operates the flexible shaft. The whole machine is balanced in such a manner that when it is necessary to do drilling at a height more than 5 feet from the ground (the limit of the flexible shaft), as may be required for the inside of large generators (or in another condition, as for roof or bridge work), the whole tool is swung into the air by means of a crane, and the drilling shaft remaining horizontal, drilling can be proceeded with in this position. Holes up to 1½ inches diameter can be made by this machine.

Experience proves that the possibility of operating this machine whilst it is suspended in mid-air is very useful in the case of large generators, the necessary hole being made whilst the work is *in situ*; without such apparatus the work would have to be laid over on its side upon the floor of the shop, and brought with difficulty under the ordinary drilling press. It is obvious that this truck drill when fitted with a special head-piece can be most usefully employed inside boilers or similar hollow work, as well as finding an invaluable application in respect to flat tablets and marble slabs used in electric switchboard work. The latter application is shown in fig. 5.

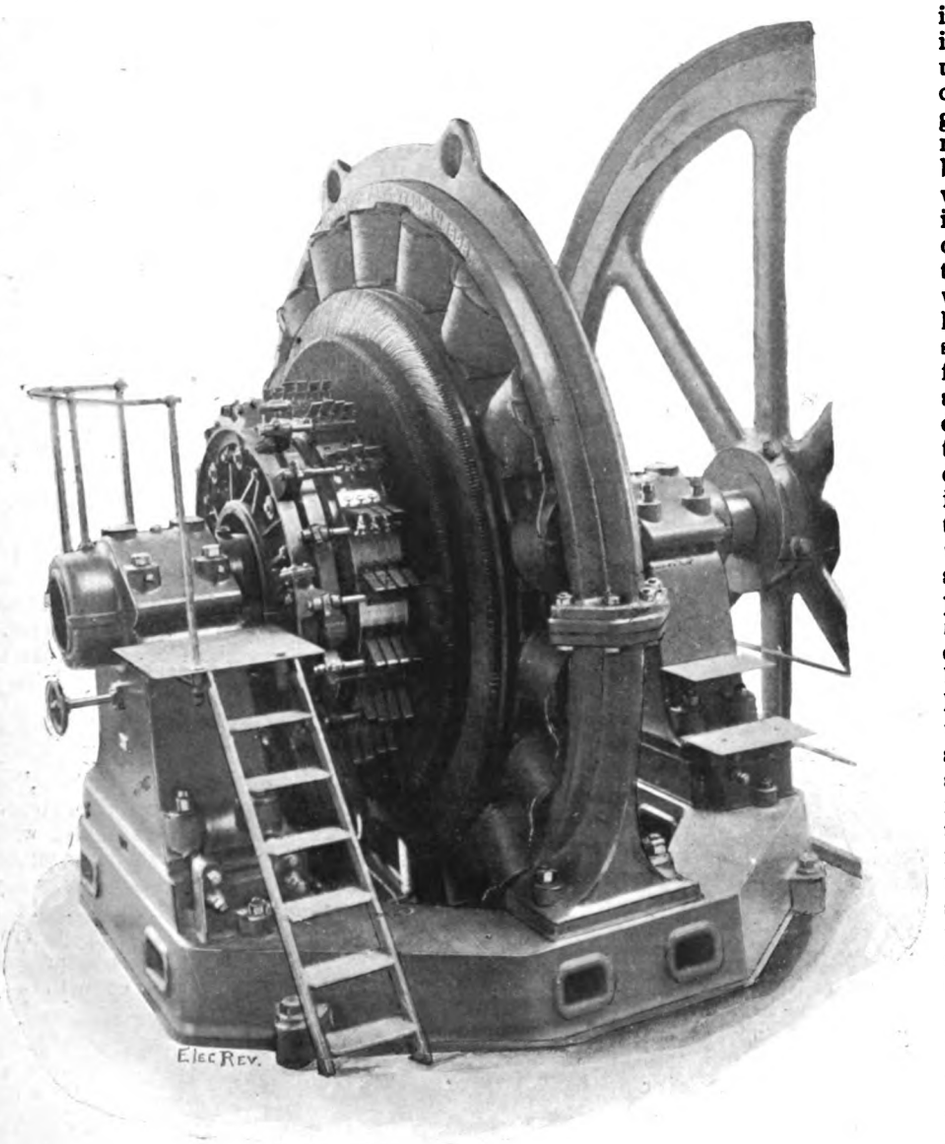

Fig. 7.

Fig. 6 shows in detail the American type of key-seating machine, driven by its self-contained ½ H.P. three-phase motor, which is carrying out process *d* in fig. 1. This portable combination tool, weighing about 1,800 lbs., is one of the most useful machines to be found in Kolben & Co.'s shops. Whilst dynamo manufacturers in England are mostly employed upon two, four, and six-pole generators, having comparatively high-speed small diameter armatures, Continental practice in respect to generators for outputs above 200 KW. has developed through "many poles," until to-day the most favoured type is a direct-connected slow speed bar-wound armature of large diameter, enclosed by a field magnet often containing 20 or more poles (see fig. 7, showing the design of a 400-KW. continuous current generator running at 90 revolutions and having 18 poles). This constant increase in the diameter of the armature required a continual increase in size of the swinging arm of the slotting machines necessary for cutting

Digitized by Google

the key-way for the engine or driving shaft, until the limit of a practical tool was reached.

The race between the size of the work and the tool required for it, having been decided in favour of the work, we now find this comparatively small tool, having overall dimensions, height 8 feet, width 3 feet, length 6 feet, uniformly employed upon all the larger size pulley or wheel-shaped castings required for armature spiders. The portable

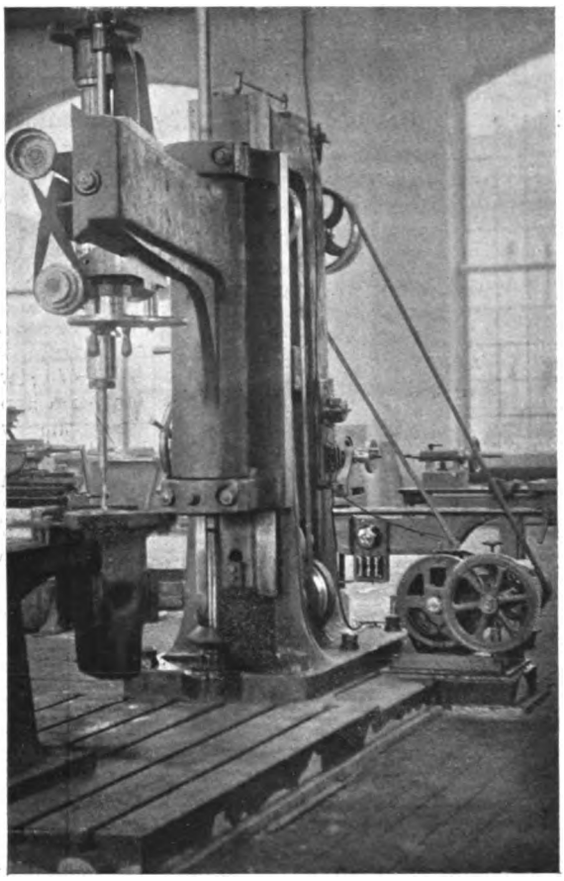

Fig. 8.

tool has the advantage that the shop crane readily transports it to the particular casting to be operated upon, and being fixed in position thereon, the key-seating process can proceed at the same moment as, and without hindrance to, other essential operations, making a great saving and convenience in the handling of the castings, as well as permitting a saving in the time required for finishing them.

Instead of the practice usually followed in slotting machines, by which the tool head in making the cut is forced downwards into the work with the tendency to compress or bend the tool holder out of position (necessitating considerable stiffness and strength of tool arm and body), advantage has in this case been taken of the general lightness of the design (required for portability) to reverse the action of the tool, and employ the tool head as a *draw bar* under tensile or pulling stress instead of under compression. A special clutch gearing is also used, so that the tool returns from its work four times as fast as its normal cutting speed, this movement, as well as the feed, being provided for automatically.

The ½ H.P. motor is provided with single reduction gear and belt drives on to the tool mechanism, so that the slip of the belt partially compensates the strain on the tool mechanism, as the tool enters or leaves its work. The motor being mounted on a sliding baseplate, a belt tightening attachment provides any desired adjustment. This tool cuts a key-way in shaft bores of any size from 4 inches to 20 inches diameter, as deep as necessary, from ¾ inch to 4 inches wide. The approximate cost of such a tool complete is £200. It is obvious that such a convenient tool has a wide range of application in other machine and metal working shops.

Fig. 8, showing a radial drill driven direct from its independent shop motor can be advantageously referred to at this point, as showing the difficulty that the ordinary drilling as well as keyseating tools present by reason of their clumsy overhanging swinging arms. After seeing in operation the drilling and boring tools shown in fig. 1, no one will want to arrange a large casting of awkward shape underneath tools of the swinging arm type. The tool shown has a 7-foot swinging area, and is belt-driven through single reduction gearing by a 3-H.P. motor secured to the same bedplate. This tool is now relegated to its proper use, that of drilling holes up to 3½ inches diameter in large base plates or other flat castings of large area. At the back of the drill part of the tool head and bed of a small lathe may be seen, together with the simple starting and regulating switch, by which its self-contained three-phase motor is controlled.

Fig. 9 gives a good idea, by comparison with the relative size of the men at work within it, of the diameter of the pieces of work that are being dealt with in the Kolben factory. It illustrates the assembling of the stationary armature for a three-phase 1,000 H.P. generator. This armature frame is 19 feet inside diameter, and has a finished outside diameter of 25 feet. Its approximate weight (finished) is 60,000 lbs., whilst the generator, assembled complete, weighs 140,000 lbs. These figures may be considered sufficiently eloquent in themselves to save allusion to the fact that it is better to let such pieces remain on the shop floor as much as possible in one position, and bring portable tools to them, rather than endeavour to take them around the shop to large fixed tools. The four men seen within the ring have their hands fairly full of hard work, for they have to assemble 26,000 lbs. of thin sheet iron, consisting of 11,500 segments (seen as sectional stampings), and the winders, who occupy their position later, have to handle a considerable weight of copper in arranging in the 384 peripheral (slotted) holes, 192 carefully insulated coils. Always having a thought towards the saving of floor space, it is no uncommon sight in this shop to see two, or even three, of these armature frames being assembled one within the other, and yet find that the nine or ten men employed have plenty of working room.

A further note in connection with the assembly of this armature may be of interest to English manufacturers who are still mainly in the "japan pasting," or perhaps in the "paper punching" stage. In ordinary practice, the 11,500 iron segments would have to be assembled with an equal number of separate and similar tissue paper punchings, the work of assembling these frail sheets being really more trying and fatiguing than the iron segments. In fact, the difficulty and annoyance arising from the paper sheets has convinced many designers that equally good mechanical and magnetic "insulation" can be obtained with a japanned disc, in

Fig. 9.

spite of the incidental difficulty of effective painting and drying. Careful and complete tests have convinced the engineers of the Kolben Works that "paper" separation is to be preferred, provided always that wood-pulp tissue paper, which will bear subjection to great heat and pressure without charring, is chosen. The difficulty and extra time required for stamping and assembling the paper has been overcome by designing a machine which pastes every sheet

Digitized by Google

of iron with a complete facing of paper, so that the one punching operation for making the sections cuts out the stamping ready papered for assembling. With this machine, a modified form of printing press, two men can in a 10 hours' day cover 6,000 feet of iron sheeting 4 feet 6 inches wide without any difficulty. The immense saving of labour which this machine effects is further supplemented by advantages which follow in assembling, for with pasted sheet armatures the holes or slots in the disc or segment, line up quite truly without the necessity of "gouging out," and leave a larger and truer space for the winding, permitting a considerable percentage increase either in copper cross-section or for the insulation of the wire or bars.

(*To be continued.*)

CONTRACTS OPEN AND CLOSED.

OPEN.

(*Continued from page 274.*)

Germany.—Tenders are at present being invited by the Frankfort-am-Main Municipal Tramways Committee for the supply of 200 steel tyres and 40 sets of wheels and axles for electric tramcars. Tenders to be sent to the Betriebs Direction der Städtischen Strassenbahn, Frankfort-am-Main (Bockenheim), whence particulars may be obtained.

Glasgow.—August 21st. The Corporation wants tenders for the supply of switchboards, copper bus bars, and electricity meters. See "Official Notices" August 4th.

Hackney.—September 12th. The Vestry wants tenders for four sets of direct current steam dynamos (either high or low speed). See "Official Notices" August 11th.

Hampstead.—The Vestry invites tenders for the extension of its electric lighting station, and is spending £30,000 on new machinery there.

Ilfracombe.—September 25th. The District Council wants tenders for boiler plant, engine plant, dynamos, condensers, switchboard, mains, lamp-posts, accumulators, meters, crane, buildings, &c. See "Official Notices" this week.

Ingleton. — The Ingleton Electric Light and Power Company wants tenders for the supply of dynamos, switchboards, batteries, and wiring. See "Official Notices" August 4th.

Leeds.—August 30th. The Tramways Committee wants tenders for the electric lighting of the car sheds, Kirkstall Road. See "Official Notices" this week.

Malmo.—September 1st. The Gas Works' directors want tenders for the erection of electricity works for the city. Particulars on application to the clerk of the Gas Works (deposit 12s).

Manchester.—August 23rd. The Baths, &c., Committee is inviting tenders of an electric light installation for the new Islington Baths and Public Halls. Specifications from the general superintendent, Osborne Street Baths.

Motherwell, N.B.—August 18th. The Commissioners invite tenders for machinery and works in connection with the proposed electric lighting of their town. See "Official Notices," July 28th.

Perth.—August 28th. The Commissioners want tenders for boilers, condensers, steam dynamos, switchboard, underground mains, and accessories. See "Official Notices" July 28th.

Poplar.—September 6th. The Guardians wants tenders for high speed engine and dynamo, electric motors, Lancashire boilers, economiser, and other plant, as briefly particularised in our "Official Notices" this week.

Portugal.—September 6th. Tenders are being invited by the municipal authorities of Cascaes, Portugal, for the concession for the electric lighting of the town.

St. Annes-on-the-Sea.—September 11th. The Council wants tenders for high speed engines, continuous current dynamos, and balancing booster, for electric lighting. See "Official Notices" this week.

St. Mary, Battersea.—August 31st. The Vestry wants tenders for steam pumps, pipes, condenser, economiser, &c., switchboard, and boosters. See "Official Notices" July 28th.

Southport.—The Corporation wants tenders for the supply and laying of tram rails, points, crossings, bonding, permanent way; also overhead equipment, including poles, wires, &c. See "Official Notices" August 11th.

Sunderland.—The Corporation wants tenders for four 270-kw. three-crank direct current steam dynamos, and two surface condensers and cooling tower. See "Official Notices this week.

Sydney (N.S.W.).—November 3rd. The Municipal Council of Sydney is inviting tenders for the construction and erection of a refuse destructor for treating 60 tons of refuse per day (24 hours).

CLOSED.

Bootle.—The Town Council has placed a contract with Messrs. T. Parker, Limited, for the necessary station plant for the purposes of electric traction, according to Mr. Miller's specifications, at £2,353; also with Messrs. R. W. Blackwell & Co. for poles, bracket arms, span, trolley, guard, and other wires, street boxes, &c., necessary for the complete equipment of the overhead trolley line along Stanley Road from the south to the north boundary of the borough, with a branch line along Strand Road to Derby Road; also with Messrs. Callender's Cable Company for the supply and laying of traction feeders at £1,228.

Bridgwater House.—Sixteen tenders were received for the wiring of Bridgwater House state rooms, and that of Messrs. W. J. Fryer & Co., Limited, of Sloane Square, has been accepted.

Glasgow.—We understand that the Corporation Tramway Committee on Tuesday considered tenders for supplying engines for the Glasgow electric tramways. Mr. Parshall, the electrical engineer, strongly recommended acceptance of the tender of Messrs. E. P. Allis & Co., of America, who offered engines for £114,554, and by seven votes to six this tender was accepted. Messrs. Harvey and Williamson, of America, tendered at £160,000 while Messrs. D. Stewart & Co. tendered at £54,800, but offered a lighter engine.

Hapton.—The Parish Council recently invited estimates for lighting the township electrically from September this year to April next year, and the tender of Messrs. Simpson Bros., a local firm, at £118 15s. has been accepted.

Islington.—The Guardians have accepted the tender, £192, from Messrs. Kirk & Randall for telephonic communication at Highgate Hill.

Pembroke (Ireland).—The following is a list of the tenders submitted to the Commissioners for electrical plant, &c.:—

Section K.—For Condenser, Air Pump and Feed Heater.

Name of firm.	Amount of tender.
Worthington Pumping Engine Company	£535 0 0
Wheeler Condenser Company (accepted)	556 0 0
Worthington Pumping Engine Company (alternative)	589 0 0
R. W. Blackwell & Co.	758 9 6
Frederick Nell	854 0 0
John Spencer, Limited	981 6 0
Mirrlees, Watson & Yaryan	1,052 0 0
Klein Engineering Company	1,365 0 0
W. H. Allen, Son & Co.	1,393 0 0
George Wailes & Co.	1,810 0 0
G. S. Derriter	2,192 12 0

Section L.—For Water Cooling Plant.

Korting Bros.	£442 10 0
Wheeler Condenser Company	631 15 0
Klein Engineering Company (accepted)	707 0 0
Worthington Pumping Engine Company	718 0 0
Isaac Storey & Sons	806 0 0
John Spencer, Limited	850 0 0
Klein Engineering Company (alternative)	877 0 0

Rathmines and Rathgar (Ireland). — The list of tenders for electrical equipment submitted to the Commissioners is as follows:—

Section K.—For Public Arc Lamps and Posts.

Name of firm.	Amount of tender.
Veritys, Limited (accepted)	£3,042 8 6
The Electrical Company, Limited	3,124 3 6
Calvert & Co.	3,291 16 0
Oliver & Co.	3,376 2 0
Johnson & Phillips	3,462 2 0
W. Lucy & Co., Limited	3,463 10 0
The Gilbert Arc Lamp Company, Limited	3,491 10 0
The British Insulated Wire Company, Limited	3,524 6 0
The Gilbert Arc Lamp Company, Limited (alternative)	3,740 0 0
Crompton & Co., Limited	3,747 17 0
Cotsworth Arc Lamp and Electric Lighting Synd'e, Ltd.	3 761 16 0
Brockie-Pell Arc Lamp, Limited	3,889 19 6
The Walsall Electrical Company, Limited	4,441 18 0

Section L.—For Generating Station, Pipe Work, Feed Tank, Feed Heater, &c.

R. W. Blackwell	£1,789 9 0
John Spencer, Limited (accepted)	1,997 18 8
George Wailes & Co.	2,134 0 0

Section M.—For Condenser and Air Pump.

The Wheeler Condenser & Engineering Co. (accepted)	£413 0 0
The Worthington Pumping Engine Company	415 0 0
Frederick Nell	439 0 0
John Spencer, Limited	493 10 0
Mirrlees, Watson & Yaryan Co., Limited	815 0 0
Klein Engineering Company, Limited	895 0 0
W. H. Allen, Son & Co.	1,067 0 0
Bow, McLachlan & Co.	1,250 0 0
George Wailes & Co.	1,250 0 0
G. S. Derriter	1,901 12 0

Section N.—For Water Cooling Plant.

Korting Bros.	£417 10 0
Calvert & Co. (exclusive of pipes)	550 0 0
Wheeler Condenser and Engineering Company	656 15 0
Worthington Pumping Engine Company	725 0 0
Isaac Storey & Sons	781 0 0
John Spencer, Limited	825 0 0
Klein Engineering Company, Limited (accepted)	847 0 0
Bow, McLachlan & Co.	925 0 0

Sunderland.—The Council last week sealed the contract with Messrs. Dick, Kerr & Co. for permanent way, overhead equipment, and electric cars for the new tramway system at about £126,618. The chairman of the Tramway Committee said that the preparation of the Chester Road route was to be commenced at once, and the permanent way finished by December 31st next, and it would be available for horse trams during the reconstruction of the Hylton Road section. The existing routes were to be commenced as soon after January 1st next as was practicable, and the contractors agreed to complete the Roker, Christ Church, Hylton, and Chester Road sections by June 30th next—ready for electric traction. The remainder, if possible, would be finished by that date, but at the latest by August 31st, 1900, or the contractors would have to pay a penalty of £10 per day. There was also a penalty for the non-delivery of cars. Under the Act the Corporation had five years in which to do the whole of the work, but the committee was anxious to make a smart change from the old to the new systems.

The Town Council has accepted the tender of Messrs. G. and J. Weir, Limited, for two boiler feed pumps, and that of Messrs. Galloway, Limited, for four boilers and economisers. New feeder cables are to be laid for Hendon Road district at £1,550. Three automatic cut-outs for the new steam dynamos are to be obtained at £60, and indicators, meters and house fuses at £300 for stock. An extension of mains is also to be carried out to Roker Avenue and Dock Street Chapel at £587.

NOTES.

Personal.—Mr. Hugh Erat Harrison, B.Sc., principal of the Electrical Standardising, Testing, and Training Institution, has been appointed by the Board of Trade electric inspector to the Corporation of Tunbridge Wells.

A Glasgow evening paper says that ex-Prof. Jamieson has been called out to Cape Town to give expert evidence in a big case between the Cable Company and the Corporation running electric cars, the latter being alleged to affect adversely the working of the delicate telegraphic instruments connected with the cable.

We notice in the *Journal Officiel* of the 11th inst. that the French Government has granted the grade of Chevalier de la Legion d'Honneur to M. Paul Wallerstein, the administrator of the Société Industrielle du Téléphones, under whose personal direction was laid the Brest, Cape Cod, and other cables of the Compagnie Française du Cables Télégraphiques. The distinction conferred on M. Wallerstein will give pleasure to his many English friends.

Mr. O. M. C. Heyl informs us that he has resigned his position as district manager and engineer to the Newcastle-on-Tyne branch of Messrs. English Industrials, Limited, and has joined the engineering staff of the Allgemeine Electricitats Gesellschaft, of Berlin.

Mr. A. H. Roe has been appointed departmental electrical engineer to the Bradford Corporation, in succession to Mr. C. A. L. Prussmann, whom he formerly assisted, and who has gone to Doncaster as Corporation electrical engineer.

Mr. C. A. Midgley has resigned the post of chief assistant electrical engineer at Wakefield, to take up the post of city electrical engineer at York. Mr. H. T. Lee takes Mr. Midgley's place at Wakefield.

Appointments.—Fifty-five applications were received for the post of assistant engineer to the Bournemouth and District Electric Supply Company, and Mr. F. E. Benest, at present with Messrs. Siemens Bros., has been appointed.

Train Lighting—Gas v. Electricity.—In a recent article on "Lighting Railway Carriages by Electricity," the *Engineer* said that the total weight of the electric plant is less than would be required for a gas lighting system affording the equivalent amount of light. This has drawn from Pintsch's Patent Lighting Company a correction, stating that the weight of the electric light apparatus is rather more than double the weight of the gas lighting apparatus, the latter giving a superior light. The editor of our contemporary has wisely asked the writer and also Messrs. Stone & Co., of Deptford, the owners of the Gill train electric lighting system, to give actual weights of their respective systems. This information, if forthcoming, should be interesting.

The Opposition to the Pacific Cable Scheme.—At the present moment, when all who have the best interests of Great Britain and her dependencies at heart, and who are not inspired by motives of self-interest, are very anxious that the Pacific cable scheme should enter the sphere of active operations, it is worth while noting the tactics of the opposition group of cable companies. The only reply they received to their protest was a snub, if we may put it curtly, from the lips of Government Ministers. Perhaps this was responsible for raising their ire, for no stone has been allowed to gather moss which by rolling would postpone still further the great scheme. Now that there seems to be some prospect of a settlement, the tactician has been secretly at work upon further details in the opposition programme. To fill certain works with orders to occupy them for a long time ahead so that they would be unable to carry out the Pacific contract, to purchase gutta-percha in large quantities, thereby restricting the market and stiffening the price, these have been some of the the methods adopted to serve the desired end. The mere knowledge of these facts should be sufficient to place the Government officials upon their guard. We will not devote too much space to discussing the legitimacy of the procedure, but we would add that others also have had a watchful eye upon submarine cable material, and there are other works, who, we believe, are well able to fulfil the Pacific contract with satisfaction and expedition. The activity in submarine cable work just now is noteworthy. We believe it is a fact that about 14,000 miles of such cable are either on order or contracts are ready to be let, and the greater part of it may, as hinted above, be gathered into one net. Our representative called on one of the manufacturers for confirmation of the above rumour, which had reached us through other channels, and was informed that although the rumour is correct, generally speaking, some of the particulars are erroneous. The manufacturer hazarded the opinion that a well-known Company would probably use its undoubted influence in the cable ring, and would fan the forest fire which is apparently causing a stampede among the managers of the Globe Telegraph and Trust Company and its satellites. As a journal representing trade interests, we approve of reserve funds, hitherto invested in Government stocks and railway debentures, being realised and employed to promote fresh work, but such action should be taken deliberately and after mature consideration, and should not convey the impression that the copper dam has burst on the appearance of the Pacific cable banshee.

A Fair Hearing Wanted for the Trolley.—The current issue of the *Railway World* contains a timely note regarding the objection frequently raised of late by opponents of the overhead trolley system that it is not giving satisfaction in America. We reproduce the following on the point, which may be of interest both to Prof. Kennedy and the London County Council :—

Rumours of dissatisfaction with the trolley system in America are very greatly exaggerated. Complaints are occasionally made, but these are generally due to particularly unsightly street work, such as no one would propose to repeat in this country. Take the United States as a whole, and leaving out of the account the cities of New York, Chicago, and Washington, it may be said that the trolley system is universally approved by both the public and the tramway companies. Of the 16,000 miles of electric railways, all but a very small proportion are trolley lines. Visitors to America who have not penetrated further than New York, may return and write to the newspapers that the trolley lines are being replaced by the conduit system, but the fact is that no trolley lines in America have as yet been removed, nor are there any projects for conversion. In New York and Washington, and in some streets in Chicago, the overhead wire has never been admitted, largely because older forms of mechanical traction rendered less necessary the immediate adoption of the trolley. Elsewhere the trolley has met with approval, and it has done excellent service. History will repeat itself here as fast as new lines are opened, and corporations that have decided to instal the trolley system have no occasion to reconsider the question. The Manchester Council, which has been urged to send a delegation to America to investigate with a view to reconsideration of the determination to adopt the overhead wire, has made no mistake in declining to accept the suggestion. Its advisers perfectly understand the situation abroad, and at the present stage they recognise that, all things considered, the trolley system will most completely meet the requirements of the city for cheap and comfortable transport.

Obituary.—It is with great regret that we record the death of Sir Edward Frankland, who was celebrated for his great work in the field of organic chemistry. He was also an eminent authority on water analysis, particularly in connection with the London water supply. He was the Government water analyst. For many years he held the post of Professor at the Royal College of Chemistry (School of Mines), retiring therefrom in 1885. He had previously acted as Professor of Chemistry at the Royal Institution, at St. Bartholomew's Hospital, and at Owens College, Manchester. In 1865 the Royal Society awarded him the Royal Medal for his researches into the new series of organic bodies containing metals. His "System of Notation," published in the *Journal of the Chemical Society*, is said to have cleared up a great many points in organic chemistry. His "Lecture Notes for Chemical Students," published in 1876, have had a large circulation, while he also published "Experimental Researches in Pure, Applied, and Physical Chemistry," and several hand-books. He has occupied the presidential chair of the Chemical Society and the Institute of Chemistry, and he was also a member of numerous English and foreign scientific societies. Sir Edward was born in 1825, so was 74 years of age. He will be well remembered in electrical circles as a member of the Committee of the Electro-Harmonic Society, at whose concerts he was frequently present in the capacity of chairman.

It also falls to our lot this week to chronicle the death of another very eminent worker in the school of chemistry. Prof. R. W. Bunsen, F.R.S., died at Heidelberg, on Wednesday morning, in his eighty-ninth year. So far back as 1836 the deceased professor succeeded Wöhler as professor of chemistry in the Cassel Polytechnic School, and some 16 years later, in 1852, he was appointed to the chair of experimental chemistry at Heidelberg. This appointment he held until 1889, when he resigned. Meanwhile honours were conferred upon him from all directions for his remarkable investigations and discoveries, but it seems from what we read in the *Times* that beyond all the orders and decorations of monarchs he valued the foreign fellowship of the Royal Society, to which he was elected in the year 1858, and the recognition of his work by numerous other scientific societies. The Royal Society in 1860 awarded him the Copley medal, and in 1877 he and Kirchhoff were jointly made the first recipients of the Davy medal. The Bunsen gas burner has made his name familiar in every household, while the Bunsen voltaic battery is known to every electrical student. From the list of his very numerous investigations we may select for brief mention the chemistry of blast furnace gases, actinometry, and the chemical action of light, but his greatest work is considered to be that undertaken with his colleague Kirchhoff on spectrum analysis. The work of these two professors placed analysis by spectrum observation on a sound and firm experimental basis. At the time of his death Bunsen was spending his last days in well-earned retirement at Heidelberg.

Standard Electric Wiring Rules.—Mr. W. G. McMillan, the secretary of the Institution of Electrical Engineers, is sending out the following circular on this very important subject. The recent papers and discussions at the Institution on the desirability for securing uniformity, or something approaching thereto, will be well within the minds of our readers:—

> You are no doubt aware that members of our profession who wire premises for the supply of electrical energy have for some time past been complaining that they are harassed by the multiplicity of existing rules. It is generally admitted that the rules, framed by a committee of experts representative of the special interests involved, and published by this Institution, have been accepted by a large number of central station, municipal, and consulting engineers, inspectors for fire insurance offices, and others.
>
> The council of this Institution has appointed a committee to inquire into the reasons, if there be any, which prevent the Institution rules being accepted by everyone as the standard. The committee feel that it is very probable that most of the authorities who are using other rules might be induced to accept those of the Institution if these latter were modified in some particulars. As a first step, therefore, towards the standardising of rules, the committee are anxious to receive any reasonable suggestions that may be offered with the above object. I should be glad if you would kindly let me know whether you would, if called upon, be willing to assist the committee with your advice and criticisms on the existing rules, and, if so, I am directed to inform you that the committee will prepare and forward to you a paper of questions, to which they will ask you to be good enough to reply."

Contracts for Steel Work.—Following the explanation of the Atbara bridge contract comes the announcement in the daily press of a large Japanese steel contract placed with an American house, in fact with the contractors for the Atbara work, viz, The Pencoyd Iron Works of Philadelphia. The contract is for the supply of from 8,000 to 10,000 tons of steel for bridges within a year for the Japanese government. The value of the order is $750,000. We should think it is pretty certain that here again the time element influenced the placing of the contract, and it is interesting in this connection to draw attention to a statement made last week at the meeting of the British Westinghouse Company. The contract for the iron and steel work for the new works to be erected at Manchester is to be executed by the Carnegie Company, of Pittsburg, within four months. It seems that the present state of English iron and steel works would not allow them even to look at such urgent business.

Record Trip.—*The American Electrician* says that the longest trip of storage battery automobiles ever reported is that of Comte de Chasseloup Loubet, who drove, July 2nd, from Paris to Rouen without recharging, the distance being some 85 miles, and the time 7 hours and 15 minutes. After recharging, the return trip was made the same night in practically the same time. The vehicle was of the Jeantaud make.

Appointments Vacant.—The D. P. Battery Company wants a works' manager at the Lumford Mills, Derbyshire. See "Official Notices" this week.

The Edinburgh Corporation wants two assistant engineers for its electricity supply stations at £100 a year. See "Official Notices" this week.

A telegraph foreman is required for the Telegraph Department, Gold Coast. See "Official Notices" for particulars.

The Government of Jamaica requires an experienced electrician to act as inspecting engineer for all matters connected with electricity, at £500 per annum. See "Official Notices" this week.

Electric Motor Carriages, ad lib.—They are talking of very big things in the automobile way across the Atlantic. We read that President Rice, of the Electric Storage Battery Company, says that orders have recently been placed for 4,200 vehicles at an aggregate selling price of some $8,000,000. They consist of about 2,000 pleasure vehicles, 2,000 hansoms and broughams, and 200 delivery waggons. It is anticipated that they will not all be sold, but the greater part will be operated by the local sub-companies of the Columbia and Electric Vehicle Company. By the way, we presume that in keeping with our namesake's ruling, this company should reconstitute itself as the Columbia and Automobile Company.

The British Association.—Canterbury has appointed an influential executive committee to carry through arrangements for giving the members of the British Association and the French Academy of Sciences a fitting reception on September 21st. The visitors are expected to number about 1,500.

Apparent Dark Lightning Flashes.—Lord Kelvin writes from Aix-les-Bains, August 7th, to *Nature*:—

> Last night, during a thunderstorm of rare severity, in which brilliant flashes—single, double, triple, or quadruple—followed one another at intervals often of not more than a few seconds of time, I was surprised to see, with great vividness, on a suddenly illuminated sky, two nearly vertical lines of darkness, each of the ordinary jagged appearance of a bright flash of lightning. I remembered to have seen two real flashes of just the same shapes and relative positions, and I concluded that the black flashes were due to their residual influence on the retina. I turned my eyes quickly from the dark sky outside to an illuminated wall inside the house, and I again saw the same double dark "flash," which verified my conclusion in an interesting manner. The fatigued part of the eye failed to perceive the sudden brightness of the sky in the one case and of the wall in the other.

Swiss Visit of the Institution.—The secretary asks us to remind those who, being eligible, wish to participate in this visit, and who have not already applied for tickets, that applications should be submitted to him before *Thursday*, the 24*th inst.*

Speed Tests on High Speed Electric Railway.—The *Street Railway Journal* publishes some speed tests made upon the Cleveland-Lorain Railway, which are of interest as being made upon a high speed road that has practically no grades and few curves. The cars tested have four G.E. 57 motors geared 1 : 5·7, with 33-inch wheels and Brill trucks. The cars weigh 24 tons (apparently 2,000 lb. tons). On a grade of 1—500, the speed per hour taken at the end of six periods of 10 seconds each is given, west bound, 9·7, 26 6, 34·8, 39·6, 40·8, 47·2. By the end of 60 seconds the car had run 2,913 feet, at an average of a little over 33 miles per hour. East bound and probably up grade the speed attained was 43·1 miles per hour in a distance of 2,520 feet, but the average speed between the fortieth and fiftieth second was 47·4 miles per hour. Similar differences appear with other cars, but practically the tests show that between 40 and 50 seconds after starting, a speed of 40 miles can be easily exceeded against a wind of 10 to 15 miles' velocity. On a run of 60 seconds of a 23-ton car in which a distance of 2,802 feet was covered, the following readings will be of interest for each period of 10 seconds on a down grade of 1 in 500:—

Seconds.	Amperes.	Volts.	Feet run.	Total distance.
10	485	500	149	149
20	350	520	144	493
30	275	550	483	976
40	225	570	559	1,535
50	195	575	630	2,165
60	180	580	637	2,802

On a nearly level and straight track, with moderate wind of 6 miles per hour, the traction in both directions was 31·75 and 32·53 lbs. per ton at speeds of 40 to 49 miles per hour, and 39 to 51 miles. These are the average readings at two points on the track under favourable conditions. Other tests show tractive forces of 30·8, 34·1, and 32·6 lbs per ton, at similar speeds up to 51 miles.

Boilermakers Busy.—"Remarkable activity" is the account of the boilermaking industry during the past quarter. Mr. Knight, the general secretary of the United Society of Boilermakers and Iron and Steel Shipbuilders, reports that the demand for men has been greater than the supply. The demand fluctuates very considerably. This is practically unavoidable, but Mr. Knight adds, if it were possible to regulate the demand so as to ensure a steady and continuous employment, it would be an unqualified blessing both to employers and to workmen.

The Progress of the Manchester Electricity Works.—For the purpose of the Iron and Steel Institute visit to the Corporation electricity works this week, Mr. C. H. Wordingham, the city electrical engineer, drew up a pamphlet giving particulars of the generating and distributing plant at the central station, Dickinson Street, and the various sub-stations. The works were started in 1893 with a capacity of 1,320 KW., with plenty of floor space and chimney accommodation to allow for large extensions. Vertical compound condensing engines, 100 H.P. and 400 H.P., driving by means of link belts shunt wound continuous current bipolar dynamo machines, were installed, and the employment of jockey pulleys riding on the top slack side of the belts for greatly shortening the length of the drive is said to have been amply justified by experience, the loss of power with this method of driving compared with an ordinary belt being inappreciable. Lancashire boilers with Galloway tubes were installed, and coking mechanical stokers. The first extension was carried out in 1894-5, and consisted of two more 400-H.P. engines of the same design, with corresponding dynamos. The second extension took place in 1895-6, when the buildings had to be enlarged, and at this stage Mr. Wordingham was appointed consulting as well as resident engineer. The definite plan laid down when the original works were designed for extending plant has been strictly conformed to in subsequent developments and the same type of plant retained. Experience has shown that this course was well advised, but the uniformity has been broken by the erection of two horizontal engines of the same power as the vertical engines, driving similar dynamo machines by means of ropes instead of belts, this being done for purposes of comparison with the vertical sets, but the original design has been fully proved to be the better. The 1895-6 extension added six vertical sets, 400 H.P., and two horizontal, an extension to the boiler house, and five more Lancashire boilers. In 1897-9 the third extension was taken in hand. The large increase in size of the works had rendered the small units of plant originally put down practically useless, and the six small sets were removed for replacement by two large engines of 2,500 H.P. each for direct driving. On the space formerly occupied by generators developing 600 H.P., there are now fixed generators developing 5,000 H.P. The whole of the balancing on the five-wire system is now done by means of motor generators instead of dynamo machines. Six more Lancashire and four Babcock boilers were installed. It should be added that this last extension is not yet quite complete, the second large generator being still in course of erection. Mr. Wordingham follows with a description of the station as it now exists, also the sub-stations, mains, &c. The electric street lighting at Manchester is not a large item, there being only 28 open type arc lamps and one enclosed in use. All the lamps are fed from the ordinary distributing mains. The unenclosed arcs take 10 amperes and the enclosed 5 amperes. There were at June, 1899, 2,703 consumers with 261,988 8-C.P. lamps (or equivalent) connected (this comprising 379 motors aggregating 1,320 H.P.). The total demand, if all consuming devices were working at once, would be 8,430 KW. For the year ended March 31st, 1899, 4,773,247 units were sold, the total maximum supply demanded being 4,246 KW. The total costs per unit sold were 1·53d., the works' cost being 1·11d. Large extensions are now in progress for supplying outside districts, a scheme which has been often referred to in our columns, and for traction purposes. At a station to be erected in Bloom Street, there will be four direct coupled sets of 1,800 KW. each, to give current either for lighting at 400 to 440 volts, or for traction at 500 volts. These generators are already on order. This plant will deal with an area having a radius of about half a mile from the station. The rest of the area of supply will be dealt with by means of an entirely new generating station at Stuart Street, $2\frac{3}{4}$ miles from Dickinson Street. Here there will be fixed generators producing three-phase current at a pressure of 6,500 volts, which will be transmitted to a number of sub-stations situated at various points in the district of supply. At these sub-stations the high pressure three-phase current will be converted into low pressure continuous for all purposes, viz., lighting and traction on a three-wire network with 200 volts on lamps, 400 for motors, and traction at 500 volts.

A Method for Determining the Resistance of Electrolytes.—This new method has recently been worked out by Parker C. McIlhiney (*vide Journal of the American Chemical Society*, Vol. 20, pages 206—209), and whilst not so accurate as that of Kohlrausch, is of advantage for making many readings in a short space of time. It consists in determining by a galvanometer, preferably a D'Arsonval, the potential difference between the ends of a known resistance placed in series with the resistance to be determined. The current is supplied by a gravity battery, and before passing through the electrolyte, it is transformed into an alternating current by means of a rotary pole changer, but the current passing through the known resistance is direct. When a current passes through two resistances in series, the fall of potential in each of them is proportional to its resistance.

Chemical Effects of X Rays.—When photographic plates that have been exposed to the action of X rays are afterwards exposed to light, the image undergoes reversal in the same way as if both exposures had been made to light, and the precise character of the phenomena depends on the relative magnitudes of the exposures. Plates exposed for some time to X rays show increased sensitiveness to the less refrangible rays. An interesting communication on this subject was recently made by P. Villard in the *Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences*, Paris, Vol. 128, pages 237—239.

The Solution of Platinum and Gold in Electrolytes.—This subject was studied by Max Margueles last year, and a paper appeared by him in *Poggendorff's Annalen der Physik und Chemie*, (II.), Vol. 65, pages 629—634, in which the results of his researches were given. In his earlier experiments, it may be remembered, an electro-magnet with armature served as contact breaker to the current from two Daniell cells, and between the terminals of the coil of the magnet an electrolytic cell with gold or platinum electrodes was introduced. With this arrangement the metal can be dissolved in hydrochloric, nitric, or sulphuric acid, or in potassium or sodium hydroxide. The metals always dissolve from the electrode, which is the anode to the battery current. The solution is, however, in some way assisted by the current from the magnet, as neither a constant nor intermittent current from the battery alone is capable of effecting solution. In the same journal Margueles makes some additions to his former statements with reference to the dissolving of platinum and gold in electrolytes. The dissolution of platinum takes place only at the anode when the cation of the electrolyte is hydrogen; in salt solutions the platinum is attacked simultaneously at both anode and cathode. Platinum not only dissolves in the electrolytes previously named, but also in phosphoric, formic, and acetic acids; oxalic acid is, however, without effect.

Determination of Polarization.—In an electrolytic cell of resistance, R, with insoluble anode, through which current, C, is passing with E.M.F. = E, we have $E = p + CR$, where p is the polarization. If a thin sheet of metal be interposed between the electrodes so as to divide the cell completely, without sensibly affecting its resistance, and the current be maintained unchanged, we have $E' = 2p + CR$, or $p = E' - E$. In putting the method into practice, the main difficulty is encountered in arranging the cell so that the third electrode may be put in or taken out easily, and in such a way that the current shall pass through it, and not round it. A rectangular ebonite cell is provided with platinum electrodes fitting into grooves in the walls 60 mm. apart. Between these a third groove, 8 mm. deep and 0·25 mm. wide, receives the third electrode. This depth is sufficient to prevent undue leakage round the electrode with moderate conductivities and current densities. A greater depth would be better. About half an hour elapses before the polarization becomes constant. The following are some of the results obtained:—

Copper Sulphate, 16 per cent., at 14·7—14·95°.

Current density	0·03	0·06	0·12	0·2	0·3 amp. sq. dcm.
Polarization ...	1·591	1·628	1·668	1·695	1·717 volts.

Silver Nitrate, about Normal, at 15—15·5°

Current density	0·015	0·03	0·06	0·12	0·2	0·4 amp. sq. dcm.
Polarization ...	0·888	0·897	0·903	0·908	0·926	0·935 volt.

The above is an abstract of a paper by Karl Heim in the *Zeitschrift für Elektrochemie*, Vol. IV., page 527.

NEW COMPANIES REGISTERED.

Electric Battery Case and Fittings Syndicate, Limited (63,268).—This company registered on August 10th, with a capital of £12,000 in £1 shares, to carry on the business of manufacturers of and dealers in electric battery cases, cells and fittings of every description, and to adopt an agreement with J. H. W. Stringfellow. The first subscribers (each with one share), are:—William Morgan, 6, Great Winchester Street, E.C., accountant; John W. Savage, 10, Hafer Road, New Wandsorth, S.W., chemist; Thomas Black, 103 Grosvenor Road, Highbury, N., gentleman; William Burley, 99, Shardeloes Road, New Cross S.E., engineer; William Pickering, 6, Garway Road, Bayswater, secretary; Edmund White, 2, Denby Road, Ealing, W., chemist; and Mrs. Jane H. Braithwaite, 390, Uxbridge Road, W. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification £250; remuneration as fixed by the company.

Brazilian Street Railway Company, Limited (63,241).—This company was registered on August 5th, with a capital of £120,000 in £1 shares, to acquire the business hitherto carried on by the Brazilian Street Railway Company, Limited (incorporated in 1868) to adopt an agreement with the said old company and its liquidators, and to acquire, construct, equip, and work railways, tramways, buildings, electric traction and lighting works, &c., in Brazil. The first subscribers (each with one share) are:—J. S. B. Hawkins, Hagenhoe Park, Welwyn, banker; A. G. Kendall, 148, Leadenhall Street, E.C., merchant; W. Martineau, 3, Beaumont Villas, Hornsey Rise, N., civil engineer; F. R. Bluett, Egerton House, Beckenham, accountant; J. Wilkinson, 38, Nicholas Lane, E.C., solicitor; H. Bluett, Egerton House, Beckenham, Kent, accountant; and J. W. Walker, 2, Abercorn Terrace, Upper Holloway, N., accountant. The number of directors is not to be less than three, nor more than seven; the first are William B. Hawkins, Arthur S. Kendall, William Martineau, Samuel J. Wilde, and T. Comber; qualification, 500 shares; remuneration, £400 per annum, divisible.

Kalgoorlie Electric Power and Lighting Corporation, Limited (63,248).—This company was registered on August 8th, with a capital of £225,000 in £1 shares (200,000 preference and 25,000 deferred), to enter into an agreement, dated August 3rd, with the Kalgoorlie Power Syndicate, Limited, to acquire, own, and work any land, water rights, electrical and other works, &c., and to establish and maintain a system of generating and supplying electricity for mining purposes, and otherwise. The first subscribers (each with one share) are:—J. T. Thompson, 116, Nevill Road, Stoke Newington, N., gentleman; C. E. Mozley, 257, Winchester House, E.C., secretary; S. F. Wall, Rock Villa, Wallington, Surrey, clerk; C. N. L. Shaw, 1, Elm Villas, Derby Road, South Woodford, clerk; W. Owston, 134, Dornton Road, Balham, S.W., clerk; H. D. Kerr, 5, Buaburgh Terrace, N.W., secretary; and M. E. Williams, Winchester House, E.C., solicitor. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification, £250; remuneration, £250 each per annum (an extra £100 for the chairman), and a share in the profits.

Sun Electrical Company, Limited.—This company was registered on August 9th, with a capital of £50,000 in £1 shares (20,000 preference) to acquire and take over as going concerns any electrical businesses, and to carry on the business of manufacturers of and dealers in electrical accessories and instruments, wires, cable and lines of all kinds; electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power and otherwise; bicycle, tricycle, velocipedes and motor car manufacturers; cycle accessory and appliance manufacturers, &c. The first subscribers (each with one share) are:—F. H. Minn, 77, Grange Park Road, Leyton, electrician; F. J. Collis, 61, New Kings Road, S.W., electrician; G. Payne, 53, Goldhurst Terrace, South Hampstead, N.W., gentleman; R. T. Smith, 61, Carey Street, W.C., solicitor; N. H. Boyne, 61, Carey Street, W.C., solicitor; J. W. Beacher, 4, Queen Victoria Street, E.C., stockbroker; F. O. Smith, Hilldene, Harrow, solicitor. The number of directors is not to be less than three nor more than five; the first are F. H. Minn (managing director), R. T. Smith (chairman), and G. Payne; qualification, £200; remuneration as fixed by the company.

Woking Laundry Company, Limited.—This company was registered on August 2nd, with a capital of £2,500 in £1 shares, to acquire and carry on the business of the Woking Sanitary Electric Laundry Company, Limited. The first subscribers (each with one share) are:—C. A. Rollason, 6, Fairlight Avenue, Harlesden, N.W., engineer; G. R. Rollason, 26, Greenhill Road, Harlesden, N.W., engineer; W. G. Parker, Windlesham Road, Harlesden, N.W., gardener; E. T. Pimms, 34, High Street, Harlesden, licensed victualler; E. Mann, Palace Chambers, Westminster, S.W., engineer; W. H. Fletcher, 123, Abbey Road, N.W.; and W. F. Fearn, 3, Delahay Street, Westminster, solicitor. The number of directors is not to be less than three nor more than seven; the first are E. Mann, W. H. Fletcher, and C. A. Rollason; qualification, £50; remuneration as fixed by the company.

River Plate Construction Company, Limited (63,271).—This company was registered on August 10th, with a capital of £120,060 in 1,200 £100 ordinary shares, and 1,200 1s. deferred shares, to carry on the business of electrical engineers and suppliers of electricity for the purposes of light and power, and to establish and maintain electric lighting works, signalling, telegraphic, telephonic, and other systems, tramways, railways, &c. The first subscribers (each with 10 deferred shares) are:—C. Bright, 14, Copthall Avenue, E.C., engineer; A. F. Farish, 57½, Old Broad Street, E.C., solicitor; A. G. Lewis, 47, Park Road, Forest Hill, clerk; E. E. Ford, 12, Kylemore Road, N.W., gentleman; T. F. Stevens, 37, Sandown Road, Woodside, S.E., gentleman; G. A. Eggleton, 10, Cheriton Square, Upper Tooting, S.W., secretary; W. A. Hunter, 27, Trossacks Road, Dulwich, S.E., clerk; J. W. Ward, 14, Marney Road, S.W., gentleman; T. C. Richards, 57½, Old Broad Street, E.C., clerk; and W. S. Wild, 33, London Road, Clapton, N.E., gentleman. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification, £10; remuneration, £100 each per annum.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Thomas Parker, Limited (40,973).—This company's annual return was filed on July 20th, the entire capital of £75,000 in £10 shares being taken up; 1,750 shares are considered as fully paid and £10 has been called up on each of the remaining 5,750, resulting in the receipt of £57,500.

Oldham, Ashton and Hyde Electric Tramway Company, Limited (55,318).—This company's annual return was filed on July 28th, when the entire capital of £30,000 in 4,000 ordinary and 4,000 preference shares of £10 each was taken up and paid in full.

CITY NOTES.

Liverpool Overhead Railway Company.

The half-yearly meeting was held on Tuesday, at the Law Association Rooms, Cook Street, Liverpool, Sir Wm. Forwood, chairman of company, presiding.

The Chairman, in moving the adoption of the report, said it had been the good fortune of the directors to meet the shareholders each half-year with an account showing expanding traffics and increased passenger receipts. He therefore regretted they could not on this occasion render to them a similar gratifying statement. It was true that they showed a small increase of 2,338 in the number of passengers carried as compared with the corresponding half of last year, but this was due to the late service of trains, which, by permission of the Dock Board, they now ran to Seaforth, which had given them a traffic of over 100,000, and also to an increase of 286,486 in the number of workmen carried, owing to the extension of time they had given to working men's return tickets; but their loss of revenue on the southern section of the line, between the Pierhead and the Dingle, had been very little less than £2,000 in the half-year. This loss was due entirely to the competition of the Corporation electrical tramways, which were now carrying passengers to the Dingle, a distance of 2½ miles, for 1d. Glasgow, which had a model system of tramways, for an equal distance charged 2d. and 2½d. It was admitted by the chairman of the Tramways Committee that they made a loss last half-year of £7,000 on the entire service, and, so far as he had been able to analyse their accounts, the loss on the Dingle line had exceeded this amount. The public had an undoubted right to enjoy the lowest possible fare at which the tramways could be worked, but the City Council had no right to run their tramways at a loss, to the injury of private enterprise. It was not merely making the general community pay for the benefit of the few, but introducing a principle most disastrous to the prosperity of the country. A continuation of the present tramway policy would mean the levying of a tramway rate to pay the annual deficit, and the Overhead Railway Company, as one of the largest ratepayers in the City, would have to contribute to this rate. He knew that they would agree with him that this was scarcely a fair state of things. It was not ordinary business competition, and, if it occurred in other walks of life, Parliament would step in to stop it. Certainly the Overhead Railway was entitled to the special consideration of the City Council. It was constructed solely to facilitate and cheapen the service of their docks, and to enable Liverpool to maintain her commercial position, and it had, undoubtedly, largely contributed to this result. Liverpool owed its very existence to its commerce, and one would have thought the first care of the City Council would be to conserve the interests of an undertaking admittedly doing a great public service for the commerce of the port. On the contrary, they saw not only public money being used to their injury, but, to compete with them, a speed was maintained through the public streets frequently much in excess of the Board of Trade regulations, which would not be possible unless the police were employed to safeguard the traffic. Their railway was further threatened by a proposal of the City Council to obtain running powers over their Waterloo and Crosby tramways and by the construction of an electric tramway along the line of docks, running parallel with the overhead railway. He could not think that either of these proposals were likely to be seriously considered. To construct a line of electrical tramways along the line of docks would simply be to duplicate so much capital. It was admitted that the Overhead Railway gives an excellent service, both in speed and in the frequency and regularity of the trains, and it did that without any interference with the street traffic. He had thought it well to bring these circumstances before the shareholders, but he was sure they need not feel any alarm. He thought they were now encountering the worst of the tramway competition. Matters had been very much rushed, but he saw indications that wiser counsels would now prevail on the Tramways Committee, and that they would try to get back to a sound business basis. He could assure them that the directors of the company had pursued a watching and waiting policy. They had not attempted to meet the competition by reducing their fares. They had anticipated the difficulties of the Tramways Committee, and felt sure that when they had some experience of working with electricity, they would find out—as the Overhead Railway Company had found out—that the cost of working during the first year was not a basis upon which they could calculate in future, and that it was not possible to permanently have a penny stage of 2½ miles, except at a serious loss. Referring to the accounts, he said the gross receipts for the half-year had been £36,492, against £37,220 in the same half of last year, or a decrease of £728. The expenditure had been £24,924, as against £23,326, showing an increase of £1,548. This increase had been accounted for in a larger payment for coal of £691, owing to the flooding of the mine with which they held their contract. The expenditure in materials had increased by £257, principally due to the renewal of their commutators, and the increased price of copper. Then during the past two years they had spent £2,300 in the removal of their storage batteries. They had also during the half-year to re-wind a great many of their motors; but the result of all this extra outlay, he hoped, would enable them to work more economically during the present half-year. It had always been their policy to maintain the line in a thoroughly efficient condition, and in the speed, comfort, and punctuality of their service to maintain the good opinion they had earned. Their earnings per passenger had fallen from 1·98 to 1·95, owing to the decrease of first-class traffic from the Dingle and the increase of workmen's return tickets. Of the future he would not prophesy, but he thought they had seen the worst of the tramway competition. Municipal trading was a dangerous and uncertain factor, and had not been a success in this country. The directors would carefully watch developments, and the shareholders might depend that their interests would be carefully safeguarded in every way. He was pleased to add that the line had lost none of its attractiveness to the holiday people, as the traffic last Bank Holiday was the largest on record.

Mr. R. Hobson seconded, and the motion was carried.

It was further resolved that a dividend at the rate of 5 per cent. per annum be paid on the preference shares for the half-year, and a dividend at the rate of 2½ per cent. per annum be paid on the ordinary shares, leaving a balance of £4,320 to be carried forward.

The Chairman, in acknowledging a vote of thanks to the directors, said it was very gratifying to receive such a vote, seeing the shareholders had got a reduced dividend. This showed that their efforts were appreciated. He still looked forward with confidence to the future prosperity of the Overhead Railway Company.

Waterloo and City Railway Company.

Mr. Wyndham S. Portal (chairman) presided on Thursday last week over the half-yearly meeting of the above company, and in moving the adoption of the report said the figures had been fully explained in previous half-years, and did not require on this occasion any detailed examination. On the last occasion he congratulated them on the completion and opening of the line, and now he had to congratulate them on the first complete half-year. Capital account showed total expenditure to the present time of £566,134, of which £16,678 had been expended during the past half-year. It was estimated that a farther sum of £56,000 would be required, which was amply provided for by the company's available powers amounting to £145,531. The authorised capital is £720,000, and of that, £540,000 had been raised by the issue of ordinary stock, and £26,000 by debenture stock, making a total amount raised of £566,000, or an increase of £5,000 since the preceding half-year ending December, 1898. As regarded the revenue account, during the past half-year the gross receipts, after deducting Government duty, had amounted to £13,114. £13,093 was received in fares and £300 in rents. Government duty was £278, leaving the sum of £13,114, from which the South-Western Railway Company had retained for working expenses, £4,690, or, £1,950 less than the actual working expenses. The balance was £8,424, which was payable by the South-Western Railway Company, under the agreement of March, 1894, to enable the Waterloo and City Company to pay a dividend at the rate of 3 per cent. per annum on the ordinary and borrowed capital. To this £8,424 they had to add £10 10s. for transfer fees, which made £8,434 odd, and they had to deduct £406 for general charges, and £5 18s. for law and Parliamentary expenses, which left £8,021 to be carried to the next account. The net revenue account commenced with £290 balance brought forward from last half-year, then they had the figure of £8,021 just mentioned, to which they added £190 for bankers and general interest and an item of £625 10s. described as "rent charge," and this made a total on the credit side of that account of £9,155. Out of that they had had to provide £324 as interest on debenture stock, and £458 rent charge payable to the South-Western Railway Company, in respect of the easement at Waterloo Station and that left them with £8,372 available for dividend, and they proposed to pay a dividend at the rate of 3 per cent. per annum on the ordinary capital, and carry over £272 to the next half-year. They would notice the auditor had added at the end, the words, "There is a contingent liability to repay to the South-Western Railway Company, the deficiency in respect of net revenue." This referred to £1,950 which he had mentioned, and to a sum of £1,869 which was similarly provided by the South-Western Company in respect to the working of the preceding half-year. These two amounts together made £3,819, and the agreement of March, 1894, provided that if in any subsequent half-years the difference between receipts and working expenses was sufficient to pay a dividend of more than 3 per cent. the South-Western Company should be at liberty to recoup themselves the amounts which they had provided in previous half-years. This was the contingent liability to which the auditors referred. The number of passengers carried during the past half-year was 1,715,825, or a daily average of 11,142, and the number of season ticket holders at June 30th last was 747, which was estimated to be equal to 194,220 single journeys, or a daily average of 1,261. This made the total daily average number of journeys 12,403. As the railway was only in its infancy they were unable to make a comparison with any previous period, and they would, of course, remember that the City station was still unfinished, inasmuch as the subways and approaches to be constructed by the Central London Railway Company had not yet been completed. Two days ago he received a report of the engineers, Mr. Galbraith and Prof. Kennedy, which he thought they would like him to read, as follows:—"The works of the railway have now been tested with 12 months' continuous running and are all in good order and repair. A little trouble was at one time experienced from leakage of water in the short brick tunnel at Waterloo, but it has much diminished, and the pumps which were provided to meet this contingency were found to be amply sufficient. The iron tunnels within which the railway and City station were constructed are quite watertight and are perfectly sound. The Central London Company's subways at the Mansion House are fast approaching completion, and it is hoped that three additional communications between the streets and the subways will be ready for use in October, namely, (*a*) in Mansion House Place, (*b*) at the Union Bank, Princes Street, and (*c*) at the junction of Lombard Street with the Poultry. At the same time the two staircases at the City station will be shortened and improved. Since the opening of the railway the line has been continually worked with the electrical plant provided in the generating station at Waterloo. The electrical difficulties which occurred in the

Digitized by Google

earlier working of the line have, as was to be expected, yielded to time and experience, and all the electrical apparatus appears now to work regularly, steadily, and without difficulty. The trains have for months past been running to a time table at six minutes interval during the busiest part of the day. Further rolling stock has been ordered by the London and South-Western Company, and when this arrives it is intended that the trains shall be still more frequent than they are at present."

Lieut.-Col. the Hon. H. W. Campbell seconded the motion and it was carried.

National Telephone Company.

Mr. J. S. Forbes (chairman) presided on Thursday last week over the twenty-fourth ordinary general meeting of the shareholders of the National Telephone Company held at the Cannon Street Hotel, and in moving the adoption of the report said the accounts were very similar to those of previous years, the only essential alteration being in the figures. Under all the circumstances, the directors considered the figures eminently satisfactory. There had been an increase in the income for the half-year of £63,000, which had been attended with an increase in the working expenses, but still they were left with an increased profit of £24,844, which was no inconsiderable sum. Comparing the figures with the corresponding half of 1898, they would see that the Post Office royalties had increased by a very large sum, and amounted to £58,859—an increase of £9,186. The net income had increased by £54,000, and the working expenses by £29,000. The working expenses had been reduced from 61·94 per cent. to 61·15 per cent., which was a tangible gain. The debenture and other interest had increased by £7,623, but the preference and ordinary dividends were practically the same. They proposed to carry to reserve £60,000 as against £50,000, and to carry forward £5,213 against £548. A most interesting and satisfactory feature was the large sum for rentals carried forward for unexpired terms. They had already received the enormous sum of £651,000 in respect of services to be rendered by the company after the expiration of the term they were dealing with, and that was an increase of £56,000. In fact, so far as the year had gone, it had been a record one, and they had had the largest accession of subscribers they had ever had in any year of the company's existence. Out of the available balance of £178,963, a dividend of 6 per cent. on the ordinary share capital was recommended. With respect to the capital expenditure that must always go on, for they could not expand the business without money, and if they were to go on in the same ratio as they had last half-year—an addition of 17,000 subscribers—they must have more money to meet the large expenditure involved. In the half-year under review, £372,000 had been expended on capital account in the erection of 10,479 additional exchange and private lines, and in the construction of underground lines. Their system was undergoing a gradual change; the vital feature being that they were getting under the earth, and a very large sum of money had been spent in the last few years in placing the wires underground in Liverpool, Manchester, Birmingham, Bradford and many other places. They estimated that at the present moment they had about £750,000 lying in the earth, but, of course, in laying out a new system they allowed for an expanding business. There it was, however, lying ready to be utilised as the wants of the community increased. Of course, interest had to be paid on that money, but still the shareholders had a fair dividend, and were in possession of a latent power which would enable them, at a comparatively small cost, to greatly increase the number of subscribers, so that the cost, which was harped upon by critics as having been extravagant and watered, in due course of time would come down very nearly to the moderate figure which the enthusiastic promoters of new schemes believed to be the approximate one. That, however, could only be in a great undertaking, and not in a small one.

Lord Harris seconded the motion, and it was carried unanimously without discussion.

The meeting was then made special, and the Chairman moved a resolution giving power to increase the capital of the company by £2,000,000 by the creation of 400,000 new ordinary shares of £5 each. He said that might be considered to be a tall order, but still, they had to look things in the face, and that great corporation could only be made efficient by expansion, and expansion meant money. If they went on spending at the rate of £600,000 or £700,000 a year they could not go far without getting into debt, and they must either have behind them the power to meet the debt or stop. He thought their company was likely to go on, and it was time that they had to face a new Government policy, but if they could not get all they wanted they must get all they could. They were, after all, only the licencees of the State and they had now come to an agreement with the Government because they thought it was politic in the interests of the shareholders. They had got to face the competition of the Post Office, but yet they had been so fairly treated in the course of recent discussions with the Government that they were bound to act loyally in assisting them in the object they had in view. How far it would succeed time only would show, but the company must not be behindhand in securing their own position and also in expanding, and honestly and in good faith see what they could do to make the position of the Government that which they wanted. The Government wanted to popularise the telephone, and the company would do its best to help that policy forward. In moving the resolution, he would warn nervous people that it did not mean they were coming forward at once for £2,000,000, but they believed that it would be wise to be armed with the power to raise the money.

The resolution was seconded by Lord Harris and carried.

British Electric Transformer Manufacturing Company, Limited.

The *Times* contains a report of the first ordinary meeting of this company held at Faraday House, Charing Cross Road, Mr. R. Stewart Bain presiding.

In moving the adoption of the report, the Chairman stated that prior to the completion of the company's works in October last, the manufacture of their transformers had to be carried on in a temporary workshop, which was found to be both inconvenient and expensive. The shareholders might take it that the first three months of the period under review were not profit-earning, although the time was usefully employed in bringing the transformers prominently under the notice of future customers and in organizing the staff On the whole, he thought that they had every reason to be satisfied with the results achieved during the nine months that they had been working in their own factory. Turning to the profit and loss account, he pointed out that the total sales, after deducting returns, amounted to £10,991. Of this sum, £5,633, or over 50 per cent, represented the sales of the three months ended June 30th last, thus showing that as their organization became perfected their capacity of output increased more than three-fold. He regarded this as a very encouraging feature in relation to the future of the company. The item of £1,623 represented the value of the work in progress at the close of the financial year. It was only taken at cost, and would, of course, show its due proportion of profit when completed. The remaining items brought up the total amount on the credit side of the profit and loss account to £12,835. On the debit side they had the aggregate manufacturing costs figuring at £10,230. This was more than it would have been but for their having to occupy temporary workshops from June, 1898, to the following October. Against this, however, must be placed the fact that the prices of copper, iron, and other materials had increased during the past six months. The general charges, £942, could not, he thought, be considered extravagant. His own feeling was that if it were desired to make a business pay they must commence by studying the strictest economy during its early years. As proof that the directors practised what they preached, he might state that, of the fees due to them, £669, they had relinquished £369. The amount drawn about recouped them for their out-of-pocket expenses in attending to the company's affairs. Out of the balance available for distribution the board recommended the payment of a dividend of 6 per cent. on the subscribed capital, leaving £237 to be carried forward. To the sum of £25,000 the cost of patents as per agreements of March and May, 1898, there had to be added £250, being the expenditure during the year in obtaining additional foreign patents. The company's transformers were covered by letters patent in France, Belgium, Italy, Austria, Switzerland, the United States, New South Wales, South Australia, West Australia, Queensland and Tasmania, and an application had been made, and was now under consideration, in regard to Germany. The question of how these foreign patents should be dealt with was a matter which was occupying the attention of the board. The directors attached considerable value to them, but whether they would be sold or worked by this company was a subject for future decision. Already the board had been approached with a view to the sale of some of them. Referring to the company's prospects, he said that, at the date of the report, they had orders on hand amounting to £9,260, which was nearly equal to the sales of the period under review, and additional orders had come in since. Their working capital was very small, and they had to deal with the fact that one of the conditions of municipal contracts was, that from 10 to 20 per cent. of the amounts represented by such contracts was retained for a year. The board had, therefore, resolved to issue a further 5,000 shares, which would be offered at par, to the subscribers for the original capital. He could not afford the shareholders better proof of the directors' confidence in the business than by stating that it was their intention, as well as that of the officials, to put more of their own money into the company.

Mr. Reginald J. Wallis-Jones having seconded the motion, it was unanimously agreed to.

W. T. Henley's Telegraph Works Company.

On Tuesday at Cannon Street Hotel, Mr. Sydney Gedge, M.P., presiding, the resolutions passed at the extraordinary meeting held on July 31st were unanimously confirmed. At a subsequent meeting of preference shareholders a resolution was passed ratifying the agreement of July 19th between George Sutton on behalf of the holders of the preference shares of the company of the first part, Arthur Edward Salmon on behalf of the holders of the ordinary shares of the company of the second part, and the company of the third part, and declaring the same to be binding on all the holders of the preference shares of the company. And at a third meeting of the ordinary shareholders the agreement was also ratified.

The Hampstead Electric Supply Company.

A meeting of this company was held last Friday at Winchester House, the Chevalier Soares presiding. The object of the meeting was to pass certain resolutions altering the articles of association, as the company had applied to the Stock Exchange Committee for a settlement, and they, in compliance with their regulations, wanted the various alterations made. The chairman moved the adoption of the resolutions, Mr. Watling seconding, and they were carried. A confirmatory meeting will be held in due course.

British Electric Works Company, Limited.

The first general or statutory meeting of the shareholders in this company, of Birmingham, was held, on 14th inst., at the Law Association Rooms, Cook Street, Liverpool.

Mr. W. M. Brigg, in addressing the shareholders, said that the meeting was a formal one. He thought they might congratulate themselves on the fact that the whole of the capital had been subscribed, and that they had come into possession of exceptionally good works—works that were designed and intended for the cycle trade, but which lent themselves very well indeed to the business the company had in view in taking them over, which was largely the manufacture of electrical fittings. The articles they produced were meeting with a very ready and very acceptable sale. They had been introduced to and were being taken up by the Government, the Post Office, and the Naval Department, and the company's name was on their list. Since the middle of May, when the company actually came into possession of the property, they had had a good deal of machinery to alter and to adapt to the particular purposes required, and they were now really beginning to reap a benefit. They had a good many orders on hand and a good many more in prospect. He hoped that the business would go on as it had begun, and increase and develop, and that at the end of the financial year they would have a dividend to declare.

Hong Kong Electric Company, Limited.

The tenth ordinary yearly meeting was held at the offices at Queen's Buildings.

Mr. H. L. Dalrymple (the chairman) congratulated the shareholders on the further increase in the company's business, the gross earnings showing an increase of upwards of $21,000. The increase had spread almost equally over all branches of the company's business, with the exception of arc lighting, which has remained stationary. During the 12 months under review they carried out a large number of installations, and at the present moment have a considerable amount of installation and other work in hand, all of which will increase the demand for lighting. The board still continue the policy of installing the light at as near cost as possible. The chairman proposed that the report and accounts as presented be adopted, that a dividend of 6 per cent. (60 cents per share), absorbing $18,000, be declared, and that $17,354.23 be written off plant account for depreciation.

Mr. Veitch seconded, and the motion was carried.

Blackpool and Fleetwood Tramroad.—At the half-yearly meeting of this company, held on 15th inst., Mr. G. Richardson, the chairman, said that they had conveyed 620,000 passengers during the past six months. The total receipts during that period amounted to £9,991. From July 1st to August 12th the receipts were £7,981, and they had carried only one-third less passengers during that time than during the whole preceding half-year. An interim dividend of 6 per cent. was declared, and £390 carried forward.

Stock Exchange Notices.—Applications have been made to the Stock Exchange Committee (1) to appoint a special settling day in and to grant a quotation to Giffre Electro-Chemical and Power Company, Limited—110,000 £1 shares, fully paid, and to allow the following securities to be quoted in the Official List:—Imperial Tramways Company, Limited—10,000 6 per cent. cumulative preference shares of £10 each, fully paid, Nos. 1 to 10,000, 20,000 ordinary shares of £10 each, fully paid, Nos. 1 to 20,000, and £200,000 4½ per cent. first mortgage debenture stock.

The Hove Electric Lighting Company, Limited.—The directors have declared an interim dividend at the rate of 6 per cent. per annum for the half-year ended June 30th last; the dividend will be paid on October 15th next.

TRAFFIC RECEIPTS.

The Blackpool and Fleetwood Tramroad Company.—The receipts for the week ending August 12th, 1899, were £2,167 18s. 5d.; receipts for week ending August 12th, 1898, £1,923 8s. 4d.; aggregate for half-year to date, £7,981 4s. 0d.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending August 11th, 1899, were £4,489 1s. 5d.; corresponding period 1898, £2,869 19s. 7d.; increase, £1,619 1s. 10d.

The City and South London Railway Company.—The receipts for the week ending August 13th, 1899, were £1,038; week ending August 14th, 1898, £928; increase, £110. Total receipts for half-year, 1899, £6,666; total receipts corresponding period, 1898, £6,784, decrease, £118. Miles open, 8½.

The Dover Corporation Electric Tramways.—The receipts for the week ending August 12th, 1899, were £334 5s. 3d.; week ending August 13th, 1898, £259 13s. 7d.; increase, £74 2s. 8d. Total receipts to date, 1899, £5,819 10s. 10d.; corresponding period, 1898, £4,706 12s. 4d.; increase, £1,112 18s. 6d. Miles of track open, 1899, 8; 1898, 8. Car miles run, 1899, 4,667; 1898, 3,845. Number of cars, 1899, 12; 1898, 10.

The Dublin United Tramways Company.—The receipts for the week ending Friday, August 11th, 1899, were as follows:—D. U. T. Co., horse cars, £2,274 8s. 7d.; ditto, electric cars, £1,353 9s. 5d.; D. S. D. Co., electric cars, £1 284 5s. 8d.; total, £4,911 18s. 8d.; corresponding week last year—D. U. T. Co., horse cars, £2 608 3s. 0d.; ditto, electric cars, £529 11s. 11d.; D. S. D. Co., electric cars, £1,036 17s. 6d. total, £4,174 12s 5d.; increase, £737 6s. 8d. Aggregate to date, £27,670 17s. 10d.; aggregate to date last year, £26,920 9s. 5d.; increase to date, £750 8s. 5d. Worked:—The mileage open is 18 miles electrically, 26 miles by horses, as against 12 miles electrically, and 30 miles by horses, for the corresponding period last year.

The Liverpool Overhead Railway Company.—The receipts for the week ending August 13th, 1899, amounted to £2,704; corresponding week last year £1,743; increase, £331.

The South Staffordshire Tramways Company.—The receipts for week ending August 11th, 1899, were £987 2s. 6d.; aggregate receipts for 32 weeks, £30,954 10s. 11d.; week ending August 12th, 1898, £580 16s. 3d.; aggregate receipts for 32 weeks, £19,858 8s. 2d.

STOCKS AND SHARES.

Wednesday Evening.

A pleasant little rise has at length come to infuse some cheerfulness into the electric lighting market, and, although prices in the list do not show much appreciable change, the quotations are nearly all "harder." There are now to be found buyers at the middle prices instead of sellers, and with the brighter tone prevailing, the buying element came to the front with boldness. City of Londons present almost the only dull feature in the coterie, and the hopes of shareholders appear to be fast vanishing the nearer the quotation approaches its par value. A time of great stress seems to lie before the company in the immediate future, and although it will probably weather this storm as gallantly as it has passed through others, it is certainly a difficult position for the company at present.

On the other hand, Charing Cross have risen, and it is thought that the directors will have very little difficulty in raising the new capital that will be required before the company can supply current in the City. It is believed that at least 1½ million sterling will be required before effective competition can be commenced.

London Electric Supply Preference have been bought, and there has been some demand for the Preference shares of the House-to-House Electric Supply. South London Electricity have shed a small fraction, sellers predominating in the market.

The electric railway market has also been firm, the feature being a rise in Waterloo and City Ordinary. This was due chiefly to the optimistic tone of Mr. Portal at the meeting last week, whose speech was very favourably received in the Stock Exchange. Considering that the company is only in its infancy, as the chairman remarked, its progress appears to be distinctly encouraging to the stockholders. We adhere to our opinion, however, that the latter are not likely to get more than their guaranteed 3 per cent. for some few years to come. Of course, the company has the inestimable advantage of being backed by the London and South-Western Railway, without whose aid a different story would probably have been told, and the price of the Ordinary stock might have stood nearer that of the pioneer electric railway, the City and South London. The "City" Company would, in all likelihood, do much better business did it adopt a more generous scale of fares, that in force at present tending rather to foster irritation among passengers than to attract them. Central London shares present an unchanged front; the partly-paid capital is to be called up in a day or two.

Tramways Union shares are 8½—⅝, but very few change hands, as shareholders are looking forward to obtaining a better price should the company be able to go into voluntary liquidation after the sale of the last, *i.e.*, the electrical part of its lines.

Telegraph issues have fallen into a state of holiday quiescence, and scarcely a rise or fall marks the calm stillness of the share list. It has been finally decided that the Telegraph Construction and Maintenance Company should have the manufacture and laying of the new German trans-Atlantic cable to New York. It is a remarkable fact that there should be no German company able to undertake such a contract, but the foundation stone of competition has already been laid in Germany, and the provincial markets are shy of raising the price of Telegraph Construction shares, which already stand at a very substantial premium. Electric Construction 4 per cent. First Debenture were inquired for by a small buyer, with the result that the price has been raised a point.

Aluminium "A" shares continue dull, and the excellent report lately issued has had no effect in stimulating an upward move. The Hampstead Electric Supply Company has at last awakened to the necessity for obtaining a quotation of some sort in the Official List, and is taking the necessary steps in that direction. The price at present is purely nominal.

National Telephones are steady, but the observations of Mr. J. S. Forbes at the meeting produced no effect upon the price. The company is undoubtedly doing a splendid business, and there seems some justification for the opinion in the Stock Exchange that the price of the shares will touch 6 again before long. There is nothing doing in other telephonic ventures.

A prospectus has reached us, marked "Strictly Private and Confidential" of the United Kingdom Tramway Light Railway and Electrical Syndicate, Limited. The Syndicate starts with a modest capital of £20,000, and its scope lies in acting as a parental company to new electrical railway undertakings, and the like. Various concessions have already been obtained in different parts of England, the most important being in North-east Durham. The Syndicate appears to possess some chance of success, but its shares are at present, we understand, all held privately

THE MUNICIPAL ELECTRICAL ASSOCIATION.

Discussion on Mr. Edgcome's Paper* on "The Arrangement of Steam and other Pipes, and Their Fittings."

Mr. Ferranti pointed out that there was a great similarity in electricity stations between the system of steam pipes and the switchboard system of communication. With the switchboard, most engineers wished to be able to do everything, and very many complications resulted from its having to fulfil so many requirements. Very much the same thing applied to the system of steam pipes and valves. It was desired to feed every engine from every boiler in every conceivable way. For his part, he would reduce the pipes down to the lowest possible limit. He would give up many conveniences, and would do away with a great deal, provided he could bring the pipes down to an irreducible minimum. They cost a great deal to instal, and a great deal more to maintain. The stand-by losses were, to a great extent, due to pipes, and what was not attributable to pipes was, in a great measure, attributable to valves. In his opinion, the only things worse than steam pipes were valves. For his part, he would rather follow the system of putting the plant into sections than have any complicated system of steam pipes. He would rather see engines with a certain number of boilers sufficient to run and to spare attached to each engine, so that each set formed a complete unit. All that would be necessary in that case would be to have small inter-connecting pipes between the various systems available in case of a breakdown.

Mr. Gibbings (Bradford) said that with reference to the author's description on page 5 of his paper, he had found since his station was first started—practically two years—he had not had to make more than one joint. When the joint had to be made they had the advantage of being able to take out a complete packing ring instead of having to cut a special ring of asbestos or other packing. Instead of connecting the drainage pipes direct from the steam pipes, they had interposed another—a small casting. There was an overflow arrangement in the inside of this circular casting. If the steam trap was not acting properly, it was always easy for the engineer, as he went round, to see that the water was standing at a higher level than it should, that was to say, than the overflow of the water itself.

Mr. Steinitz (West Ham) agreed with Mr. Ferranti as to the complications. He should prefer one single main with a certain factor of safety. The ring main was the invention of the electrical engineer. They did not hear of it in waterworks or such like establishments. They ran more risk by the addition of the ring main than the advantages justified. Where they were using large valves they could make them act as separators by turning them upside down. It was necessary the steam traps should be regularly examined.

Mr. Boot (Tunbridge Wells) said Mr. Ferranti had referred to complicated systems of pipes. They had a steam ring, and they found it of very little use, except to give employment to fitters. They had tried almost every kind of joint mentioned by Mr. Edgcome, and had had trouble with them all. With regard to the question of covering, when they started it was not the practice to cover their valves and their fittings beyond just the ordinary piping, but they found there was a considerable loss occasioned by their not being covered, and about a year and a half ago they decided to cover every valve. The result in economy had certainly been remarkable. It seemed only a small matter, but it was extraordinary to notice the difference in temperature that it had caused in both the engine room and boiler house, so that the losses must have been considerable from these causes alone. The latest form of covering they had tried was blue asbestos, and he thought that would be satisfactory. Mr. Gibbings had mentioned the question of the reservoir. They some time ago had traps in all their drains, but they gave it up, and did away with traps altogether, bringing all the drain pipes to one large steam reservoir with the arrangement mentioned by Mr. Gibbings. They put in one blow-down pipe and the result had been satisfactory.

Mr. Chamen (Glasgow) said he was glad attention had been called to the question of steam rings, and he reminded the meeting of the terrible affair which happened at Kensington Court in the early days. He agreed entirely in this matter with Mr. Ferranti, who, he thought, had put the whole case most clearly, and the arrangement he had described was practically what he had decided to introduce in Glasgow. He had a 15-inch steam main which he had put at the highest point inside the boiler house, the connection from the boiler running up to that. That main was broken at intervals, and he had an arrangement to connect the various parts by small pipes. The only place where he thought it desirable to have a steam trap was the engine separator. Reference had been made to the question of recessed pipes. While of service in keeping the joints in sound condition, it had presented difficulties in case of repair, and he preferred the arrangement suggested by Mr. Edgcome. With regard to explosion valves mentioned on page 8 of the paper, Mr. Edgcome did not mention the double-acting valve which was in use on the Babcock boiler. As to blow-off valves, he did not think they ought in future to have the boilers' blow-off valves discharging into a common pipe, particularly in large stations. There might be a leakage to be dealt with, and there would be difficulty in finding out exactly where it was. His idea was that each blow-off valve should discharge into a separate culvert, and that in each case there should be ample facility for inspection. The engineer would, of course, take care that there were periodical examinations. In his remarks he had let the valve makers alone. Their consciences would tell them what to suggest.

Mr. Mountain (Huddersfield) thanked Mr. Ferranti for trying to standardise their steam pipes in the way he had done, although it was an expensive item. There could be no doubt they were forced to have some system of duplicate pipes. Describing the system he had adopted for draining the pipes, he said he did not have any steam traps at all; he simply drained his water to a cast-iron cylindrical vessel, whence it was taken up to a condensing tube in the roof and then conveyed directly back to the boiler. Really it was nothing more than the American system of returning condensed water, but it worked well, and they could be absolutely sure the pipes contained no water. As to the covering of the exhaust pipes, he had trouble with the heat in his engine room, and he put a casing round the pipe and let his feed water go through it. That accomplished the double process of cooling his engine room and heating his feed water. He thought if that plan were adopted it would help to economise.

Mr. Hopkinson said he was afraid the poor valve makers had a lot to answer for. It was not, however, altogether the construction of the valves, but the way in which they were used. In order to ensure their being fairly tight, valves should be closed regularly, say, two or three times a week. They were often spoilt in the first two or three days of working. If the gentlemen present could arrange some means of having their pipes cleaned before erection the trouble from valves would be largely reduced. Mr. Chamen had referred to an explosion valve, but that was not exactly the valve referred to by Mr. Edgcome. His was an isolating valve, which automatically cut off the boiler, not in the event of a large escape of steam, but immediately the pressure fell.

Mr. Ruthven Murray remarked that this was a subject of very great interest to them all, because they all had steam pipes—they even found them in water-power stations. He thought insufficient attention was, as a rule, given to providing for the expansion of pipes. They had also to provide for draining the pipes, though he dared say, by the use of superheated steam, the necessity for drainage was less than it formerly was. As regarded the means of providing for expansion, there were practically two; one was by the elasticity of the pipes, in which case they must use bends, and it was advisable to keep the pipes comparatively small in size. He thought on large steam mains Mr. Wordingham had done this by putting a series of small pipes parallel, which ought to get over the difficulty very nicely. The second way was by mechanical expansion joints, which some of them had not found satisfactory. There was a great deal of danger in the use of copper. In the matter of the blow-off valves, his practice had always been to fit on the blow-offs a valve, then a cock in series. He thought the danger Mr. Edgcome had referred to of getting steam back into a boiler might be easily and satisfactorily overcome by putting a back pressure valve on the blow-off.

Mr. Fletcher (Ashton-under-Lyne) confessed that he had listened with very great interest to the paper given by Mr. Edgcome, but he would like to point out that the valve makers were not always at fault; the blame often rested with the electrical engineers. References had already been made to foreign matter coming into the valves. He had frequently experienced that, and sometimes he had found a great part of the building inside. The by-pass was an important matter in all these things. Standardising would, he thought, save a good deal of trouble.

Mr. Wordingham (Manchester) thought the question of steam pipes was, perhaps, one of the most difficult in a central station, and it certainly was one of the most fruitful sources of worry. Mr. Ferranti's remarks referred chiefly, he thought, to large stations. He thought, however, that whether the station was large or small, it was wrong to let it depend upon a single joint in a steam pipe. They must have some means of getting around that joint, either by a ring main or a complete set of duplicate mains, and, to his mind, the latter plan offered special advantages. Seeing that they had two connections from each boiler and engine, one to each steam pipe, it followed that if they had leaky valves they were sometimes difficult to trace. It was important that there should be facilities for easily testing where the leakage was. Now in a large station the difficulties of steam pipes were enormously accentuated, because although they were growing larger units every day in their generating stations, it was very difficult to get a larger unit in boiler power. In the last station he was designing they would probably have 11 units for the generators and something like 120 units for the boilers. He did not think they wanted to carry the duplication of the steam pipes right away to every boiler. He had adopted a unit of seven or eight boilers, and there would be a duplication in the engine room, but in a sense it would not be a complete duplicate. He thought something on those lines was what was really wanted. He agreed with Mr. Ferranti that they did not want a lot of complication, but he did not agree with him if he meant that they ought only to have a single pipe on which to depend. He understood Mr. Ferranti to suggest that there should be a reserve of sections, and if so he thought there was a good deal to be said for it.

Mr. Ferranti: That is right.

Mr. Wordingham quite agreed that they only needed small interconnections. He was glad to have heard a little bit about Mr. Mountain's gravity return system, and would like to hear more. In Mr. Edgcome's paper he showed some cross-connections in his steam ring. He (Mr. Wordingham) thought that if carried out in the way suggested there would be a great amount of trouble with the expansion of the two legs of rings. One of the most important things was the question of expansion joints. He did not think there was any joint so called that was of any use, and he had had to fall back upon bent steam pipes. Mr. Edgcome apparently advocated automatic valves. To his mind, the fewer automatic things they could have about an engine house the better. As to the high steam and low water valve that they found on the Lancashire boiler, he thought it absolutely useless. As to pipe covering, he did not think accessibility to the pipes themselves was necessary, but they must have access to the joints, and therefore to that extent it must be a removable covering. If they desired a nice little engine room, it was necessary to cover the cold water pipes, otherwise the condensation of water on those pipes would cause a deal of rust.

Mr. Snell believed the best type of steam joint was the corrugated

* Electrical Review, August 11th, 1899, page 251.

Digitized by Google

ring. With regard to drainage, he did not like the idea of turning his valves upside down.

Mr. Ram suggested that if possible many boiler coverings actually helped to keep the pipes cool rather than warm.

Mr. Andrews (Hastings) wished to say a word in support of the steam ring. About six years ago they put in a steam ring at Hastings, and for four years they never had occasion to use it, and he began to look upon it as an unnecessary complication. They then had occasion to extend the ring to couple up a new boiler, and during that time a joint blew, and they had their lights out in the town for about half an hour. They must have duplicate feeders. It was absolutely necessary to provide against a fault in any part of their system cutting off the whole supply.

The Chairman, Mr. J. H. Rider, said he would like to add a few words before Mr. Edgcome replied. In the first place, he totally disagreed with the author in his advocacy of the steam ring. He thought it was time the steam ring was killed, and he thought the ring Mr. Edgcome had designed in his drawing was bad, even for a steam ring, because instead of taking his steam branches from the same side of the ring to which the boilers were connected, he took them from the opposite side. He thought he should take them from the same side, and use his ring entirely in the boiler house with the lower half having no branches at all, so that the lower part could be used as a drain. He agreed with what Mr. Ferranti had said. Supposing they had half a dozen boilers in a station, they could get all possible necessary combinations by coupling these boilers directly to their engines and by putting in a small connecting pipe. The extra advantages they were supposed to get from the steam ring and the inter-connecting devices were more than upset by the trouble of condensation and the trouble of getting water into the pipes if they were kept off except in cases of emergency. He hoped the meeting would condemn the steam ring, and let it go forth that it did not like it. He was sorry that the gentlemen who claimed to have discovered such good steam traps would not tell them where they came from, because they were things which they all desired. He thought one of the advantages of the Association should be to give information of that kind. He quite agreed with the jointing arrangement suggested, viz., corrugated brass rings. As to valves turned upside down and the liability to leakage through the glands, he knew a station where the valves were turned upside down, and he did not think a cupful of water had come out of those valves during the last two years. As to pipe covering, he certainly thought that covering for the flanges was quite as necessary as the covering for the pipes. In most stations there was a large area of joints open to the atmosphere which ought to be covered, but it was, of course, necessary that the covering should be removable in order that they might get at the joints when necessary. They were indebted to Mr. Edgcome for the able manner in which he had brought the subject forward, and he was sure they would give him their hearty thanks.

Mr. Edgcome, in his reply, said that when he got back he should start pulling down his present steam ring and arrange a station on the Gay-Rider system. With reference to the remarks of Mr. Steinitz, he thought they were answered by the fact that until the electrical engineers took the question in hand no other engineers took the trouble to give a duplicate supply of steam pipe—due to the fact that until the electric supply stations were running there was no necessity for absolute continuity of running. With gas and water works there was always a large amount of storage. With other works it caused inconvenience, but it did not advertise itself in the same way as with electric light plant. When something went wrong at other works no one knew anything about it. Various hints had been given in the course of the discussion as to special information which some of the members possessed, and he hoped at the close of the session when the reporters were not present they would tell their colleagues these good things.

PROF. KENNEDY'S REPORT TO THE LONDON COUNTY COUNCIL ON MECHANICAL TRACTION ON TRAMWAYS.

Report by Alex. B. W. Kennedy, F.R.S., &c., to the Highways Committee of the London County Council.

17, Victoria Street,
Westminster, S.W.,
June 5th, 1899.

To the Clerk of the London County Council,
Spring Gardens, S.W.

Mechanical Traction on Tramways.

Sir,

In your letter of March 3rd last you communicated to me the following resolution of the Highways Committee of the London County Council:—

"That, taking into account all of the varying circumstances, present and prospective, of tramways in London, Mr. A. B. W. Kennedy, F.R.S., do report to the Highways Committee his opinion (*a*) as to the best system or systems of mechanical traction, other than steam or cable, for adoption, on the tramways, (*b*) where, or under what conditions, an experimental line could best be introduced to initiate such system or systems, and (*c*) generally on the whole subject."

I have now pleasure in making my report to your committee, in accordance with this resolution, upon the matters referred to me.

I should like to say, in commencing, that in view of the enormous importance of this matter to London and the very great complexity of the problem as applied to London, and in view also of the very rapid extension in the use of mechanical traction which has taken place during the last few years on the Continent and in America, I have thought it desirable, before reporting to you, to make special visits to those cities both in Europe and in America in which there now exist traction systems having special interest, or containing features which seemed possibly or probably to be of value, in connection with the special problem of mechanical traction in London. I have very great pleasure in acknowledging that during these visits made on your behalf I have received most valuable information and courteous help on all hands from engineers, tramway officials and manufacturers, for which I am greatly indebted.

I do not propose to describe in detail any of the visits which I have mentioned, but will confine myself solely to dealing with the matter as it affects London and as it has been referred to me. If your committee wish to have before them detailed descriptions of systems used elsewhere I shall be very glad to add them to this report at any time, but these are probably the less wanted as very excellent descriptions of some of the most important works have recently been placed before your council in the illustrated report drawn up by one of their members, Mr. J. Allen Baker.

(*a*) As the use of steam and cable for the trams is specifically excluded from the reference to me, there remain only, as systems of mechanical traction, the use of gas or compressed air, or of electricity.

As to the two first, if they could be successfully carried out on a large scale, they would certainly have the advantage that the cars would be self-contained and independent of each other or of any overhead or underground work. Any breakdown would therefore be that of one car only and would not affect the general system. I consider that this is a real and great advantage, and an advantage quite sufficient to outweigh smaller drawbacks if the systems in question were in other respects sufficient and satisfactory. Unfortunately, however, neither of them has yet attained sufficient success to warrant me in recommending their use on London tramways in the present state of the engineering problems connected with them. The cars to be used in London must be so large and heavy, and the power required in each so considerable, that the use of reciprocating engines (whether gas or compressed air) of sufficient power as motors is accompanied by many difficulties; in fact, I do not think that really suitable engines for this particular purpose have yet been designed. On a small scale, gas trams are running with considerable economy in the north of England, where I have examined them, and compressed air tramcars are going to be tried for a portion of the cross-town traffic in New York. I had the advantage of seeing these last cars during my visit to America, but they were not at the time in actual work.

Further, as to the use of gas or compressed air, I think I need only point out that if during the time occupied by the construction and running of your experimental line such advances should be made in the matter of gas or air engines as to render it advisable to consider this matter further, tramcars so propelled could quite easily be worked along with others on your lines in case circumstances arose which rendered such trials in any respect desirable.

As to the use of electricity, there are, as you know, various systems possible and in use. These are—

1. The ordinary overhead system, in which the current is carried from an overhead wire to the motor, and returned by the rails themselves to the station.

2. The underground conduit or slot system, in which (with the exception of one type) both conductors are insulated and are carried in a conduit underground, from which the current is transferred to the motor in the car by means of a plough working in a slot in the roadway.

3. Various underground surface contact systems in which no slot is used.

4. Systems using batteries as a sole means of propulsion, or batteries in combination with overhead conductors.

Taking the above possibilities in electric traction in the order in which I have mentioned them, the overhead system is, of course, by far the most used. Its great advantage is that it does not require any special interference with the roadway beyond that necessary for laying the lines of the tramways in any case;* and, further, that more experience has been obtained in connection with this than in connection with any other system. When carried out as roughly as it has frequently been carried out in America, its cost is very much less than that of any underground system. Carried out, as it is necessary to carry out such a system in this country, the difference of cost is not nearly so great. This difference will always, however, be considerable in cases where there are a great many pipes below the road near the surface which have to be shifted or otherwise dealt with. For this reason the overhead system has naturally commended itself to private tramway companies, and also to municipalities in comparatively small towns where the traffic could not be expected to be sufficiently large to pay on an increased capital. The overhead system is capable of giving any reasonable amount of power and any required speed of cars.

In straight roads or streets its disadvantages are at a minimum, the most obvious being the line or lines of poles (in London streets there would generally have to be a line on each side of the road), with the span wires connecting them, the trolley wires, &c., these being at a height of something like 20 feet from the road. Apart altogether from the much vexed question of appearance—as to which there is so great a difference of opinion—I cannot help doubting whether any system of overhead wires can really be regarded as likely to prove a permanent and final solution of the traction problem in a great city like London. But leaving aside this general question, I have to

* In this country the feeders would, of course, be laid underground, but these do not require any such depth of excavation as to be seriously inconvenient.

Digitized by Google

point out that at crossings and street junctions (of which there are an enormous number in the tramway systems of London) the trolley system is inevitably accompanied by such a metallic network overhead as in my opinion to put it altogether out of the question in busy London streets. If any private company asked permission from a committee of the London County Council to erect at any one of a dozen junctions which are shown on the tramways map, such arrangement of poles, span wires, stays, guys, conductors, &c., as are necessary with an overhead system, and as are to be seen in certain cities, I feel certain that the proposal would be met by an absolute and unconditional negative. So far as my own opinion is concerned I do not think that it would be advisable or even permissible to use such a system in such places as I have mentioned. This difficulty affects nearly all the tramways north of the Thames, and it affects the South London tramways over an area roughly about two miles wide, and parallel to the course of the Thames, between Deptford Reach and Chelsea Reach.

South of the Thames and of the limits which I have just mentioned, long lines of trams radiate into suburban or semi-rural districts, these lines being mostly straight, along broad roads and free from junctions. In such cases the disadvantages of the overhead system are at a minimum, and its comparative advantages are greatest. As I shall have occasion to point out later on there is no engineering difficulty whatever in using a mixed tramway system, *i.e.*, partly underground and partly overhead. Whether this is worth while in the case of London is no doubt a matter for very serious consideration, and one which must be, to a considerable extent, decided by the nature of the roads along which the trams are to run and the details of the systems proposed.

I should point out that in any case the overhead system must practically use the rails as return conductor, and must therefore be an earthed system.

2. The underground conduit or slot system is the only one now used in New York, and is partly used also in Washington, in Buda-Pest, in Berlin, in Paris, &c. It is now 12 years since it was first tried in Buda-Pest. The system adopted there was in certain respects tentative, and is in certain important points quite unsuitable for London. Nevertheless, this original system, which is one of the earliest constructed of electric lines anywhere, has worked well and economically ever since its construction, and quite lately it has been much extended, both by the original company, and by a second company following the example of the first one, but with such improvements as later experience has suggested. The American experience in the slot system is more recent, and the results there have also been thoroughly satisfactory. I am glad, therefore, to be able to say, as the result of my examination of the present state of underground electric trams, that the laying out and working of lines on a slot system has already been carried out successfully on a very large scale. Moreover, it must be said that this success has been obtained in spite of a most singularly persistent and not very easily understood opposition. As a matter of fact the cost of power on the two systems (and, what is of equal importance, the cost of maintenance) is practically the same. The drawback of the underground or conduit system is that it certainly costs more per mile of line than the overhead systems. The chief engineer of one of the principal companies using both systems gave me as his experience that where the overhead system had to be provided with underground feeders and with such handsome poles and other appurtenances as would meet the approval of his municipality, the actual difference in cost between the two systems was very inconsiderable. And I have no doubt that the difference has been in the past, for various reasons, very greatly exaggerated. At the same time, however, in addition to the actual increase of capital expenditure due to the system itself, there must be in a place like London very considerable additional expenditure in many places due to difficulties caused by gas and water pipes, &c., which will have to be lowered or shifted or replaced. I have no doubt, therefore, that it is right at this stage to anticipate that any underground system will cost considerably more per mile of line than even a first-class overhead line. I will deal further with this question later on, but here need only point out that the actual amount of the difference in cost will depend on the amount of care given to the details of the design and construction of the underground conduit, in special reference to the particular circumstances and conditions of the London streets.

As to the conduit system itself there are two chief types in use. In one, one of the running-rails is made double, and the slot for the plough is carried down between its two halves, so that the running-rail itself lies directly above the conduit carrying the conductors. In another system the conduit lies in the middle between the rails, and the slot rail is therefore in the middle between the running rails, and is entirely separate from them. In the original Buda-Pest system the slot was about 1¼ inches wide, and even now in Brussels the slot is about 1¼ inches wide, and of still greater width at the points. Such an arrangement would no doubt be quite inadmissible in this country, and I must say that it appeared to me in some cases dangerous. In New York, Washington, Paris, and other places where the centre slot is used it is only about ⅞ inch wide—a breadth which is not the slightest hindrance or danger to any traffic.*

The conduit system has insulated conductors throughout—that is to say, it does not use the rails or earth as a return. I think this is undoubtedly an advantage so far as it goes, as it obviates as completely as in the case of electric light companies, the possibility of electrolysis due to leakage currents and the disturbance of telegraphs or telephones. The concrete below the central conduit is generally from 2 feet to 2 feet 3 inches below the road surface. Unless large pipes occur within this depth there will not be much trouble; it is only with large pipes occurring nearer to the surface than this that serious trouble is found. I think, however, that it is possible by careful design somewhat to reduce the depth of the conduit, and so reduce the trouble and expense due to this cause.

3. In surface contact systems there is no surface slot rail, but a series of studs, or buttons, or a continuous solid centre rail (divided electrically into sections), whose upper level is somewhat above that of the roadway between the running rails. These studs or rail sections become alive only when the car is actually passing over them and when they are rubbed by a skate or brush carried by and underneath the car itself. In these systems the return current is carried back by the rails exactly as in the ordinary overhead system, so that they have not the advantage of an insulated return. I have examined the working of a number of surface contact systems, some running on a commercial scale, some only experimentally. As compared with overhead lines they have, of course, the advantage of doing away with all poles, wires, &c., above ground. As compared with the conduit system, they are in general cheaper,* certainly in cases where the conduit system requires the removal of pipes under the roadway, for the surface contact system necessitates comparatively little excavation. The studs, or buttons, do not at all seem to be in the way of ordinary traffic, although I think that the raised centre rail which has been proposed in several cases might probably be found inconvenient. In most of the contact systems, however, a serious disadvantage, a disadvantage especially in our moist climate, is the fact that the working of the system depends upon the permanence of a very large number (from 300 to 1,500 per mile of single line) of coils of fine wire placed in switch boxes or in separate chambers underground, along or beside the line. I have been most anxious not to attach an exaggerated importance to this point, but after full consideration I must say that until it is experimentally demonstrated that these coils will remain permanently in good order and well insulated under the conditions of ordinary road traffic in our own country, they appear to me to constitute a serious drawback to the systems in question.

I must add, however, that there is a class of contact systems differing from those I have just mentioned in having electro-magnetic coils only upon the cars and not underground at all. Such coils are very few in number, and the failure of any of them would cause the failure of a car only, and not of a section of line, while they are much more accessible and readily tested and examined than coils placed permanently underground. No large experience has yet been gained in connection with such a contact system as I have just mentioned, but the experience, so far as it has gone, has been favourable, and it appears probable that a system based on this principle may be carried out successfully even under English climatic conditions. A good deal, however, has still to be done in order to work any such system into a form suitable for use under the conditions of London traffic. Equally with the other contact systems, there would in this case be a return by the rails.

4. Batteries of accumulators are used sometimes as the sole means of propulsion (in which case the battery is removable and is taken out of the car after a certain length of journey and replaced by another), or as part of a combined system, where the batteries are charged from the overhead portions of the line as the car is running upon them. In the latter case the batteries are never taken out of the car except for the purpose of overhauling. A battery car has the advantage that it may be made self-contained, so that a breakdown would be that of the car itself and nothing more. The batteries add, however, very greatly to the weight of the car (from 2½ to 4½ tons), their maintenance is very considerable in most cases, and at the best they are practically only suitable for use on level lines as in Hanover or in Ghent, in which latter place especially their use appears to have been attended with great economy, although of course it is only on a small scale. As with gas and compressed air, it will be possible for you at any later time to give a trial to a battery car or cars on your experimental lines if it seems desirable to do so, but I do not advise you at present to enter into any experiments yourselves in connection with this system of traction.

In concluding this section of my report I have to say, after examining very many overhead and underground lines in large cities, and especially after seeing the two systems frequently side by side in the same city, that the general convenience of having the roadway absolutely clear of all overhead obstructions, especially at important street junctions, seems to me so great that even if the extra cost were much more than it is actually likely to be, I think that the London County Council ought to adopt over all the central parts of their lines, an underground system—that is to say, a system in which overhead wires are entirely dispensed with. As to the much vexed æsthetic part of the question, I do not wish to say anything. But I feel certain that in such a large and wealthy city as London, a city where the tramway traffic will be enormous, and especially a city where the tramways are actually in the hands of the municipality, any such overhead arrangements as are inevitable at such places as I have indicated would never be tolerated as more than a makeshift. I believe that if for the sake of saving in the first cost they were to be adopted in London at present, there would before many years be a peremptory demand that they should be pulled down altogether and replaced by something free from these obvious drawbacks.

As to section (*b*) of the reference, I am very glad to understand that the Highways Committee propose to apply mechanical traction in the first instance to an experimental line. That is, as I understand, that they propose in the first instance to apply mechanical traction to only a certain detached section of their whole network, in order to gain such experience in the special conditions of London

* As to this I may mention that in Edinburgh, where a cable line is being laid, and where there is therefore a centre slot rail along the track with a slot ⅞ inch wide, the surface of this slot rail is the favourite line for bicycle riders to follow, as being the smoothest and best part of the street.

* But this would certainly not be the case in several of the systems I have actually examined, unless the conduit were made disproportionately expensive on account of the removal of the pipes.

Digitized by Google

traffic as may guide them in completing their scheme later on. Such a section or experimental line should be of sufficient length to be in itself a paying concern, and therefore it should be on a well-frequented route. It ought also to be on a route containing good examples of any such surface difficulties (I do not refer to underground pipes) as may be expected to occur in other parts of London. A total length of five or six miles would be sufficient—a much smaller length would hardly be desirable. I find from the drawings kindly sent me by Mr. Gunyon that the line originally proposed for this purpose is already the site of three 30-inch water mains at no very great depth below ground, otherwise the line proposed was in every way suitable. I think, however, that it would be a pity at this stage of the work to deal with a portion of road offering such special extraneous difficulties as this particular road appears to offer. If, therefore, Mr. Baker can, from the point of view of traffic generally, suggest some other line, I believe it would be advisable to adopt it, supposing always that it is not found as difficult to deal with as the first one.

In view of the fact that the County Council have already sanctioned the proposal of a private company to bring a portion of their overhead lines within the county of London, and that this overhead line appears to be in the hands of excellent contractors, and will be subject to the approval of the Council's engineeer, and always accessible for examination by members of your committee, I do not think it will be worth while to fit up any portion of whatever line is chosen for experiment with overhead conductors. I have therefore to recommend to you that a scheme be worked out for fitting up such a line as I have just mentioned with a conduit system, having both conductors insulated. The details of this system will, of course, require very careful working out before tenders are obtained. On such a length of line as that proposed it will be found quite possible—if, on going into details, it is also found desirable—to try more than one arrangement, so as to determine the best for final use. On the same line there could also be tried—if in the progress of the work it seemed desirable—a contact system based on the principle which I have mentioned above.

I have already pointed out that on any experimental line constructed by the Council self-contained cars of any type (gas, compressed air, or battery) could be tested if it seemed desirable to the Council to allow such experiments to be made.

The total power required to work the cars upon such a section of line as I have suggested depends, of course, upon the number and weight of the cars. Assuming, however, that the line is six miles in length, and that there is a two-minutes' service of heavy cars during the busiest parts of the day, running with a maximum speed not exceeding 10 or 12 miles an hour, you would require to provide something like 2,000 H.P. for the work. I fear that it is hardly possible for you to buy continuous current to this amount from any of the private companies supplying electrical energy on the south of the Thames, or at all events, to buy it at any cost approaching that at which you could supply yourselves from a station of your own. This is especially the case, as, while any such arrangement could only be of a temporary character, it would entail upon the company supplying the energy the purchase of a large amount of special machinery. I think, therefore, that it would be most advisable and economical for you to have the plant designed and specified especially in such a way as to form part of the complete scheme which you will be carrying out later on. And if possible, it should be put down on a site which should be the site of one of your permanent power stations, so that it might not have to be removed later on. I quite recognise, however, that it may not be possible to make sure of obtaining this last condition, in which case it must be made certain that the whole of the plant can without more than reasonable inconvenience be shifted into its permanent position later on.

I think I need not point out to you that the questions of the type and weight of the cars, and especially of the speed of running, must be dealt with and settled as soon as possible, as upon these points depend so very much the whole electric equipment of the line.

(*c*) In conclusion, as to the whole matter of mechanical traction in London, I have to say that it is necessary to remember that the conditions of working in London are and will always be very different from those which exist either on the Continent or in America. In some respects the differences will make our working easier, in others more difficult. In particular I should think that it was improbable that the County Council or the police authorities would permit any such speeds to be reached as are quite common elsewhere. I am afraid that it must be admitted that the high speeds which I have found common in very many cities, and which are certainly popular with the people, have been and continue to be the cause of very numerous accidents of a kind which would be considered in this country most serious, and which would, in fact, be sufficient if they occurred here to result in the immediate prohibition of the fast running to which they are apparently due. The rough arrangements of wooden posts and overhead feeders, which are still visible in the streets in many places, would be also impossible here. The breadth of slot also which is used on the Continent would rightly be considered here as inadmissible, if not dangerous to traffic.

In respect also to the amount of the tramway traffic, I wish I could anticipate that it should be as large in proportion as the traffic obtained elsewhere. I have examined, for example, the traffic on 37 of the largest American lines for which statistics are published, and I find that on the average the tramways of these 37 towns carry their whole population in less than six days, and in the cases of large cities, such as Boston, New York, Minneapolis, Troy, &c., a number of passengers equal to the whole population is actually carried by the tramways in less than three days. This is the more surprising when one remembers that the travelling in an American tramcar is one of the most uncomfortable experiences possible, the car being at all busy hours of the day crammed with people standing up as well as those seated in what we consider a legitimate manner. But although it can hardly be expected that the trams of the London County Council shall, for a long time to come, carry two million passengers per diem, it is yet a matter of, I believe, universal experience in this country, so far, that a change from horse cars to the greater speed and comfort of mechanically worked cars is always accompanied by a very large increase in traffic.

I understand that at present, even with your horse tramcars, the difference between receipts and expenses amounts to something like 3½d. per car mile. With mechanical traction your expenses will certainly be diminished and your receipts will be largely increased, unless you balance the greater number of passengers by a very large reduction in average fares, as I presume before long you would wish to do.

It has not been possible, in the time at my disposal, to make accurate estimates of cost, but I may put before you a few approximate figures as some indication to your Committee of what the whole matter means. The present length of tramline in London may be taken roughly as equivalent to 200 miles of single track. On this 200 miles, when working electrically, you might probably have something like 500 cars running, and these cars might make not very far from 20,000,000 car miles per annum. Taking the cost of the lines, cars, and power stations, merely for the sake of assuming some figure, at £15,000 per mile of single track, the total value of the whole tramway system would be £3,000,000 sterling, on which, therefore, £150,000, roughly, would be necessary to provide interest and sinking fund. This, you will see, amounts to 1·8d. per car mile, or just about one-half the present difference between your working expenses and receipts. I hope therefore that the committee will find themselves able to believe that the enterprise in which they are about to embark is one which will not only be for the benefit of Londoners generally, but one also which will pay its way, and on which therefore there would seem to be no reason for grudging such expenditure as to make the whole scheme one of a kind suitable for and worthy of the greatest city in the world. I think it is worth while to emphasise this point because of what I conceive to have been undue emphasis which has been sometimes laid during the last few years on the additional capital expenditure necessary for a conduit line as compared with an overhead system. While admitting to the fullest extent that for a company, whose first business is to earn dividends for its shareholders, the overhead system will appear the most advisable, and whilst admitting also that for small towns where the traffic cannot be anything like as much as, and where the expenditure may be proportionately much larger than in London, it may be desirable on public grounds to limit the expenditure to the lowest possible amount, yet, in the case of London itself, I submit that these considerations have not such weight. Each £1,000 per mile of additional capital cost would (on the basis of the traffic which I have just mentioned) carry with it capital charges amounting to about $\frac{1}{8}$th of a penny per car mile, from which figure the additional charges corresponding to any probable increase of capital cost per mile can be at once estimated. I do not think they should be such as to prevent you from carrying out an underground system, which would, I believe, be permanently satisfactory to Londoners and worthy of the city and its governing body.

I should add finally that if it should be decided to carry out the long extensions to the south of London on an overhead system, there is no difficulty in arranging the cars so that they can run from underground to overhead and *vice versâ*, either with no stoppage at all at the point of change, or with a stoppage of only a few seconds.

I remain, your obedient servant,

ALEX. B. W. KENNEDY.

A NEW WHEATSTONE BRIDGE.

THE form of Wheatstone bridge shown by fig. 1 is a pattern which is being manufactured by the Scientific Instrument Company, Limited, of Cambridge, and patented by Prof. H. L. Callendar, F.R.S., and Mr. E. H. Griffiths, F.R.S. It is specially adapted for the measurement of low resistances, and was designed to get rid of some of the sources of error met with in the ordinary form of bridge.

The arrangement consists of a wooden base on which are mounted seven porcelain plug holders, also bridge and galvanometer wires of platinum silver, and the necessary terminals for battery and galvanometer connections, &c. One end of the bridge wire is held by a brass spring, the tension of which can be adjusted in order to take up any looseness in the stretched wire due to shrinkage of the wooden base or to the lengthening of the wires due to change of temperature. This brass spring is adjusted by means of a screw set midway between the fixed end of the spring and the end to which the bridge wire is connected.

Connection is made between the galvanometer and bridge wire by means of a simple but effective contact maker. This consists of a small felt-padded ebonite button placed on a steel spring. This is pressed on to the bridge and galvanometer wires, which are in their turn depressed on to a small piece of platinum silver wire set at right angles to them, and fixed on to the sliding piece which carries the vernier, thus completing the galvanometer circuit. It has been found in practice that this form of contact maker does not damage the bridge wire to the same extent as the old form of contact, in which the contact piece was pressed direct on to the wires. Moreover, any shake or uncertainty which may occur when the contact piece is movable is avoided. Again, tension in the wires also tends to break the contact as soon as the spring is released. The carrier runs between guides in which it is held by means of a weak spring. The galvanometer circuit can be kept closed by means of a small clamp screw mounted on the contact maker.

Stout rods are used for connecting the bridge wire to the coils and

Digitized by Google

to the leads, so that this resistance is small compared to that of the coils. These coils, which are made of platinum silver, are wound loosely in small hanks, and are suspended in air from the end of their connecting rods, set in a box at the back of the base board. The coils are seven in number, and are each put in circuit by removing a plug. Every plug contact is made in a porcelain pot, in which is cast a special fusible metal into which the plug is fitted, the contact surface of the latter being 3 centimetres in length, and so made that when in position the top part of its taper is below the upper surface of the fusible metal, thus avoiding a shoulder being worn on the cone of the plug, and ensuring a perfect contact. It will also be seen that each contact being independent of its neighbour, the withdrawal or inser-

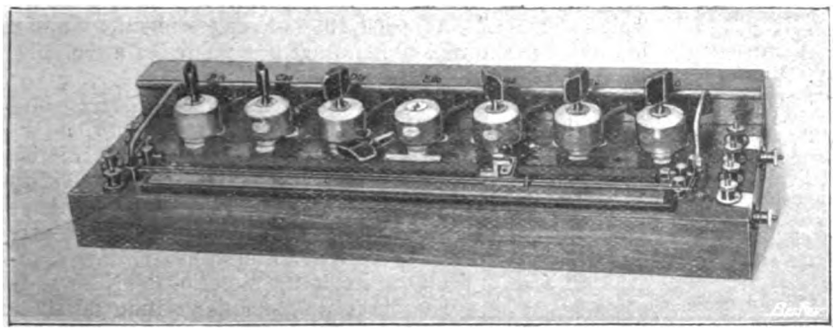

FIG. 1.

tion of a plug does not disturb the contact of either of its fellows, even if the plugs are pressed in with great force. The copper leads which join the coils to the plug blocks are specially designed to avoid any alteration in the length of copper being made when one or all the coils are in or out of circuit. This is effected by an ingenious device due to Mr. Horace Darwin. The copper connections are made in the form of the letter X, being fixed together where the lines intersect, thus leaving four equal arms. The front two are cast directly into the fusible metal sides of two consecutive plug pieces, one arm being attached to the right hand portion of the left hand plug hole and the other to the left hand half of the right plug contact. The back arms are connected to the ends of two consecutive coils. Fig. 2 fully explains this:—

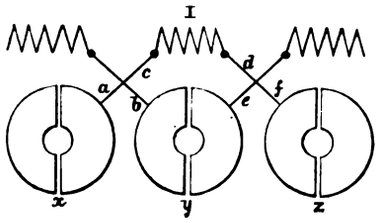

FIG. 2.

x, y, and z are three plug blocks, connected by the copper rod a, b, c, d, e, f, which form equal quarters of the X connections. Supposing the plug is removed from y in order to put the coil I in circuit, then the length of copper connection in circuit is equal to f, d, c, a, but should this plug be in, then we have an equal length of copper in circuit in the sections f, e, and b, a.

The coils are arranged in the form of a binary scale with 10 units as the lowest coil, and taken to the sixth double of this coil, viz., 10, 20, 40, 80, 160, 320, and 640. Each coil has a corresponding letter, B, C, D, E, F, G, and H, it having been found that this lettering frequently prevents errors in the entering of observations. Moreover, as any one low resistance can only be made up by the combina-

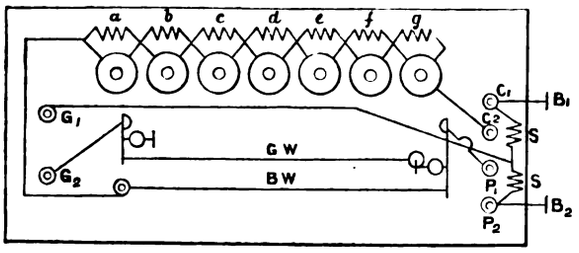

FIG. 3.

tion of certain definite resistances, it is possible to re-check the corrections to the coils with a degree of accuracy unobtainable in a box in which the coils are numbered 5, 10, 15, 20, &c., as a resistance in the latter box may be made up by two or three combinations of resistances. As the box is essentially one for low resistance work the unit is taken as one hundredth part of one ohm, so that coil H (640 units), is in reality 6·4 true ohms. The bridge arms are adjusted to exactly the same resistance, viz., 10 ohms (1,000 units), and being wound together and embedded in paraffin wax, any change in temperature affects both arms equally.

The arrangement of equal arms greatly facilitates the measurement of any resistance, as when G is balanced and the scale reading taken, then in order to obtain the true resistance at x, it is only necessary to subtract or add the bridge wire reading to that of the plugs (according as the reading is to the left or right of the zero point on the scale). The box is so arranged that the reading on the scale is subtracted from the plug resistance when the balance point is to the left of zero, and added when to the right. The scale is divided into millimetres, a centimetre on the bridge wire being approximately equal to one box unit.

The method of compensating for the external leads is, perhaps, the most important improvement in this box, and deserves special notice. These leads are not made up in a pair, as is generally the case, but consist of a stranded conductor composed of four stout flexible leads carefully interwoven with one another. Two of these leads are connected to the resistance to be measured, and the other two, which are short circuited near the resistance, are placed in the opposite arms of the bridge. Thus any changes in the resistance of the leads, owing to differences in temperature, are compensated for, and no corrections have to be made on the score of leads. The leads have copper lugs soldered at each end after they have been adjusted for equality. Thus with the most ordinary care there is no danger of this equality altering. The true zero point on the bridge wire can readily be determined by short circuiting these two pairs of leads.

Fig. 3 is a general diagram of the bridge.

Everything being compensated for in the way described, a high degree of accuracy may be attained, and though the bridge, fig. 1, is styled a "student's bridge," yet it is, when carefully calibrated, capable of doing really excellent general work. It can be tested and calibrated on itself, as the value of the coils can be found in terms of one another by a method, details of which are supplied with each instrument. It is thus only necessary to know the value of one coil in true ohms to be able to obtain the absolute calibration of the whole apparatus.

The above is only one pattern of this special bridge. More elaborate designs have been completed, with which some of the finest possible resistance work ever attempted has been accomplished. Among other improvements the coils consist of bare platinum-silver wire wound on mica frames and immersed in a high insulating oil. The oil bath is fitted with stirrers, and it is possible to determine the temperature of the coils with a much higher degree of accuracy than if they were embedded in solid paraffin.

An excellent type of this box may be seen in the physical section of the South Kensington Museum.

LIGHT ELECTRIC RAILWAYS IN MIDDLESEX.

Proposals to Gradually Link up the County by Means of a Network of Lines.

The Middlesex County Council is jealous, and justly so, of the independence of its own county, and when the London County Council recently suggested the appointment of a joint committee of the two bodies "to consider and deal with all matters relative to the promotion and carrying into effect of light railway schemes affecting both Councils," the astute members of the former body thought there was an insidious movement behind the proposal. There was no doubt on the matter. The London Council thought, or at least the Highways Committee were under the impression, that it was the desire of the Middlesex Council that the two bodies should act in unison in settling and promoting schemes for light railways to be constructed in Middlesex in connection with the tramways in London, with a view to ultimately coming to some arrangement as to the method under which such light railways should be administered after their construction.

This impression, which was founded on an erroneous basis, was dispelled by Sir Richard Nicholson, clerk of the Middlesex Council, who informed the London Council that it was impossible to understand how it could be imagined that Middlesex would act in any way in conjunction with London, except upon the distinct understanding that each county council should be the light railway authority in its own county. Sir Richard added that the County Council would not reverse its avowed policy from the commencement "of admitting no interference from any outside authority in its county." This statement places the whole matter in a nutshell. London wanted to unwarrantably interfere in Middlesex, but London was not sufficiently conscientious as to ask Middlesex in return to interfere in the metropolitan area. It would at once have cried, "Hands off!" if the suggestion had been made. The Middlesex County Council is, however, ready to enter into negotiations for an interchange of traffic between the two counties. What more does the L.C.C. want? In a moment of pique at this rebuff the L.C.C. resolved to support one of the District Councils in opposing a light railway scheme projected by the Middlesex County Council. It will be interesting to learn what the Light Railway Commissioners will have to say on the unseemly attitude of the L.C.C. in this respect when the local inquiry takes place.

Digitized by Google

In the meantime it should be mentioned in connection with the 21 light electric railway schemes proposed by the Middlesex County Council, that Mr. James Bigwood, M.P., the chairman of the Parliamentary Committee, has been authorised to obtain the advice of an electrical engineer, in addition to that of Mr. Wakelam, the county engineer and surveyor, in the elaboration of the schemes. The latter gentleman has also been directed to prepare the necessary plans and sections and books of reference for deposit with the Light Railway Commissioners.

Of the 21 light electric railways proposed for Middlesex, the County Council has decided to apply to the Light Railway Commissioners, in conjunction with the Metropolitan Tramways and Omnibus Company, for a provisional order to construct 10 of these lines, these being included in the Middlesex Light Railways Order, of which public notice has already been given. One scheme relates to a line in Friern Barnet and Finchley, which the former District Council suggests should be substituted for a section included in the Middlesex order; four others refer to a line from Harlesden, through Wembley, Harrow-on-the-Hill, and Wealdstone to the foot of Stanmore Hill; whilst the remaining six proposals affect Isleworth, Twickenham, Teddington, Hampton, and Hampton Wick. It may be remembered that the London United Tramways Company promoted lines in the latter parishes, but the Light Railway Commissioners declined to grant the desired order.

In conclusion, it should be mentioned that the object aimed at by the Middlesex County Council is the gradual construction of a network of light electric railways throughout the county, so as to link up the most important districts and at the same time afford a connection with the London tramway system. The only serious difficulties likely to be encountered are those put forth by some of the district councils, who not unnaturally desire to be considered in regard to the proposed routes, terms of lease, and other matters. These points are receiving the attention of the Middlesex County Council, and it is hoped that all obstacles will shortly be overcome. The hostile attitude of the L.C.C. can hardly be expected to in any way affect the ultimate result; it cannot possibly have any *locus standi* in Middlesex, which intends to preserve its independence, whilst at the same time being prepared to discuss ways and means for an interchange of traffic at the boundary lines of the two counties.

REVIEWS.

The Value of Electrical Treatment. By Julius Althaus, M.D., M.R.C.P. Lond., M.R.I. Third edition. Longmans, Green & Co., London, New York, and Bombay.

In 1873 Dr. Althaus published "Medical Electricity," a work which, from the medical standpoint at least, seems to have been more than abreast of its time. In 1895 there appeared the first edition of the volume now under notice, and it was a matter of comment at the time that it contained no adequate recognition of the great progress in electro-therapeutics that had been made in the long interval since 1873. For example, sinusoidal currents, high frequency currents, and the methods of Apostoli were noticeable only by their absence, although these procedures were at the time very generally known. "Metallic electrolysis" was not mentioned, and the short notice of cataphoresis that did appear, by no means atoned for the opinion expressed in the volume of 1873 (p. 708) that the view that "electricity may serve to introduce drugs into the system is likewise untenable." We are glad to see that in the present edition the above-named gaps are to some extent filled in, and that the writer, profiting perhaps by criticism on his first edition, now notices a certain portion, at least, of what he condescends to call "the quiet and useful work" that has been done since 1873. There is even a chapter on current from the main, a title which might almost have been put in inverted commas, as it is now many years ago (1891) that a writer in the *Lancet* first drew attention to this subject under this title, and has continued to do so at intervals ever since.

In this connection it may be incidentally mentioned that it was not until after the publication of one of these articles that the instrument maker referred to by Dr. Althaus introduced the shunt principle into his rheostats.

Of all the forms of electricity for medical purposes, Dr. Althaus still maintains, and doubtless with excellent reason, his unswerving allegiance to "the battery." Indeed, in describing electrical energy in its more modern forms, although he deals with these at some length, his descriptions fall far short of impressing the reader with the idea that he has actually handled these currents himself, or that even he quite apprehends what is known of their phenomena. Speaking of currents of great frequency and high potential, by means of which intensities may be passed through the body, which at a lower frequency might be fatal, he recognises an analagous fact in the spheroidal condition of bodies; for example, in molten metal at white heat not injuring the hand plunged into it, whereas only at a red heat serious injuries would follow. Those of his readers who understand the physics of the phenomena in question, may perhaps be excused if they fail to see the force of such an analogy.

It is not our province to criticise the medical part of this book; we can only regard its curative achievements with feelings of wonder and praise, and also with a consolation akin to that which the devout believer finds in the "blessed" word "Mesopotamia." At page 49 we learn that in the human brain there is a region known as the "anterior association centre." It is this centre "which directs our actions, enables us to judge our own conduct, and tells us what is right and what is wrong. It therefore constitutes the δαιμονίον (the divine warning voice), of which Socrates speaks in Plato's Euthyphron. Disease of this centre changes the perception of the Ego as an active being, and diminishes or annihilates personal initiative." A disordered condition of this centre appears in "deficient self-control, diminished initiative, indecision, and difficulty in fixing the attention." Now it is not without misgiving that we recognise certain of these symptoms in ourselves, and even in our friends. Our wandering thoughts on these summer days point to a "difficulty in fixing the attention," and certain unsatisfactory transactions with city friends can only be explained by an unfortunate disability (on their part) to "distinguish between what is right and what is wrong." It is only too evident that things are not quite as they ought to be with our respective "anterior association centres," and it is no small relief to find that all this, serious as it is, may be set right by a trifling expenditure of $\frac{2}{10}$ths of a milliampere of continuous current from the head to the hand, applied according to the author's methods.

A little further on (p. 60) we find that "our mean lifetime is at present about 50 years, but the complete cycle of physiological life to which we ought all to aspire is 100," and it is with feelings of gratitude we note that we can be helped on towards attaining our "century" by a cautious use of continuous current to the brain—according to the author's methods. "A week or two after the commencement of such a treatment the energy of the system is habitually found to have been considerably enhanced. The old man takes fresh interest in the affairs of daily life . . . . his peevish and querulous temper is no longer a source of trouble to his friends. . . . . Quite recently a veteran actor who delighted the last generation by his magnificent Shakespearian performances, told me after a few applications, 'I no longer crawl but walk;' and a composer of music, of advanced age and bowed down by many infirmities, volunteered the remark, 'I no longer walk but fly.'" The "Value of Electrical Treatment" is surely no adequate name for such a book as this. "The miracles of medical electricity" would in our opinion be a title none too strong. At least one thing seems clear. Could a certain eminent "electrician," who so long adorned a conspicuous corner in Oxford Street, once more return to the scene of his labours and success, it would only be to find that in comparison with the achievements of the legitimate practitioner, he is no longer "in it."

Pocket Book of Useful Formulæ and Memoranda. By Sir Guildford L. Molesworth and Henry Bridges Molesworth. 24th edition. London: E. and F. N. Spon, Limited, 125, Strand.

In the preface to this issue we are informed that neither has labour been stinted nor counsel disregarded in order to render the 24th edition worthy of its predecessors.

The electrical portion of previous editions was struck out of the 23rd edition, as it was the intention of the authors to have published a separate electrical pocket-book. For reasons which it is unnecessary to state, that intention has been abandoned, and an entirely new electrical section has been now added to the 24th edition.

It is somewhat to be regretted that the authors' intention of publishing a separate electrical edition was not carried out, not, however, from the view of the possibility of such an electrical edition proving a valuable compilation, but from the fact that it would have relieved the present issue from

Digitized by Google

what can only be characterised as a very unsatisfactory production. Not only is a large amount of the matter included of an unpractical nature, and almost useless to the practical engineer, but we come across such an astonishing display of errors as one could hardly credit. Turn, for example, to page 787; we should have thought that every schoolboy knew what a submarine cable was like, yet here we have the most remarkable "Typical Submarine Cable" that was ever devised, and we are constrained to ask, Was it inserted as a joke or in sober earnest? First we have the "conductor" which the author calls the "core," then the gutta-percha insulation, next a "composition," then a "lead sheath"!!!; next hemp, then the armouring, such as was never seen yet on a submarine cable, and finally the hemp serving. The figures illustrating insulators must have been devised from the author's inner consciousness, as such patterns are never seen in practical use. Also the "Telegraph Poles" illustrated are a curious combination of wood and iron. Then we have "Lightning Arresters," "a pile of metallic discs separated by laminæ of mica . . . . the top disc connected with the line, and the bottom disc to the earth." It is a pity that an illustration is not given of this "pile of metallic discs." Next we have "Duplex Telegraphy," in which we are told that "the *current* from line is neutralised by that from the condenser." The description of the differential duplex is also a marvellous display, either of want of knowledge or lack of descriptive power. On page 740 we have a brief table showing "Best Resistance and Deflection for Telegraph Cells," a table which, in the absence of constants, is just as valuable as the dimensional "lump of chalk" of tradition, let alone the fact that the figures given could only be for special cases, and are of no general value whatever. On page 783 we are told, with reference to "Test in Laying Cables," "Leakage is indicated by a *fall* in the deflection of the ship's galvanometer." The "Electrostatic Capacity" test (De Sauty's) which follows, and which is the only one given, is the most unreliable one that could have been selected.

The pages are plentifully bestrewn with matter by H. E. Harrison, which matter, although doubtless perfectly correct, is not generally of a description suitable for practical engineers. Page 752 contains the well-known illustrations of types of winding the field magnets of dynamos. The repetition of these illustrations in every class of engineers' pocket or handbooks is often sneered at by critics, but we maintain that they are very much in place, and should by no means be omitted. Such matter as this, and that on the following two or three pages, is distinctly useful, and if the whole electrical section had been compiled on such lines it would have been of considerable value. In the pages following where Messrs. Harrison and Russell appear, the want of discretion in the selection of matter becomes apparent. We venture to say that the omission of such matter would be a gain rather than a loss. On page 756, a frequency of 16½ is given as the best for utilising continuous current dynamos for synchronizing motors!—and an absurd diagram of a projector arc occurs on page 786. Such diagrams as that given on page 765, showing the "increase per cent. in the resistance of hard copper with increase of temperature," are much better dispensed with, and a short table of numerical values and a formula given instead. Graphic representation is all very well, but it has been, in our opinion, very much overdone. It often seems to be forgotten also that a series of curves which, drawn on a large scale, are of value, become practically useless when reduced to pocket-book size.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1899.

Compiled expressly for this Journal by W. P. Thompson & Co., Electrical Patent Agents, 322, High Holborn, London, W.C., and at Liverpool, Manchester, and Birmingham, to whom all inquiries should be addressed.

15,644. "Electrical ignition apparatus." F. Kupper. Dated July 31st.

15,663. "Improvements in governing devices in connection with fluid pressure engines in combination with dynamo-electric machines and other machinery which requires accurate governing." R. P. Isaacson. Dated July 31st.

15,677. "Improvements in supports for galvanometers and other delicate instruments." J. H. May. Dated August 1st.

15,699. "Electric fuse outfit." H. E. Davis. Dated August 1st.

15,705. "Improvements in or relating to electric meters." J. H. Barker and J. A. Ewing. Dated August 1st.

15,717. "Improvements in fusible cut-outs." The British Thomson-Houston Company, Limited, and E. B. Wedmore. Dated August 1st.

15,720. "Improvements in electric arc lamps." Crompton & Co., Limited, A. J. Hodgson, and C. F. Tubbs. Dated August 1st.

15,744. "Improvements in or connected with electric regulating switches." O. D. Lucas. Dated August 1st.

15,807. "Improvements relating to the terminals of electric batteries and the like." A. C. Wright. Dated August 2nd.

15,816. "Improvements in electro-magnetic rail brakes." A. Wilde. Dated August 2nd.

15,882. "Improvements in apparatus for operating two or more electrical regulating switches or resistance devices together or separately." O. D. Lucas. Dated August 3rd.

15,904. "Improvements in and connected with transformer boxes." A. J. Lawson, J. D. Dallas, and E. T. Goslin. Dated August 3rd.

15,911. "Improvements in or relating to electro-magnetic apparatus." W. F. Jones. Dated August 3rd.

15,967. "Improvements in electric arc projecting lanterns." L. Kamm. Dated August 4th.

15,973. "Improvements in and relating to the direct coupling or connection of rotary fans or pumps with electric or other motors or engines driving same." S. C. Davidson. Dated August 4th.

16,005. "Improvements in the method of and apparatus for manufacturing incandescent electric lamps." A. Swan. Dated August 5th. (Complete.)

16,040. "Improvements in electric fuses and electric detonator fuses." G. Smith and D. Corrie. Dated August 5th.

16,055. "Improvements in electric switches." W. F. Jones. Dated August 5th.

16,062. "Improvements in or connected with electric light fittings." H. H. Cooper. Dated August 5th.

16,083. "Improvements in controlling devices for electric currents." H. Cuenod. Dated August 5th.

16,091. "Improvements in electrical apparatus suitable for lighting, cauterizing and other purposes." J. Richardson and H. Ramsbottom. Dated August 5th.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson and Co., 322, High Holborn, W.C., and at Liverpool, Manchester, and Birmingham, price, post free, 9d. (in stamps).

1897.

12,638. "Improvements in means for regulating the voltage of dynamos." La Societe Generale des Industries Economiques. Dated May 21st, 1897. (Date applied for under Patents, &c., Act, 1883, Section 103, March 20th, 1897, being date of application in United States.) In order to regulate the voltage of dynamos driven by explosion engines and other motors, the speed of which varies in different portions of the cycle, a series of resistances is placed in the field circuit, and these are increased or decreased automatically as the speed of the motor varies. A suitable form of apparatus comprises a collector, having a series of contacts connected through resistances to a contact ring, and a brush holder carrying brushes, bearing on the circle of contacts and the contact ring respectively. Either the brush holder or the collector may be fixed to the motor shaft so as to rotate it. The contacts are so spaced and the resistances so graduated as to exactly compensate for the fluctuations of speed of the motor; the arrangement shown is that employed for a four-stroke cycle explosion motor. 2 claims.

12,642. "Improvements in contact fingers for electric controllers." E. C. Parham. Dated May 21st, 1897. (Date applied for under Patents, &c., Act, 1883, Sec. 103, November 18th, 1896, being date of application in United States.) The contact fingers of controllers are formed of magnetisable metal, and are so arranged as to produce an electro-magnet which will blow out an arc, if formed, on breaking contact. The contacts engaging with the contacts on the drum are carried by forks secured to the springs connected to the base. The forks thus form electromagnets and tend to blow out any arc which may be formed when contact is broken. In a modified form, a single arm is employed in place of the fork, and the magnetic circuit is completed through suitably arranged bars. 15 claims.

12,643. "An improved system of conductors for electric railways." E. Lachmann. Dated May 21st, 1897. Electric railways and tramways on a three-wire system. The exposed conductors on which the collectors run, here shown on the overhead system, are alternately positive and negative, and the non-exposed portions are placed alongside. The current is picked up by a number of collectors and between them and the motors on the vehicle an automatic reversing switch is placed to maintain a uniform direction for the current to the motors. This consists of a rocking arm for each collector working over two pairs of contacts and operated by a magnet acting on the coils, which are included in the circuit from the collectors so as to be attracted alternately according to the current. In case of alternating currents this switch is unnecessary. 2 claims.

12,665. "The combined generation and application of electricity supply and the manufacture of salt." H. Tee. Dated May 22nd, 1897. Brine is concentrated in a closed vessel from which salt is removed by rotary scrapers, while steam is generated under pressure to drive condensing engines connected to dynamo electric generators; the current from these may be employed for making calcium in electric furnaces, or other purposes. The concentrating apparatus may be heated by the exhaust steam of high pressure engines, which also operate electric generators, or by gaseous or other fuel. Specifications No. 6,565 and 6,565A, A.D. 1895, are referred to. The brine is contained in vessels having conical roofs and bottoms connected by central openings, and supported by walls which form heating flues under the bottoms. A vertical central shaft carries scrapers. The apparatus is closed at the top by a steam dome, and at the bottom communicates by a valve with a receptacle for the salt; this can be removed by another valve when the valve is closed. Similar apparatus, but with flat floors and roofs separated by steam spaces, is used for concentrating by exhaust steam. In a modified arrangement a single vessel only is used, or two such vessels are placed side by side with one continuous heating flue. The floor in such apparatus may be flat or rise to the centre, and salt receptacles may be provided at the side; a flat door may be stayed to bottom plates, enclosing space for the heating gas, the stays being protected by cast-iron tubes. The scraper shaft may be tubular, to enclose a central vertical stay. 10 claims.

12,810. "Improvements in telephone receiver supports." L. Duque and F. McClelland Cosgrove. Dated May 25th, 1897. Consists of a support for a telephone receiver for holding it in a convenient position near the head of the user. The receiver rests in a cage or basket with two screw sockets, either of which may be screwed to the end of a rod, which slides in a tube, fixed by a hinge-point in the horizontal arm of a bracket attached to the wall, &c. A clamping screw holds the tube in any angular position, and the rod is fixed by a screw. A weight may be hung from the receiver hook when it is desired to keep the receiver in the basket while calling. 1 claim.

12,874. "Improvements in electrical telegraph systems and apparatus therefor." H. H. Lake. (C. G. Burke, United States.) Dated May 26th, 1897. In receiving instruments used on submarine or other long lines for recording Morse or similar signals, the magnet is caused by suitable electric impulses to make a continuous mark in the absence of line current, so that the code signals are indicated by breaks in the line recorded. The signals are sent by a hand-key, or preferably automatically by tape prepared in a special instrument. In order to indicate the spaces between letters and words, long breaks are made in the record, or the last signal of the code for any latter is lengthened or duplicated at a very short distance. A pole changer consisting of a pivoted forked lever working on a tapering or wedge-shaped contact, and operated from the armature of a relay magnet, is used for "clearing" the line; by this special form of contact the duration of the clearing current can be regulated as desired. Similarly the perforations in the tape are made triangular in shape, so that, by shifting the tape transversely in the transmitter, the length of contact for dots and dashes may also be regulated. The apparatus for preparing the tape is fitted with two keys for the dot and dash respectively, and with suitable spacing keys. When a key is depressed, a contact is made which closes the circuit through the punching magnet; a contact on the armature lever of this magnet closes a relay circuit when a key has been depressed, and by means of pawl and ratchet mechanism causes a feed of the paper strip. The separate keys are arranged to give differential spacing. When the instrument is to be worked by persons ignorant of the code, the keys are depressed by magnets in circuits controlled by contacts operated from alphabetical keys. 8 claims.

26,656. "Improvements in and relating to electric accumulator plates." P. F. Ribbe. Dated November 15th, 1897. The plates or electrodes consist of a flat plate of lead with a thickened rim, and vertical rows of perforations covered on each side with celluloid strips, which are united to each other by celluloid solutions through the perforations. The strips have undercut edges which hold the active material in place. The whole is covered by thin plates of celluloid in which are many apertures. 1 claim.

26,657. "An improved device for guiding the carbons in electric arc lamps." R. W. L. Holsten and the Electrische Bogenlampenfabrik Naeck and Holsten Gesellschaft mit beschrankter Haftung. Dated November 15th, 1897. Relates to arc lamps.—The carbons in a focussing lamp are carried by movable holders and are guided near the arc by a thin cross bar and a mica plate secured on an enamelled reflecting disc, these parts being carried by clips adjustable on the side rods of the lamp. The arrangement permits thin carbons to be used. 1 claim.

26,659. "An improved automatic cut-out or short-circuiting device for electric arc lamps." R. W. L. Holsten and the Elektrische Bogenlampenfabrik Naeck and Holsten Gesellschaft mit beschrankter Haftung. Dated November 15th, 1897. Relates to means for short-circuiting a lamp should the arc in the lamp fail. The electro-magnet which regulates the arc acts on an armature fitted with a platinum contact and connected to one of the terminals. An electro-magnet and resistance are connected to the other terminal. In normal working, the contact does not touch the contact of the electro-magnet, but, should the arc fail, the armature is more strongly attracted and makes contact, so completing a circuit through the resistance. When the carbons once more approach, the current through the magnet is short-circuited and the armature falls away. 1 claim.

26,671. "Improvements in or relating to electrical indicating apparatus for use in hotels, restaurants, workshops, and for analogous purposes." A. J. Boult. (H. Montardier and L. Boudet, France.) Dated November 15th, 1897. Relates to an electric indicating apparatus or order telegraph for use in hotels, restaurants, workshops, &c. The transmitter is provided with two dials, one having interchangeable plates marked with the names of the articles, &c., which may be asked for, and the second being adapted to show the number of each article required. Two hands, fixed on the spindle and sleeve respectively, are capable of being moved over the dials, and the spindle and sleeve are each provided with a toothed wheel adapted to rotate the contact-making ratchet wheels through the pinions. The ratchet wheels each consist of a metal half and an insulating half, which are arranged so that the contact springs of the leads to the receiver alternately bear on a conducting part and an insulating part. The receiver is provided with two dials and hands corresponding to those of the transmitter, the hands being each operated by a clockwork mechanism, the escapement of which is controlled by an electro-magnet energised by the current from the transmitter. Only two connecting wires are employed, each transmitter and receiver having a local battery, the negative pole of which is connected, conveniently through a gas pipe or water pipe, to earth. In operation, the operator at the transmitter presses a call-knob, which completes the circuit of a drop-down annunciator at the receiver, indicating the number of the room from which the call is made, &c. The annunciator shutter, when it falls, completes the call-bell circuit. On receiving the call, the attendant at the receiver inserts a contact plug or jack in a socket corresponding to the number shown, so disconnecting the annunciator circuit, and, by pressing a push, makes the reply call. The operator at the transmitter then moves the hands over the dials until they point to the required indications, the hands of the receiver following step by step the movements of the hands of the transmitter. The hands of the receiver are re-set to zero by a bar, which disengages both escapement levers simultaneously, and so permits the movement of the hands until they are checked by a stop-finger at the zero point. 4 claims.

26,680. "Improvements in electric accumulators or storage batteries." A. Tribelhorn. Dated November 15th, 1897. The electrodes are made of a cup-like shape in order to form a receptacle for the electrolyte. The active material is spread on the upper and lower surfaces of the receptacle, or may be in the form of rods or bars projecting upwardly and downwardly from the receptacle. The electrodes are arranged in tiers as shown, insulators being placed between each pair of electrodes, and the electrodes may fit closely together so as to form a sealed battery provided with suitable gas exits. 1 claim.

26,682. "Improvements in electro-medical and exercising apparatus." W. A. Webb. Dated Nov. 15th, 1897. (Date applied for under Patents, &c., 1883, Act, Sec. 103, June 2nd, 1897, being date of application in United States.) Relates to a pair of dumb-bells, Indian clubs, &c., used in connection with an induction coil and a battery, for electro-medical and exercising apparatus. A dumb-bell connected by insulated wires to the induction coil having a contact-breaker, and enclosed in a casing which rests on the chest is shown. The insulated wires leading therefrom pass over the shoulders, and carry at their other ends, resting on the back, any suitable dry battery enclosed in a casing. The coil is arranged in an eccentrically-arranged recess of the casing having wires leading to the battery, and a vibrating contact-breaker in a recess closed by a sliding-cover. Each bell has a metallic tubular handle connected to hemispherical metal ends, the latter being connected together by a screwed rod passing through the whole bell. The handles are provided with binding-screws for connecting up the bells with the induction coil. Small spring bolts are arranged beneath slits or openings in the adjoining edges of the hemispheres, whereby metal discs or coins may be forced into the heads to increase the weight as required. 7 claims.

26,727. "Improvements in electric brakes for cars." O. J. Menzies and J. A. Bell. Dated November 17th, 1897. Relates to electric brakes.—An electro-magnet is secured to the axle upon which the armature is loosely mounted and connected by a chain to the pivoted lever for operating the brake beams. The electromagnet, which consists of a number of coils in series arranged around the hub, when energised attracts the armature and thus produces a resistance to the movement of the latter on the car axle, thereby winding up the chain and applying the brakes. 6 claims.

26,728. "Improvements in and connected with alternating electric current electric motors." W. L. Wise. (A. J. Churchward, United States.) Dated November 17th, 1897. Relates to the construction and mode of operation of a single-phase self-starting alternating-current motor, combining in one machine the principle of an alternating current synchronous motor, with that of the ordinary continuous current motor used for non-synchronous or starting purposes. The motor is arranged so as to operate first as a non-synchronous motor, and after attaining the requisite speed, it is converted by suitable switch mechanism into a synchronous motor. An application of the invention in its simplest form to a bipolar motor comprising an ordinary continuous current armature with its commutator, and a field magnet, the poles of which are each wound with a shunt coil and a series coil is shown. Upon the armature shaft are also mounted two slip rings and a rectifying commutator, and the various parts are connected as shown with two series of terminals, which in conjunction with a pivoted switch bar, carrying suitably disposed contact plates, enable the connections to be changed from those necessary for non-synchronous to those necessary for synchronous running. In starting the motor, the switch bar is depressed so as to close the contacts; the field circuit is now in series with the armature, and both carry an alternating current. When the motor has run up to synchronism, the bar is raised so as to close the contacts; the field circuit is again in series with the armature, but it is now supplied with a continuous current through the rectifying commutator; at the same time the shunt circuit is closed, and the motor runs as a synchronous motor. A self-induction coil, or a condenser, is arranged as a shunt across the brushes of the commutator so as to equalise the current in the field circuit. For efficiently starting the motor, a regulating coil wound on a circular core is placed across the mains. The switch bar may be operated by hand or it may be operated automatically by means of a centrifugal governor, and the switch arm of the regulating coil may be operated simultaneously by the same mechanism. Means are also provided for retaining the bar in either of its two positions and for automatically releasing it, by the action of the two electromagnets, when the motor attains the synchronous speed or falls below it. The lead of the commutator brushes may also be automatically varied by the switch mechanism, so as to avoid sparking. 18 claims.

26,732. "Improvement in or relating to systems of electrical distribution." L. Andrews. Dated November 17th, 1897. Relates to systems in which current is supplied from a central generating station to sub-stations or distributing plant, and consists in arranging magnetic cut-outs on the feeders, so that should one fail and the current be reversed, then that feeder would be cut out. An electro-magnet is arranged in series with the feeder to be controlled, and its pivoted armature is wound with a coil connected to the working circuit. In normal working, that is, as long as the feeder supplies energy to the system, the armature tends to rotate clockwise, but is prevented by a stop. In this position it supports the weighted arm of a switch. Should the feeder under abnormal conditions absorb energy, the armature rotates in the opposite direction and releases the arm. The construction of the cut-out is described in specification No. 3,496, A.D. 1898. 2 claims.

26,733. "Improvements in magnetic cut-out apparatus." L. Andrews. Dated November 17th, 1897. Relates to a magnetic cut-out for cutting out an outgoing lead should the generator fail. Generators connected in parallel to the conductors are shown, also a switch which is operated automatically to break the circuit should the generator fail, and be driven as a motor or otherwise. A field-magnet is in series with one of the leads, and its rotary armature core is provided with a shunt winding. The end of the armature is a catch supporting the weighted arm of the switch. Normally the armature tends to rotate clockwise, but is held by a stop. On reversal of the current it rotates in the opposite direction and releases the arm. 1 claim.

26,752. "Improvements in flexible conduits for electrical conductors." E. T. Greenfield. Dated November 16th, 1897. Flexible conduits are formed by alternating layers of rubber or other flexible insulating material strips. The inner layer forms a closed spiral, or may be a complete tube, while the outer layers form open spirals which break joint throughout. In the form shown the outer layer is corrugated centrally so as to force the underlying rubber between the metal spiral. In another form the inner metal spiral is concave in section and has a central row of projections, the outer layer being convex and having internal cross ridges to form a locking connection. The layers are attached by rubber, &c., cement, and the whole may be vulcanised as desired. 7 claims.

27,598. "Improvements in electrical fusible cut-outs." G. Byng. Dated November 24th, 1897. Electric cut-outs.—In order to minimise the dangers from arcing, the fuse wire is led through a chamber or compartment lined with a refractory material which will not volatise at the high temperature of the arc. The base, cover, &c., may be of china or the like, with suitable partitions covered or lined with plaster of Paris, cement, firechay, &c. In modifications, the fuse wire is led through a tube or handle suitably lined. 3 claims.

27,619. "Improvements in incandescent electric lamps." R. Nordmann. Dated November 24th, 1897. Incandescent lamps.—The body of a lamp consists partly of a lens attached by fusion. The filament is made of a sinuous form in a plane near the lens. 2 claims.

28,157. "An improved form of relay applicable to pneumatic or electric organs or to other apparatus." R. Hope-Jones. Dated November 30th, 1897. The invention relates to a form of relay applicable to organs and other apparatus where a movement started by hand is completed by electric or pneumatic agency. A wind chest containing air under pressure communicates by a port with a bellows, and by a second port with a second bellows. The ports are controlled by valves on a rod connected by a friction clamp with a key. On depressing the outer end of the key, the first port is opened to the atmosphere, and the second port to a chest. The remainder of the motion of the key is thus effected by the bellows. The movement is reversed by slightly raising the key. 5 claims.

28,159. "Means for use in lighting cars or carriages by electricity and for regulating the current for the same." S. Watkins. (American Railway Electric Light Company, United States.) Dated November 30th, 1897. The generator is carried on the axle of the car, and means are provided for automatically regulating the current and for maintaining its flow constant as to direction though the rotation of the armature be reversed. A bearing sleeve is also described for carrying the armature. The dynamo is enclosed in a casing, and is supported partly by the axle and partly from the undercarriage of the truck, a lug on the frame resting on a spring carried by the pendant. The current is regulated by varying a resistance in the field-magnet circuit, an arm being moved over the contact disc by a ratchet mechanism controlled by an electro-magnet in the main circuit. The coil has a movable core pivoted at the bottom to an arm and normally forced upwards by an adjustable spring. A shaft rotated by worm gearing from the armature carries a crank engaging with a fork on a rocking shaft carrying pawl fingers adapted to engage when in the proper position with one or other of the reversed ratchet-wheels on the shaft of which the contact arm is carried. When the current exceeds the limit, a core with its extension is drawn down, allowing a finger to engage a wheel which causes resistance to be put in the circuit. When, however, the current falls, the core rises under the action of the spring and one of the fingers come into play and cuts out resistance. In order to automatically reduce the action of the spring when the lights are in use, a magnet is included in the circuit, its armature being attached to a lever which is connected at one end to the spring. The current is kept constant as to direction in the external circuit by a rocking reversing switch, which is controlled by means of a sleeve having a helical groove in which works a stud connected to the switch arm. 9 claims.

28,242. "Improvements in or relating to negative plates for secondary batteries." P. J. K. Dujardin. Dated November 30th, 1897. Secondary batteries.—Relates to that class of battery in which the negative electrode is amalgamated zinc, cadmium, or the like, and consists in constructing that electrode so that the mercury shall not be liable to flow from the upper part of the electrode to the lower part. For this purpose the plate is made up of a number of separate strips of zinc or the like, which are suitably mounted and enamelled at their ends. The strips may be made of wire twisted into the form of cables. The electrode may consist of a single plate with a number of horizontal slots in it, and the strips may be twisted into a horizontal position. The electrodes may be made of woven wire fabric, or may be perforated or pitted. 3 claims.

28,246. "An improvement in safety electric fuses." H. C. Gover and W. Muller. Dated November 30th, 1897. The base is formed with slots adapted to receive sliding inverted T-pieces carrying the terminals to which the wires are secured. The wires pass in through holes and are secured by screws, and the fuse wire is threaded through a tunnel and secured by screws. Slots are cut in the screw thread, and communicate with a groove which is in communication with the exterior through openings. 3 claims.

THE INDUSTRIAL DEADLOCK.

ATTENTION has been drawn recently in these columns to the difficulties that beset the electrical industry in being unable to cope with the constant stream of orders that is flowing in. There are some philosophers who maintain that to have a plethora of orders is almost as bad as having none. Probably there is a certain amount of truth in the assertion, but there is this marked difference, when a man has no orders he may be credited with doing his best, but when his shops are so full that he cannot keep up to time he receives the obloquy of all. It must be admitted that the manufacturers of electrical apparatus have met with most generous consideration at the hands of both consulting engineers and municipalities. Probably this indulgence arises to some extent from the difficulty in enforcing penalties, but whatever there may be in this, there has been no disposition to harass manufacturers in spite of their delinquencies.

If orders remain unexecuted a few weeks beyond the specified period it may be highly inconvenient, but when weeks pass into months and occasionally into years before electrical plant is delivered, the matter goes beyond the bounds of reason. Yet it is well known that makers of electrical machinery, in one or two cases, have been over 18 months behindhand with their machines. These are probably the worst instances, but they show in the clearest possible manner either that some shops are overrating their capacity, or that there is some strikingly bad management. In the comparatively early days of the electrical industry, when manufacturing concerns rarely or never paid dividends, it was urged, possibly with some reason, that extravagant prices of patents, with the resultant over-capitalisation, were responsible for the inability to make profits. But nowadays all that is changed; the electrical industry is practically free from patents that touch the main features of electrical supply, and the chief effects of over-capitalisation have been swept away. How is it, then, with the prospect of fair profits, with the accumulated experience of years, and the employment of the most highly skilled labour, that so many English manufacturers are unable to keep their promises? To some extent the matter is capable of explanation. Up to a certain point the demand for electrical machinery was a gradually increasing one, and manufacturers were able to complete contracts somewhere near the specified time. So far as we are aware, however, there appeared to be little disposition on the part of the managers of workshops to look a little ahead, and make some provision for the boom in electrical plant that was bound to come; so long as the work in hand was completed the morrow might take care of itself. We are not for a moment suggesting that every manufacturer in the country was imbued with this policy of *laissez faire*, but we do not exaggerate when we say that the great majority have acted on this principle. What is the result: the boom in electrical enterprise has come and filled the English shops to overflowing, and the orders have followed so rapidly on

Digitized by Google

one another that the energy of a portion of the staff has been devoted to carrying out extensions of the workshops. Orders for plant have been taken with a sort of blind faith that everything will come right in the end, and probably it will, but in the meantime there is a reckoning to be paid. It is never pleasant to turn work away from one's doors, but assuming one has a clear knowledge of the possible output of a shop, it seems the height of folly to endeavour to double it. A harsh term would be applied to a person who sought to put more than a pint into a pint pot, yet that is precisely what the home manufacturer has been attempting. There may have been an idea that when the large towns had put down electrical machinery there would be very little more required; but the systems at present in existence have done little more than merely demonstrate the commercial possibilities of electric lighting and power supply. Before electricity is supplied to the average householder enormous plants will need to be erected.

Just when electric lighting had become established on a sound commercial basis, municipalities and tramway authorities became convinced of the economy of electricity when applied to tramways. But the demand for tramway plant and materials that followed has found our English works totally unprepared to meet it. Our American friends very readily perceived our state of unpreparedness, and they have quickly filled the breach. The consequence is that some of the very best orders for electrical machinery are to-day crossing the Atlantic. We are quite aware that the strength of the Americans in this country may be exaggerated. If the newspaper reports are to be relied on, the chairman of the Midland Railway Company has declared that the engines which have been recently supplied by the Americans were not nearly so good as those constructed at home. There are authorities in this country who maintain that many of the engines supplied from America for tramway work are inferior to those of English manufacture; but whatever truth there may be in that opinion, it is obvious that if American engines can be relied upon to perform fairly satisfactorily, they will, by reason of quick delivery, continue to be used to a considerable extent.

Although we have pointed out the delay that has arisen in the delivery of a good deal of electrical plant, we readily enough admit that the majority of firms will not at the present moment accept orders for machinery under a somewhat protracted period. That must necessarily divert orders either to America or to the Continent, but regrettable though that may be from a merely insular point of view, it is, from the standpoint of the electrical industry, infinitely to be preferred to keeping customers waiting for long periods.

Here and there workshops spring up, and for a time, at least, their chief advertisement is "early delivery," and apparently on the strength of that alone they secure a large number of orders, but their shops are soon overstocked with work, and very speedily they join the ranks of the great majority who are too busy to promise delivery under six or nine months. The cry of too much work is an irritating one, and it is doubtful if the manufacturers are doing any good to themselves by constantly repeating it. It may give rise to the reflection among men that either English works are limited in their capacity, or they lack organisation. In some industries it is astonishing how the supply keeps pace with the demand; we take it that neither Whiteley's nor Lipton's would ever have succeeded if they had become too busy. A growing demand needs courage and a long head in order that it may be properly met.

It is almost unnecessary at the moment to enlarge upon the superior position of the American firms to English houses in their ability to deliver plant quickly. At different times we have endeavoured to analyse the causes that account for these marked differences between the American and English electrical industry, but whatever may be the true reasons, the effects are occasionally brought before us in the most forcible manner. The demand for electric motors must be already a very large one, but when electric driving becomes properly recognised, both in large and small factories, an enormous number of motors will be required. With the present limited use, however, English manufacturers cannot supply them under some months. Quite recently a well-known engineer endeavoured to obtain a considerable number of electric motors for a client, but it was impossible to secure them within a reasonable period in this country; yet within three weeks an American firm was able to deliver the complete set of 40 of varying horse-powers. English manufacturers would have designed and made them specially, the American firm took them from stock.

American Workshops in England.

It will be a matter of great interest to watch the developments of American enterprise in establishing workshops in England. If the Westinghouse Company at their new works are likely to employ 5,000 men as anticipated, the question arises, Where are these men to come from? If skilled men are wanted they will have to be drawn by superior inducements from other employment. These being obtained, and working, we may suppose, equal hours with men in other shops—they will hardly be allowed to work shorter hours by an American management, accustomed to the long hours of America—will there be any trouble with the trades unions when the American method of multiple tools is, as it will be, insisted upon? Will the now discredited Amalgamated Society of Engineers make a fight over the employment of floor-labourers to attend to automatic machine tools? We feel much inclined to welcome the American company in establishing its works in England. English wages are not much less than American, in many cases they are higher. Per unit of output under the paralysing influences which have crippled English practice, the wages cost is distinctly higher all round. Assuming that the American company can effect no good with its workers, it will be a very simple matter to charter a large steamer and land 1,000 men at once from New York at the works on the Ship Canal at Manchester. There are plenty of workmen in America who would, if required, make the change. They might not at first like the change, for an American is intensely conservative in his habits of life, and does not mind sleeping in a windowless cell if he can only get green corn to eat. But he would in time find that climatically and otherwise he was better off here than at home. Bar the lack of transit facilities, England is a pleasanter country to live in than America. We may take it that a sufficient force of American workmen could be permanently maintained at the new works. In receipt of good wages and well housed no outcry could be raised against them, and they would be safe from outrage in a way they would not be in America. We should then have the spectacle of the new works underselling most competitors, simply because of its cheap output. This could scarcely go on; the closing of works unable to compete would follow. It might be necessary to do this before the trades unions recognised the folly of opposing new methods any longer. The new works would, however, be a centre of influence, from which surely better ideas would radiate. Secure against the tyranny of a works' stores, too common in America, by the protection of our Truck Act, and generally under the protection of English law, we do not see that the American works could become an evil. The methods of the Carnegie Company would be impossible, and Pinkerton men to shoot at sight could not be employed. On the whole, therefore, a healthy competitive influence may be anticipated. It must strike the more thoughtful of trades unionists that one consequence of their efforts to defeat modern methods of production should have been the planting of a large works right in our midst to carry out such methods. While we have assumed the possibility of a struggle, we scarcely think this will arise. Those behind the scenes know that many English workshops have been enabled to make great changes since the strike of 1897, and probably the new works will simply serve as a stimulus all round, and hasten the adoption of better methods. There is room for more manufacturing in England; at present it is impossible to obtain anything in decent time. Steam engines, cars, motors, boilers and all classes of engineering work can only be obtained in reasonably short period from America. It is quite time this was changed.

A "FIN-DE-SIECLE" MACHINE SHOP.

By FRED. BATHURST, A.M.I.E.E.

(*Concluded from page* 279.)

FIG. 10 shows a most compact and important machine, being a simple combination which avoids a separate pumping

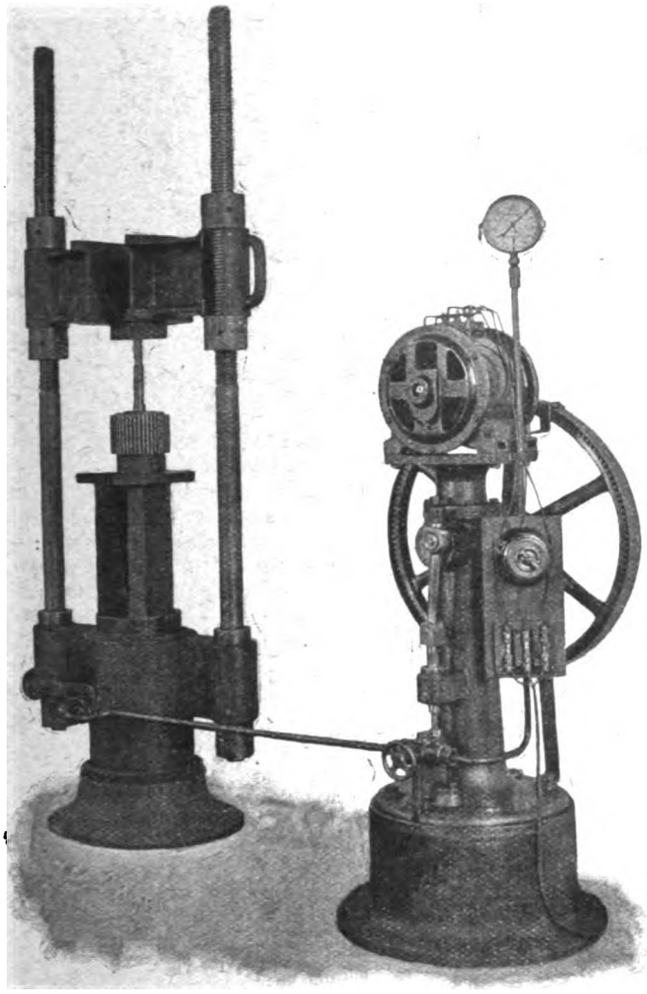

FIG. 10.

engine and its unnecessary gearing. It represents a convenient design of vertical type hydraulic press for compressing small armature bodies, commutators, &c.

A 1½ H P. motor is single geared to a small single-acting pump, the pipe from which connects to the plunger chamber of the press. In this particular press a total pressure of 15 to 20 tons can be obtained, complete control being maintained by the indication given on the recording gauge seen at the side of the pump, and which indicates up to 2,000 lbs. per square inch. With the specially constructed cross head fitted to this press, it will be seen that the laminated armature discs for a drum-wound armature body can be quickly pressed together, or the machine is equally suited for pressing a shaft into the carrying spider for a gramme ring body.

Fig. 11 shows an excellently compact and well designed field magnet spool winding machine. This special machine is driven directly by a 1 H P. motor arranged on a sliding base and controlled by a rack and pinion. The winding shaft is driven through a train of gears from a flat circular friction plate. Any speed of winding can be obtained by moving the motor in or out along its base plate, so that the pulley on its armature shaft drives against the outer or inner periphery of the friction plate, according to the relative position of the motor. The machine is fitted with a wire-holding or tension gear, and the usual train-wheel counter for registering the number of turns of wire wound on to the spool is provided. Its approximate cost is about £70.

Incidentally this combination shows the simplicity of the application of a separate motor to a machine requiring comparatively small power, and which may have to be run at varying speeds and yet be started and stopped at pleasure. The field magnet winding machines usually employed in dynamo shops are designed on the lathe principle, and have the loose pulley running continuously, but inasmuch as considerable time must be spent in adjusting the insulation of each spool, and spools when filled with wire have to be changed and replaced by others, it has been found to effect a considerable daily saving in the main engine driving power to adopt winding machines of this type.

Fig. 12 is interesting as an illustration, in that it shows the size of the tools that will have to be provided in shops laid out for the manufacture of the multipolar generators, which must ultimately take the place of the comparatively small machines at present employed in English station practice. This represents one of the large lathes specially constructed in the Kolben shops for the purpose of tackling pieces of work up to 80 feet in diameter. The work shown in the illustration is a 64-pole revolving type magnet wheel, weighing over 55,000 lbs. The pole faces are being trued off, so that the magnet will set accurately within its correspondingly immense and stationary armature ring. The main construction required in this lathe is its solid bed-plate, with the necessary well-hole and adjustable bearings, capable of accommodating removable plummer blocks for carrying the bearings of any sized shaft. The tool head is comparatively only an insignificant part. The work is revolved on its own shaft by being belt-driven from a 8 H P. motor, which in order not to further encroach upon the floor space occupied by the bed-plate, is bolted to the side of the shop wall well up above the machine. The turner has complete control of the operation of this lathe by means of the motor switch and loose belt levers arranged near at hand.

Fig. 13 shows a small portion of the armature-winding department, and is interesting in that it shows side by side the "ancient and modern" in armature construction. On the left, supported on their wooden rests (easily recognisable

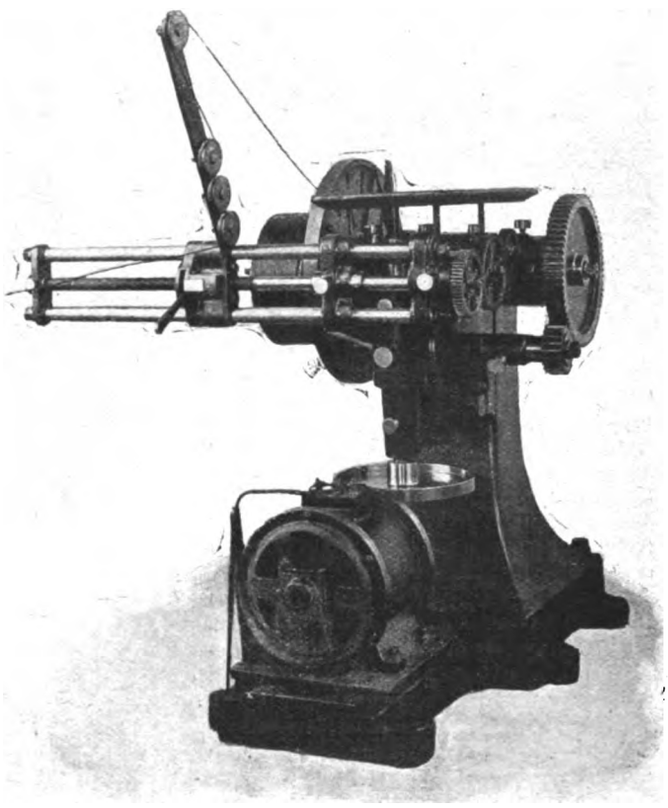

FIG 11.

from their compact and solid form and comparatively small diameter) can be seen "gramme" ring, and "drum" wound armature for machines of varying size, from 25 KW. to 200 KW. On the right can be seen the two huge semi-circular shaped castings, which are ultimately to form the

Digitized by Google

stationary armature of a 1,000-H.P. three-phase generator. This side-by-side comparison sufficiently accentuates the kind of change that may have to be encountered when a dynamo shop proceeds from the manufacture of small to that

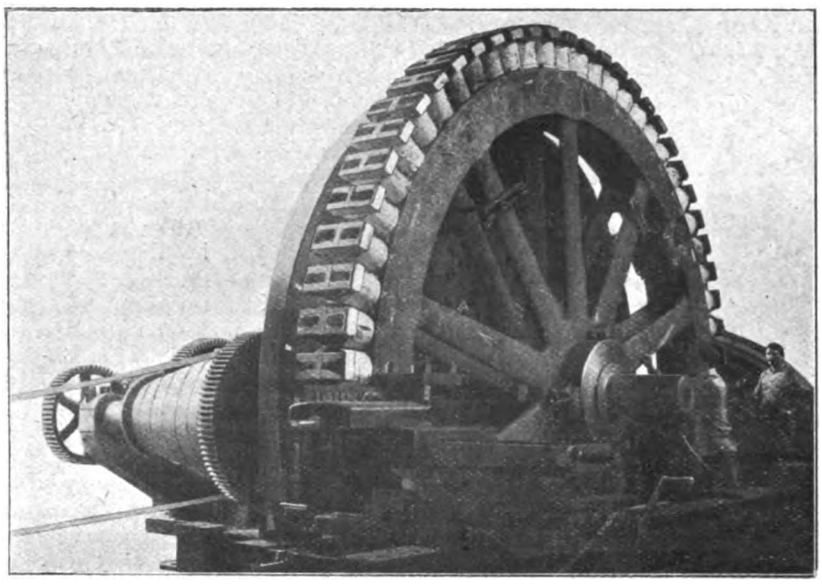

Fig. 12.

of large generators. In the distance will be seen the assemblage of two large armature body rings, one arranged inside the other; and further in the distance, on the left, the erection of the wrought-iron frame of a large switchboard.

Overhead may be seen the bottom of the controlling cage and the hanging chain of the travelling crane that runs over this section of the shop. Every modern shop designed to handle large castings will, of course, be equipped with electric travelling cranes which can run the whole length of the shop and work over a system of shop tramway rails, so that the castings can easily be passed on from one shop to another. Although the Kolben Factory consists of only two large main buildings, one of which is divided centrally, accommodation is found for no fewer than *six* large travelling cranes, two each of 5, 12, and 15 tons, having spans of 30 and 40 feet respectively.

Fig. 14, although not actually photographed in the Kolben shops, shows a 50-ton three-phase motor crane, made by this firm for a neighbouring locomotive works, with double travelling trolleys, so as to be capable of handling small locomotives *en bloc*. In this case the longitudinal motion is given by a 12-H.P. motor, the travel of the trolley by 8-H P. motors, and the lifting by 20-H P. three-phase motors.

The application of three-phase current to crane work might, at first sight, be criticised on account of extra complication in respect to wiring connections, but these practical examples show convincingly that all difficulty is easily avoided. The three main trolley wires required along the shop are easily provided for, and although 11 contact strips or wires must be provided on the crane girder itself, the greater simplicity and compactness of the regulating boxes more than counterbalances any objections which might be raised as to complicated connections.

In addition to the main shop cranes, the side bays of the shop, which cannot be covered by the travelling cranes, and in which the smaller kinds of tools are placed, are provided with separate hand-power cranes, either travelling or stationary, as demanded by the nature of the work to be handled. The upper parts of some of the side bays are made to provide extra working galleries in which the small detail parts are assembled or finished, and switch or other small work made. One finds in these cases that the labour of handling material is reduced to a minimum by the provision of electric elevators to convey material from the shop floor to the upper level.

Fig. 15 shows the complete elevator equipment. The machines are designed to raise an ordinary flat platform cage, loaded up to 1,100 lbs., at a speed of 60 feet per minute.

The winding drum is driven by a 8-H.P. three-phase motor, which runs at 1,440 revolutions. The gearing arrangement adopted was originated by the Kolben Works. A specially made phosphor bronze screw is arranged on the motor shaft, so that it drives on to a hardened and polished steel worm wheel on the drum shaft; by this means a direct reduction of 1 to 40 is obtained without other gear apparatus, and a very compact and economical combination effected. This elevator runs without any attention, being quite automatic in its action; the movement of the starting rope raises the brake on the motor shaft, and operates the three-contact armature resistance controller at the same time, so that the cage starts slowly and smoothly.

The complete motor and winding drum equipment weighs about 600 lbs., and costs approximately £120. The overall dimensions are:—Height, 2 feet 2 inches; width, 2 feet 10 inches; length, 3 feet 2 inches.

The liberal use of cranes and portable power apparatus in this shop not only reacts favourably upon the time taken in finishing and assembling the complete machines by almost entirely superseding the "gangs of labourers" ordinarily required in busy shops to move the heavy castings from

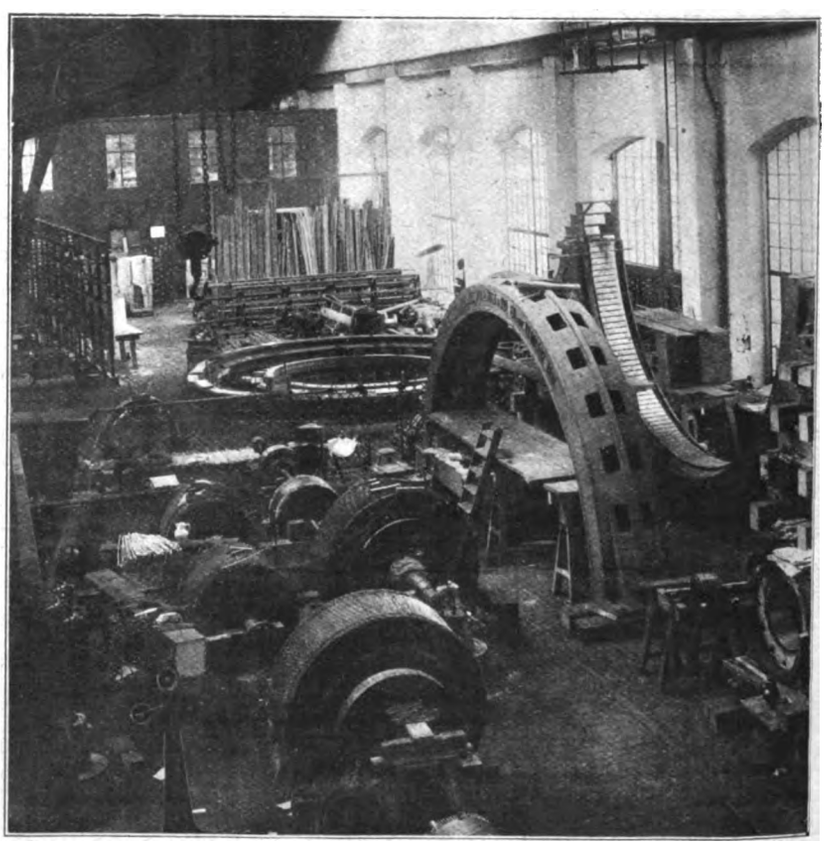

Fig. 13.

place to place, but materially reduces the usual standing charges of shop production. In fact, throughout the whole of the shop every possible economy in time and labour seems to have been considered, for on passing from the machine shop to the foundry, not only is it found that

Digitized by Google

the pig iron and coke is served to the cupolas by elevators of the type shown in fig. 15, and the draught furnaces maintained by means of 20-H P. three-phase motors driving the air-blowers, but recognition has been taken of the fact that the foundry is usually behind time in keeping up with the production of the machine shop. When working upon such large castings, it is obvious that a comparatively small

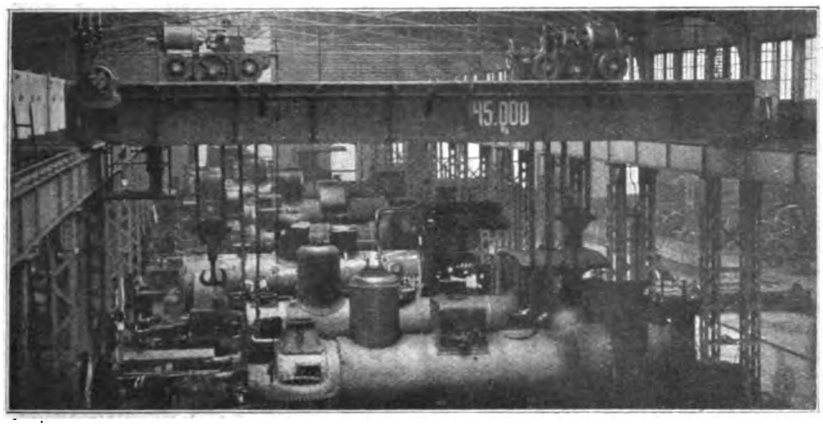

FIG. 14.

number of patterns will occupy a large amount of floor space for moulding purposes, and inasmuch as these large moulds, even when formed, may take many hours and even days to properly *dry out*, delays may, under ordinary conditions, ensue. The output of the Kolben Factory has practically been doubled without any increase of floor area by laying around it a comprehensive system of piping, through which a current of air can be forced to any desired part. If a large mould has to be finished as quickly as possible a portable coke oven is placed about it, and a flexible pipe connection made from the air pressure system, so that a steady current of warm air can be passed into any part of the mould as required. In this way moulds of awkward shapes and sizes can be dried out far more evenly and rapidly than when left for the usual open air drying, and the floor space accommodation is utilised to its utmost capacity, the same spot often being used three or four times over in the time originally required, as when the moulder, leaving the drying to Dame Nature, could take "his own good time" and regulate the floor output to suit his own particular view or fancy.

As the main object of this article has been to describe a series of important labour-saving processes and tools, the matter descriptive of the factory itself has so far been kept in the background, that the casual reader interested in shop practice may probably have formed the opinion that the tools illustrated could only be found employed in one of the oldest and largest machine shops. In truth, however, it is scarcely four years since the acre of ground upon which these shops stand was first broken, but so rapidly has demand followed upon ability to turn out the highest class of work, that to-day we find 300 skilled Bohemians busily employed, and working in day and night shifts, with as much method and order as if the whole establishment were practically one huge machine. The transformers made vary in size from 100 watts (used for voltmeters and switchboards) to 500 KW., and the motors and generators from ½ H.P. to 2,000 H.P., the bulk of the work being the larger sized units required for important town lighting and power transmission plants; hoists, cranes, railway motors, switchboard equipments, all come as extra grist to this electrical mill. The turnout increasing proportionately with the growth of the works may well be envied, the present year's output alone in transformers, generators, and dynamos of all sizes being estimated in the aggregate at 50,000 KW. total capacity.

The power transmission plant of the shop is also unique in its way, as it illustrates how much can be effected from small resources, provided the guiding hand has the requisite knowledge and experience.

Whereas it would be thought that a factory employing so many machines must require a main steam plant of considerable horse-power, one is surprised to find that the whole factory is driven from a 120-H.P. engine. Two Lancashire boilers of 120 H.P. and 60 H.P. each respectively (180 H.P. total) supply steam at 120 lbs. pressure, which is then passed through a superheater (utilising the heat of the boiler flues) and raised from 170° C. to 270° C., at which temperature it is passed into the parallel cylinders of the compound engine. By such superheating the condensation losses are kept very low, and a very high steam efficiency obtained. The exhaust steam warms the shop in winter, or gives a hot water supply for the boilers.

Both boilers and engines are housed side by side in a building 40 feet × 40 feet, the actual size of the engine room being only 40 feet × 16 feet, which explains the difficulty of obtaining a better general view of its arrangement, than that shown in fig. 16.

The engine is belted directly to a 120 H P. three-phase current generator of 91 per cent. efficiency (50 cycles), 220 volts, and provided with its own fixed exciter. Some 50 electric motors, having capacity from ¼ to 20 H.P., are employed in the shops, the majority being operated at 200 volts. Owing to the comparatively small size of motors employed, and their consequent high speed and the difficulty of gearing them down, the shop shafting is run at 270 revolutions per minute instead of about 180 revolutions, the usual standard speed for ordinary machine shop practice. This higher speed is, of course, advantageous and quite possible under the conditions of lighter and shorter shafting runs.

The shop wiring is arranged with an earthed neutral, so as to prevent the possibility of the workmen receiving shocks, and to allow light to be supplied on the single phase from either of the three wires at 125 volts. The lighting can be taken

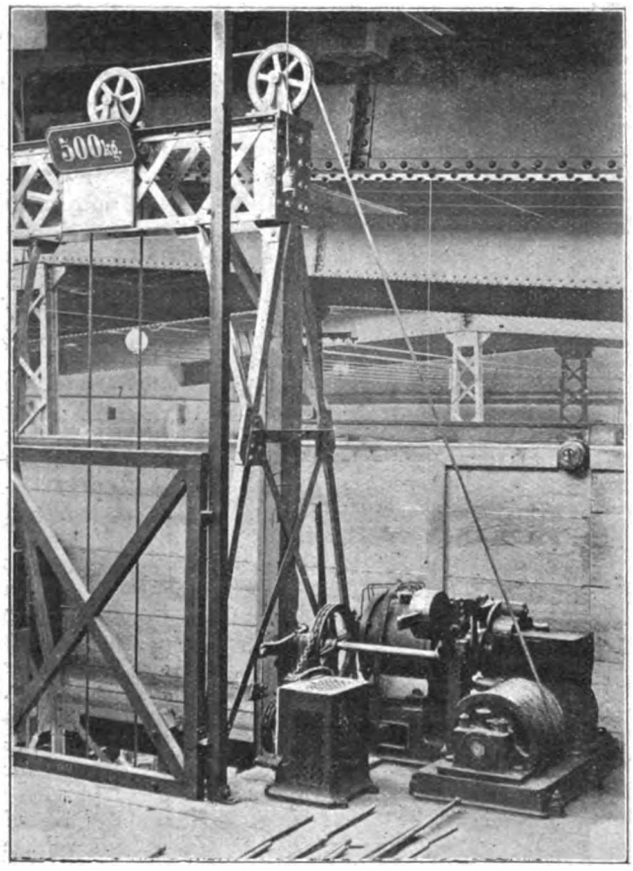

FIG. 15.

direct from the power wires throughout the shop, or, if desired, from a set of accumulator cells.

The accumulator is charged from the three-phase generator by the intervention of a rectifier. This rectifier of 6 KW. capacity, although only in an experimental form, affords a simple and economical method of changing a three-phase alternating into a continuous current. It consists simply of

Digitized by Google

series of contacts and collector rings, arranged on a shaft, which is driven by a ½-H.P. three-phase synchronous motor, running off the main generator. A three-phase stationary transformer is connected to the mains from the generator, and the sections of the coils connected to contact rings on the shaft. These contact rings are again connected to a suitable commutator, so that the three-phase current from the transformers is collected as continuous current. This 6-KW. rectifier occupies less than 15 cubic feet of space, and the loss in the transformation does not exceed 5 per cent. Excessive sparking and other troubles would, of course, follow in large

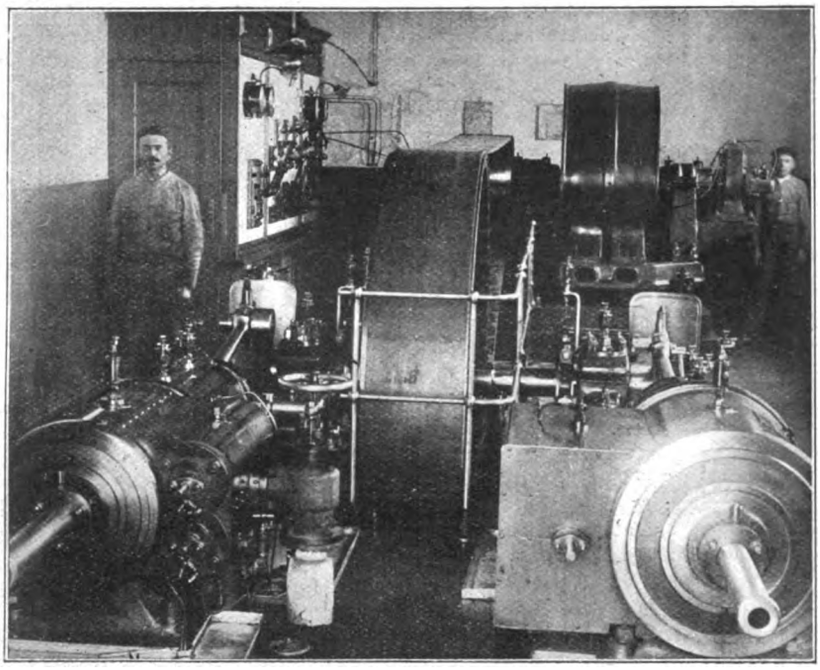

FIG. 16.

sizes, but Herr E. Kolben considers that it may eventually compete with the standard type of motor-transformer (three-phase to continuous current, with a loss of 8—15 per cent.) for capacities less than 30 KW. This suggestion has already been made by Mons. Le Blanc, of Paris, but does not seem to have been properly worked out. Mention is made of this apparatus, as it forms a very cheap and effective means of providing for an auxiliary accumulator for lighting and other purposes in connection with three-phase power plants.

A corner of the small engine room is allotted to the switchboard, which contains the ampere and voltmeter necessary for controlling the large generators, and switching out the feeder, supplying the current for power to the various shop circuits. The engine room arrangements are thus relatively as small and compact, as the number of tools and appliances provided for is large.

In connection with the utilisation of three-phase current in this factory, and looking to the fact that at last in England we hear of some important three-phase plants being projected, notably in Manchester for its lighting, and in South Staffordshire for power (this latter scheme proposing to instal two 1,000-KW. and four 2,000-KW. generators), it may be of interest to mention that the Kolben Works are already well advanced with the manufacture of the three-phase generators, and suitable motor transformers for the first instalment of a 15,000 H.P. three-phase plant for the city of Prague. The units in hand are five of 1,000 H P. and five of 2,000 H P. The high voltage distribution is to be effected at a pressure of 3,000 volts, and motor-transformers of 700 H.P. (or 450 KW. each) 240 revolutions, will re-deliver the electrical energy as continuous current at 600 volts. The main object of the scheme is to supply and extend the present electric street railway system in the town of Prague.

Comparisons are proverbially odious, but may not the consideration of this work undertaken by a *single* town as the outcome of its *immediate* necessities, lead us to ask how it is that a Continental town *only fairly* prominent in reputation and commerce, can give the lead to the whole of England in electrical supply undertakings of this nature?

Whatever schemes English electricians may have in contemplation for the *future*, the shortest visit to the Continent must convince them that we lag far behind in respect to street-railway and power-installation practice. From the fact that we have relatively so many large towns cooped up within our little island, in the matter of electric lighting, we may possibly find ground for debate; but here, again, a fair judgment must admit that we are also behind. The "slow and sure" and "wait till it comes along" policy that forms the keynote of English electrical development may, it is true, be best in the *long* run, but with Continental examples of electrical enterprise of all kinds before us, surely it is time that a little more "initiative" and "go" should be instilled into our "authorities and rulers," "professors," and "consulting engineers," lest in the competitive race we are now running, the idea that we are "already too old and fossilised" should become too deeply rooted, and even impossible to eradicate?

This article, however, must not become controversial, being intended merely to serve as an index for our dynamo manufacturers, as to the kind of shop practice that prevails in the "more progressive" Continental factories.

Conclusion.— Enough has, it is hoped, been said to show that throughout the practice of this factory such advantage has been taken of the most up-to-date ideas and methods of manufacturing as to justify the heading under which it has been introduced.

NOTES ON THE CAREER OF EMIL KOLBEN.

He passed through the ordinary Bohemian school course and entered a technical college to undergo an engineering training.

In his holidays, particularly the long summer vacations, he used to enter the neighbouring factories working as an ordinary hand. After serving in an engineering works near Prague for a short time, he decided, in 1886, to go to the U.S.A., and there entered the drawing office of the Edison Machine Works, in Schenectady, N.Y. He made rapid progress as a draughtsman designer, and became head man. He then set himself to work out the designs for the improved Edison bipolar machine with the shortened magnetic circuit, carrying out at the Edison Works what was proposed in England by Dr. John Hopkinson.

It was the thoroughness with which these old-type machines were re-designed that made it possible for the Edison bipolar machines to gain the reputation for reliability and solidity that they hold in America even to-day. From head designer Mr. E. Kolben became chief engineer, the Edison Works having grown during these few years from three workshops employing 300 men to over a dozen shops employing 1,500 workmen.

In 1891 Herr Kolben returned to Europe on a tour of inspection, and in order to make a report as to European practice. This revived in him the love of his native country, and he returned to the States as a married man, and with a predetermination to exchange the haste and bustle of American workshops for the more even and steady going progress of the European. Within a year he came back to take up the position of electrical engineer to the Oerlikon Works in Switzerland, just then vacated by Mr. C. E. L. Brown, now of the Brown-Boveri Works. At Oerlikon, Mr. E. Kolben again showed his aptitude for dynamo design by completing and putting into standard shape a complete range of three-phase motors, and working out to practical and commercial success several important three-phase and other power transmission plants, besides finding a sphere of activity in the introduction into Europe of his American street railway experience. In these early days of commercial power transmission work, Mr. Kolben's name was well known to the technical press for his contributions and notes on dynamo

Digitized by Google

machinery designing, and it is not too much to say that his paper "On the Best Periodicity," published in the *Electrotechnischen Zeitschrift*, in 1894, led to the general adoption of 50 cycles as the standard for three-phase apparatus. During his sojourn in Switzerland, Mr. Kolben had every opportunity for indulging his passion for recreation in the shape of mountaineering, and with Mr. E. Huber (proprietor of the Oerlikon Works) as an experienced companion, many difficult and so-thought inaccessible peaks in the neighbouring Alps were assailed and conquered. Whether, however, it was due to Mr. Kolben's love for the hills and heights of his own native country, or "the homing" of his Bohemian nature, in 1896 he decided to return to Prague, the town of his birth, and start there as an electrical manufacturer in his own name. He evidently chose the proper moment, for to-day we find Austrian manufacturing activities rapidly developing all along the line, and to judge from what has been accomplished in this factory within so few years, Mr. Kolben will have the satisfaction and reputation of having initiated an industry which will grow to be one of the not least important. Mr. Kolben is quite a young man—not yet out of his "thirties"—and has all the talent, energy, and experience necessary to develop his factory, so that, retaining his good health, he ought long to enjoy its fruits and reward.

INDISPENSABLE ACCESSORIES OF ELECTRIC TRACTION.

By HENRY E. P. COTTRELL, A.M.I.C.E.

(*Continued from page* 262.)

Fig. 72 shows the connections of "Ajax" lightning arrester for isolated plant, and fig. 73 shows the connections

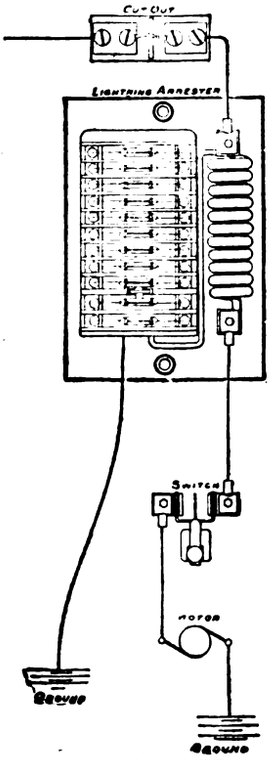

Fig. 72.—Connections of "Ajax" Lightning Arrester for Isolated Plant.

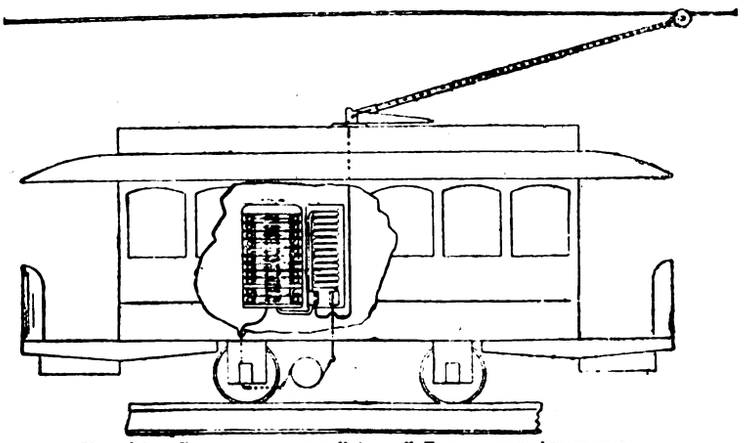

Fig. 73.—Connections of "Ajax" Lightning Arrester for Motor Car.

for a motor car. These should have appeared with last week's section of this article.

Trolleys.

In this country the type of car generally in use is the double-decked car, which is a legacy bequeathed from the stage coach through the omnibus and the horse tramcar to the electric tramcar. It is problematical whether this double-decked car is an unmixed benefit, but certain it is that to our eyes the single-decked car would look as strange as the double-decked variety does to American and Continental eyes. The form of swivelling trolley suited to and used for the single-decked variety is not suitable for cars having seats on the roof, and a special type has had to be evolved to meet the requirements of the latter. The trolley pole, instead of starting from the roof of the car, has had to be raised on a standard of sufficient height to prevent it and all moving parts from interfering with passengers. The chief desiderata in a trolley to ensure satisfactory working are the following:—

1. The head must be of a form having no angles or projections save the edges of sheave slot, in which the wire can catch and prevent the head from being hitched readily into position when the trolley has left the wire. It must be fixed so as to swivel freely at right angles to the wire, and it must be completely insulated from the trolley arm by a non-conducting sleeve.

2. The sheave must be of the "V" groove type fitted with non-heating (graphite) bushings, and mounted so that its axis is on a level with or below the end of the trolley arm, and in this way lessen the possibility of the sheave striking a span wire or bracket arm. It must be provided with ribs to hold the flanges in position after they are cut or worn through, and thus prevent the disabling of the car before the sheave can be replaced.

3. The trolley arm must be tapered throughout its length and reinforced at the butt, and it must be insulated at the carrying socket by insulating material of the nature of mica. It must be supported by outside springs fixed, so that the pull shall be as near as possible at right angles to the arm when the latter is inclined at its normal angle.

4. The springs must be arranged so as to exert a pull which shall maintain a pressure of 18 lbs. between the trolley sheave and the overhead conductor; this pressure remaining approximately constant while the arm moves through an angle of 30° on either side of its normal position; the tension of the springs being susceptible, however, of instant release or adjustment.

5. The socket for carrying the arm should be of malleable cast-iron, mounted on a pivot, and fitted with an adjustable stop to prevent the super-elevation of the trolley head, and should be pivoted on a malleable iron swivelling sleeve.

6. The sleeve carrying the arm socket should rotate on two sets of ball bearings round a steel tube socketed in the standard, a complete revolution being prevented by a stop.

7. The standard in which the steel tube is fixed should be an annealed steel casting, the base being arranged so as to be fixed on to the car roof by coach screws.

8. The cable should be run straight through from the head to the heavily insulated connection box in the standard where the motor leads end, and be so arranged as not to twist or chafe; its connection with the head should be easily accessible, and its insulation throughout should be as perfect as possible.

The accompanying figure, 74, shows a recent type of trolley (Dawson's patent) which complies with all the requirements above mentioned, and whose use renders it easy to work a road where the trolley wire is horizontally 8 feet to 10 feet or

Digitized by Google

more distant from the side of the car, as it instantly follows any variations in the line of the trolley wire from that of the track. It greatly facilitates construction, decreases the number of poles, and diminishes the necessity for span wires.

Trolley Pole Catcher and Reel.

The accompanying figure (No. 75) shows an indispensable adjunct to a satisfactory trolley. From one cause or another trolley sheaves are bound occasionally to leave the wire, and the long bamboo fishing rod with its hooked end is a fruitful source of delay and expense, besides being awkward and unsightly. This adjunct consists of an enclosed reel fixed to the dashboard, or any other convenient part of the car where it is readily accessible to motorman or conductor, on which a cord attached to the trolley head is wound. The movement of the reel is regulated by a coiled clock spring, which, as long as the trolley sheave is running on the wire, instantly takes up the slack rope or pays it out to meet the inequalities of the overhead conductors. Immediately the sheave leaves the wire and the pole jerks upwards under the influence of the springs, the jerk brings a device resembling a centrifugal governor

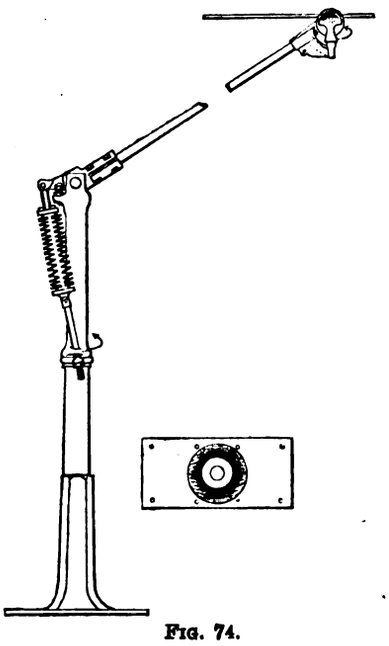

Fig. 74.

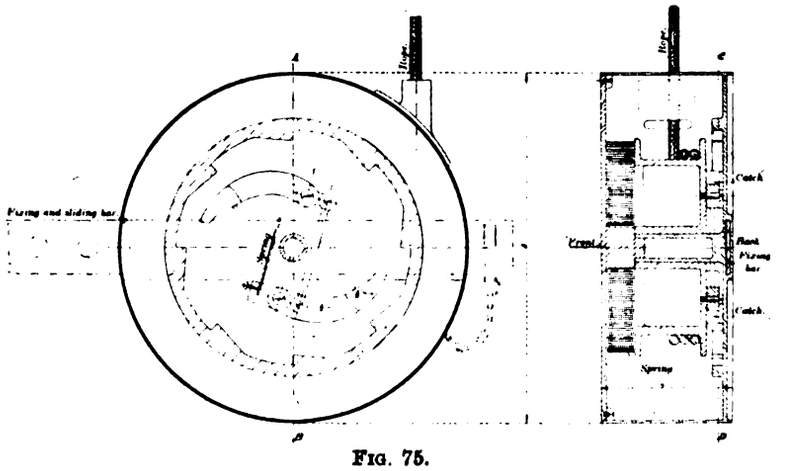

Fig. 75.

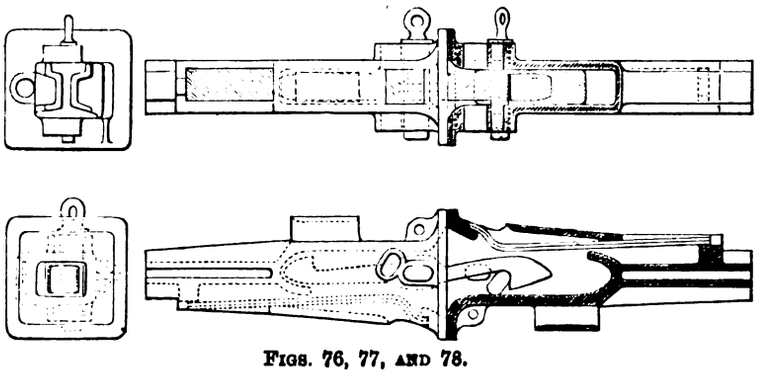


Figs. 76, 77, and 78.

into operation, which at once catches the rope and securely holds the pole until it is released by the conductor. The catching of the pole and the holding of it in position presents the double advantage of preventing wear and tear and injury to the wire, and of permitting the adjustment of the spring pull on the trolley pole to either a higher or a lower standard than the one which is imperative where no such adjunct is used. This device is also the invention of Messrs. R. W. Blackwell & Co.

Couplings.

Automatic couplings, or, as our American cousins prefer to style them, "couplers," have been very much in the air of late in connection with goods waggons in the United Kingdom. The authorities of the Board of Trade have at last realised that their adoption will diminish the rate of mortality among long-suffering railway servants in a way no other innovation could effect. Many excellent patents and devices have been known, and to a certain limited extent, used, for the purpose of automatically coupling up railway carriages and waggons in the United Kingdom for years past, but have mostly languished or practically died a natural death from lack of the support of railway companies and waggon owners, which nothing short of the unanimous insistance of their employés or of the Board of Trade could have brought about. Fortunately, in the case of electric traction, no such vested reluctance exists, and the adoption of automatic couplings is more or less assumed as a matter of course on this side of the Atlantic just as it is on the other side. What is required of an efficient automatic coupling is that it shall be—1st, perfectly automatic; 2nd, absolutely reliable; 3rd, impossible to get out of order; 4th, capable of coupling cars so solidly together so as to ensure perfectly smooth running, free from all jerking motion under all conditions of service; 5th, capable of coupling and uncoupling readily with the least possible longitudinal motion of the car; 6th, capable of use without alteration with any type of non-automatic coupling in general use; 7th, simple in construction and lasting in details. The first requirement entails the introduction of springs in the heads of the couplers, and requirement No. 5 demands that they shall be so set that they will engage or disengage with the coupling hook in a distance of, say, $\frac{1}{64}$th of an inch, or in practice $\frac{1}{16}$th of an inch. The second requirement demands that the spring shall be so carefully shielded, from casual injury and wear and tear, within the solid head of the coupling that they shall last as long as any other portion of the coupling and continue reliable to the very end. Solid coupling and absence of jerky motion is ensured by the same conditions as No. 5, but their subsistence under all conditions of service requires certain structural peculiarities which merit careful consideration, and are well exemplified in the Van Dorn coupling under consideration. In going round curves both coupling and draw bar must be free to swivel so as to assume a true tangential position to the curve at the point midway between the car ends. With the single or four-wheel type of truck this is effected by fastening the drawbar by a universal joint to a draw plate which is bolted to the centre of the underframe of the car body. This universal joint is free to act in two planes only, so as to avoid all twisting in the coupling head. The ball piece is attached to the drawbar by fishplates which allow of wear in the ball, to the extent of $\frac{3}{8}$ths of an inch, being taken up, and the joint is cushioned with India-rubber washers. This practically ensures at least a life of five years in the joint without repairs or sensible elongation. In double bogie and maximum traction cars the drawbars extend to the king pins and swivel around these. The draw bar

Digitized by Google

consists of either a plain flat steel bar or of a "T" section, the latter being specially suitable for very heavy traffic. In the case of the flat bars, which are often of 1 inch × 8 inches section, the coiled springs, which cushion the pull, are fitted in the car end of the coupling head, while in the T-section bars (80 lbs. to the yard) they are placed in a special holder close to the king pin. The heads are supported by steel carriers beneath the car balcony ends, as shown in the accompanying figures. The coupling hook forms a common pin and link coupling at one end, which meets requisite No. 6, as it is capable of use with any non-automatic coupler. The heads are furnished with two pins either of which can be used and their life consequently doubled. Fig. 76 shows the coupling heads ready for coupling, and fig. 77 the two heads united. The coupling can be placed in either of the drawbar heads, when the hook enters the opposite one with the pin in the sloping hole, the springs in the inner side of the head are sprung out sufficiently to allow the hook to pass round the pin and lock. To uncouple, the pin in the sloping pin hole is pulled up, and coupling and uncoupling is readily effected if required in $\frac{1}{64}$th of an inch.

(To be continued.)

ELECTRIC HEATING INSTALLATION.

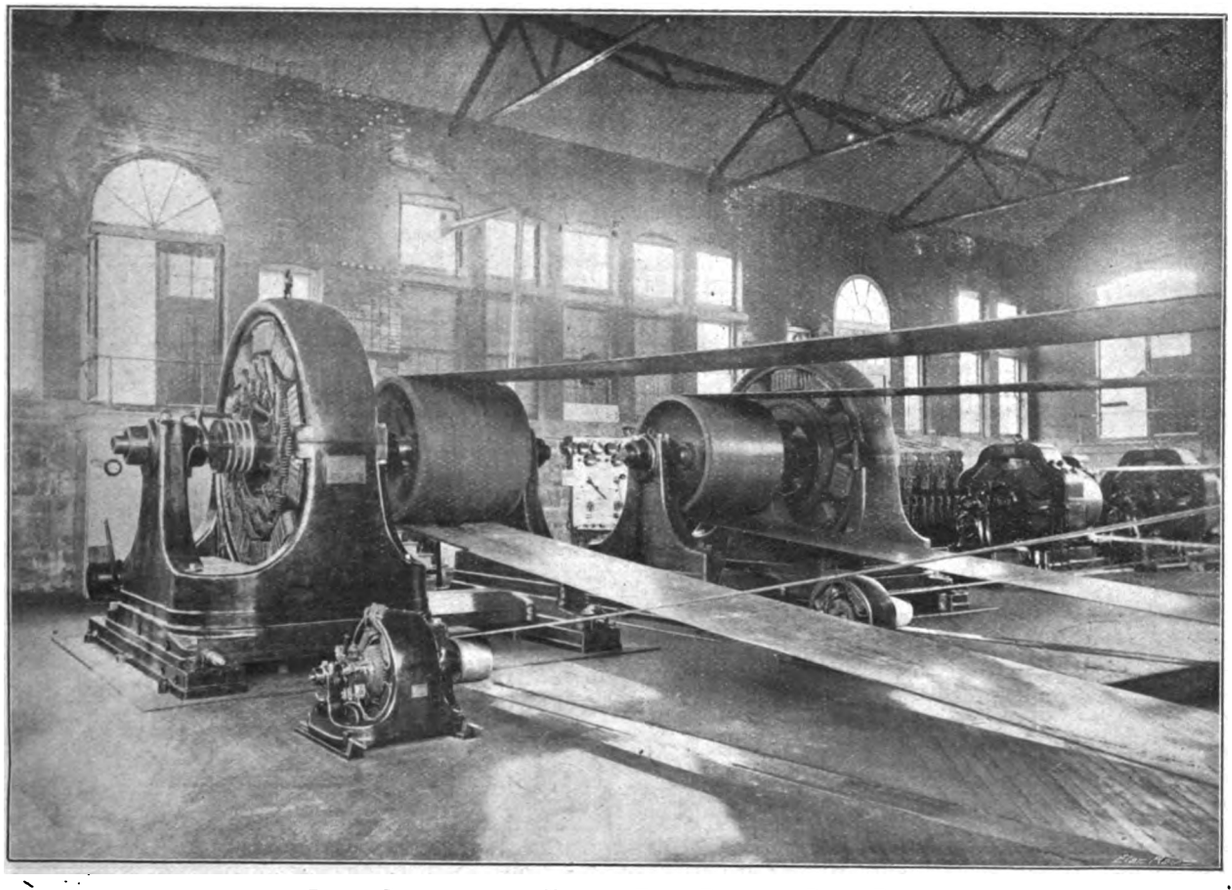
By O. E. DUNLAP.

In their new Hospice of Mount Carmel, at Niagara Falls, the Fathers of the Order of Mount Carmel in America have taken advance steps in the matter of electric heating, and the installation they have perfected is not equalled in the world.

Away back in the early twenties the first little chapel or shrine was built, and in this place the Catholics from all countries have worshipped. In the grandeur of the great cataract the late Archbishop Lynch, of Toronto, early saw an inspiration for devotion, and petitioned Pope Pius IX. to grant all the favours and privileges of the European sanctuaries to the little shrine at the Falls, with permission to transfer the privilege to a new shrine when completed. When the structure is completed as planned it will form one of the greatest buildings for architectural beauty and completeness of detail in America. At present the structure consists of the main building and one wing, and in the course of time the hospice and shrine will be combined. Then the shrine will occupy the centre between the two wings, the northernmost one of which will be the home for guests or pilgrims, and the southern one will be used as a monastery. The institution is on the same original plan as the famous hospice of Mount Carmel on the Mount of that name in Palestine. However, the hospice at Niagara Falls is modern in every particular, and founded on the latter day principles of the order of Carmelite Fathers.

Standing on the bluff back of the Falls, the hospice occupies a site unequalled in the world for beauty of surroundings. It is far enough back from the Falls so that the spray cloud does not reach and fall upon it, and from the upper windows the magnificent panorama of the Falls and gorge is spread before the eye. The present wing forms an L, the length of the sides of it at the foundation being 200 and 250 feet, while the height from the ground to the top of the towers is 85 feet. The buildings are of stone, the front being beautified with an arcade having massive granite columns.

The hospice is located about two miles from the power house of the Niagara Falls Park and River Railway, in which station the Canadian Niagara Power Company have two generators installed for a temporary power service. It is from the Canadian Niagara Power Company that the Carmalite Fathers get the electric power used in the building. As it stands to-day the building contains 200 16-C.P. incandescent lights. For lighting the building, for cooking, and for heating water 25 H.P. is being used, while 75 H.P. is, in time of need of such service, used for heating the lower floor of the building, which comprises 11 bedrooms, a dining room, reception room, office,

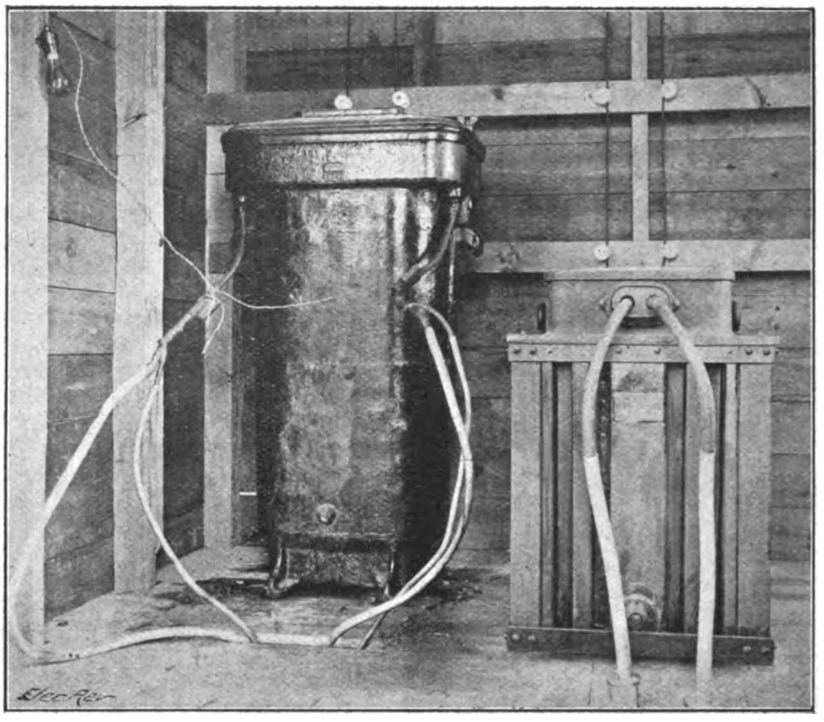


Power Station of the Niagara Falls Park and River Railway.
Where the Temporary Plant of the Canadian River Power Company is located. Showing Generators.

Digitized by Google

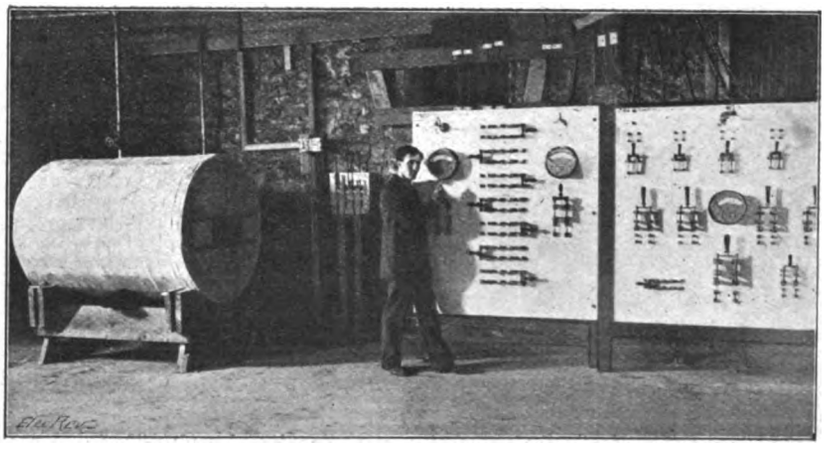
and the corridor. The corridor is 120 feet long, 10 feet wide, and the ceiling has a height of 15 feet. In this corridor are located nine 4-H.P. heaters. The bedrooms are 10 by 12 by 15, and in each is located one 4-H.P. heater with changeable heat switch of two heats.

The hospice transformer house is located about 150 feet west of the main building. It is a small wooden structure,



Transformers.

and over it tower two poles with a double cross-arm from which the wires descend to the station. In this transformer house are located two 30-KW. Westinghouse and one 25-KW. General Electric transformer, primary 2,200 volts, and three-phase secondary 110 volts. From this station the current is transmitted to the switchboard in the main building through an underground cable.



Switchboards and 400-Gallon Tank (water electrically heated).

The switchboards of this novel installation will be seen in the illustration. The panels are of white marble. The switchboard with double-throw switches controls two phases of the current, while the third phase is controlled by the other switchboard adjoining, and is used for cooking, lights, &c. Both switchboards are so arranged that either transformer can be used independently of the other for either purpose.

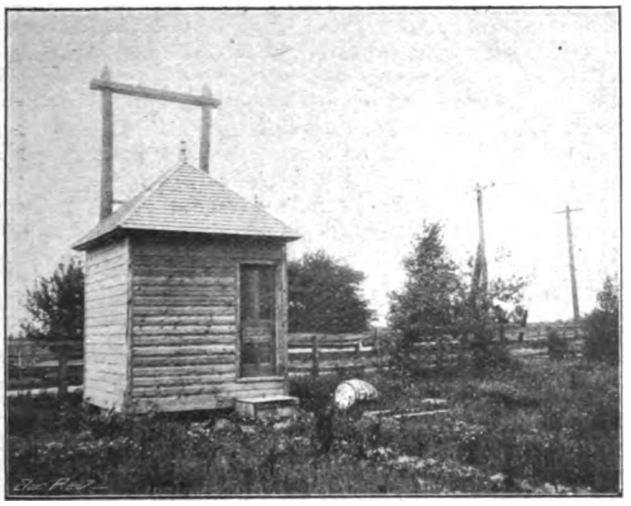
The hospice is also equipped with two hot-water boilers, both of which are operated by electricity. One of these has a capacity of 400 gallons, and is to be seen to the left of the switchboard in the illustration. The other has a capacity of 150 gallons, and is located in the south corner of the switchboard room. The 400-gallon boiler is used to heat water for the laundry and bath room. It takes a current of 120 amperes, being divided into three heats. The 150-gallon boiler takes 125 amperes, and is also arranged for three heats. This boiler is used for quick boiling. Both boilers are covered with 2½-inch asbestos covering. An important feature is that all water is boiled when the current is not being used for any other purpose. In the 400-gallon boiler water is raised from 60° to 212° in six hours with full heat.

In the butler's pantry there are three 5-gallon urns and a chafing dish, all electrically operated. In the kitchen are found an electric combination range and three ovens. The range has a heating surface of 6 square feet, and each square foot of surface has a switch and can be controlled to either full or half-heat. The largest oven takes 50 amperes, and is so arranged as to cook four 25-lb. roasts at one time. The two small ovens each have three compartments, and each consumes 23 amperes at 10 volts. On the door of the large oven there is a thermometer, which shows the heat and states the temperature through the

Digitized by Google

different time of roasting and baking. As the point of baking or roasting is indicated, the cook can make no mistake. As the heat is uniform, the cook is enabled to have her output of food uniformly cooked, and there is no burning or over-roasting. In the small ovens, bread can be baked in 18 minutes, and one day in June a dinner for 250 people was successfully cooked in this electric kitchen. One most gratifying feature to the cook in charge of this kitchen is the manner in which she can regulate the heat. Then all the pots and other dishes are always nice and clean, there being no deposit of dirt on them as from gas or other fuel.

While it is not possible at this time to make a very extended comparison of the cost of the work done by this installation, with what the same results would cost by other means than electricity, some general statements can be made that are of interest. If the cooking and heating were done the old way, they would require the services of



Transformer House.

two men, whereas they now require the services of a woman only. The man who has charge of the electric plant also looks after the office, and, in fact, has general supervision of the building. No extra help is required to look after the installation, the man in charge simply looking the plant over occasionally.

The annual cost of the electric energy used in the building for cooking, lighting, and heating water, is $625, which is 25 H.P. at $25 per H.P. If these things were done with coal as fuel, the cost would be $1,140. In the power the monastery or hospice uses for heating, it is at present exceptionally fortunate. Such supply of power is required for only about six months in the year, and as the power station from which the supply of current is received has not such a great demand on it for its energy during these months, as in summer, owing to fewer cars being run, there is a surplus of power which the hospice enjoys at a rate about one-fifth that paid for the 25 H P. above referred to. This is indeed an exceptional consideration, but under such circumstances it is evident that they can afford to use electricity for heating purposes.

In previous winters the power station of the Niagara Falls Park and River Railway has been greatly annoyed by the gathering of anchor ice at the inlet, and this has resulted in the installation being shut down for days at a time. Of course, when the Canadian Niagara Falls Power Company get their proposed new station running, it is not at all likely that the ice will bother its operation to this extent, but then the ice on the Canadian side above the Horseshoe Fall is likely to be far more troublesome than it is to the Niagara Falls Power Company on the New York side, the water conditions being quite different. However, the experience of the past winter, which was most severe on all the Niagara power companies, has developed the conviction that under such conditions, where ice is likely to bother a plant used for electric heating, it would be wisdom to instal a combination electric and fuel system of heating water, so that when the ice bothers the operation of the electric apparatus fire could be put under the boiler to heat the water which would otherwise have been heated by electricity. In other words, instead of carrying the electric current through the building for heating purposes direct, it would be better to apply the current to the boiler, and have a hot water system of heating. Then, should there be an interruption of the electric service, the fuel combination could be effectively used. It would seem that in a case like the hospice, this would be an ideal system, for all the results obtained at Niagara have been thoroughly satisfactory.

The electric plant in the Carmelite hospice was installed by Mr. A. Harth, an electrical engineer who has given much attention and study to the question of heating and cooking by electricity. The apparatus was made by the Hathaway Electric Heating and Engineering Company, of New York.

CORRESPONDENCE.

Converting Old Electric Lamps into New.

I have read your article on the subject of "Renewable Incandescent Lamps," also the various remarks of your several correspondents, with pleasure. Now, as I claim to be the *first and original Inventor* of the above process, perhaps a few remarks from me may be interesting and of use to the electrical trades, also tend to put the subject matter on a solid base. For in the face of facts, why £100,000 should be asked for a presumed patent is more than I can comprehend. For in the face of my completed patent No. 11,802, which is dated as far back as June 30th, 1888, everything of importance relating to the subject of converting "old lamps into new" is covered in my patent, and more, too, than is claimed by Messrs. Howard and Mayer; therefore, in the face of these facts, I do not consider their patent is worth a "£10 note," much more the £100,000 asked for it. Any electrical firm desirous of going into the renewable lamp industry, can do so without the least fear of infringing anybody's patents; moreover, the elongated and expansive type of bulb used in the proposed new system, upon which so much importance is laid, was also patented by me in a former patent taken out by me as far back as December, 1883, and, singular to say, my 1883 patent, covering the elongated and expansive bulb, was procured by Messrs. Hazeltine & Lake, the very agents who have taken out the patent for Messrs. Howard & Mayer, and if my memory serves me right, the latter gentleman, at the time I was in Germany teaching my system of manufacture, acted as consulting engineer to the very firm who purchased the German interests in my renewable lamp patents, but probably the German-Edison Company, the Seel Company, or Mr. Carl Rhoeder, of Vienna, all of whom know of its existence, would be able to confirm this point, as they all were conversant with my work, the two latter firms having founded the lamp industry in Germany and Austria partly under my patents of 1883, and any expert sufficiently interested in the subject of lamp manufacture has only to compare the drawings and descriptive matter of my 1883 and 1888 patents to decide the questions under discussion and prove who is the original inventor of the system. I may here say in my patent of 1888, that the invention clearly states that the chief object was to re-use and make up soiled or damaged incandescent lamps, repair same, and to convert old lamp materials into new lamps, which I proposed to do by utilising the waste materials previously used in lamp manufacture, a description of which my patent agents said would cover everything appertaining to the converting of old lamps into new and a direct bar to future inventions of this class. Probably the best and most profitable part of my invention is explained in the following descriptions, viz.:—

Digitized by Google

(*a*). The methods of standardizing the filament.

(*b*). The manner of utilizing the old filaments to manufacture new lamps of lower voltage and candle-power.

(*c*). The improved method adopted in making a good mechanical joint between the filament and leading-in wires.

(*d*). The methods adopted for carrying the multiple connectors through the bulb for high candle-power lamps of, say, 100 to 1,000 C.P. A very important feature which is now generally adopted by all lamp makers.

(*e*). The methods adopted for reducing the vacuum of the lamps prior to remaking same up into new lamps.

(*f*). The methods of making semi-metallic filaments which I still maintain are the best (when you know how to make them), for very low volt lamps when used for battery electric lighting, and especially for night lights or photographic purposes where a great light is only required for short durations, and the watts used to produce the light of no moment as to cost of energy consumed, for which this class of lamp, which can be greatly overrun, is specially applicable for the purpose named.

I may also say that I was the first inventor who made multiple filament lamps, and monopoly of which could have been easily secured by this patent had the claim been upheld against infringers of my rights. My inventions were also patented in France and Belgium, also patents applied for in Germany and America, all of which several rights were sold, and certain parts of the said invention have been ever since profitably used by the purchasers of the said patents, who have sold millions of lamps made under my patents, although sold under other names. I have no doubt your readers will say, when they read these facts, Why on earth did not Shippey Bros., Limited, sell this patent, or work the Shippey process in England? Why was it not sold for £50,000 or £100,000 when it was apparently the only lamp patent in existence of its kind under which lamps could be made and repaired without infringing Edison & Swan rights? That is just the point which requires explanation, and which has puzzled everybody until counsel's opinion was obtained, and, in fact, the patents were privately sold for £20,000 to a company of promoters, and a prospectus was actually printed re-selling my patents to the proposed company for £100,000 for payment of patent rights, and also providing £40,000 for building the works and plant, and providing capital for working the inventions. But it was not to be; fate willed it otherwise. A splendid and profitable business could have been established, certainly with a far greater success in the year of 1888 than now, for the simple reason that in 1888 electric lamps were selling by the Edison and Swan Company, and other makers, at from 3s. to 25s. each, according to type of lamp and candle-power. Consequently, at such splendid prices it can easily be understood that it was then well worth while repairing old lamps and re-using the materials for making up new lamps; but to-day it is another matter, and a horse of different colour, considering the low market price of incandescent lamps to-day; consequently the repairing of same is not now worth the candle. As an instance, my company holds in stock to-day, as is well known, some 20,000 to 25,000 lamps of different types and voltages, 50 volts up to 110 volts, as made in Germany, Holland, and America, many of which have been made by the manufacturers under my own original patents, under *nom de plume* titles, in the very works originally founded by us and our associates, and these special lamps, I may say, we are selling at the following market prices:—German make, 5s. 6d. per dozen; Dutch and Belgium makes, 6s. 6d.; and selected Americans at 7s. 6d. and 8s. per dozen for gross lots, and, moreover, from which price we allow regular consumers of our lamps 1s. per dozen for all cap and lamp ends returned to us intact with platinum supports, for which parts and materials there is always a demand, as the holders and platinum can be used over again, and to-day there are three or four firms who make a regular business in collecting from users the old and used-up electric lamps, a business which was not thought of until the advent of my patent in 1888; and, in fact, the only parts of any value are the platinum and brass base caps, for since the Edison and Swan patents have all expired the old glass and filament is no longer of any value, it being much more expensive to re-make up the old lamps than by making a perfectly new lamp with improved filament and new glass bulb. Therefore the idea of asking the public to subscribe £150,000 to carry out the objects proposed by the Renewable Lamp Company seems absurd in the face of my expired patents, and I cannot but express my astonishment to find certain names who have associated themselves with the development of such a scheme, and I fear with such dead weight of useless capital; if the shareholders expect any dividends they will be woefully disappointed, and I would say if there is any money flowing about the Stock Exchange or in electrical circles for business of this nature, or for even incandescent electric lamp manufacture, I will undertake as an expert lamp maker to construct the finest factory, with all the necessary plant, machinery, and appliances required to turn out, say, four million of lamps a year for less than £40,000, and with £10,000 working capital as ample to carry out the objects in view, and pay good dividends on capital to this extent. Now comes the pith of the whole business, viz., the real cause and reasons why my "renewable lamps patents" were never exploited in England simply rested on one legal point. Eminent counsel's opinion was obtained prior to the registration of the "Shippey Electric Lamp Company," for under legal advice his opinion killed the whole business and covered by a few works, for eminent counsel, after complimenting my patent agents on the construction of their specification and upon the merits of the invention, his opinion was briefly as follows:—"*The very making up of an incandescent lamp of high resistance with any type of carbon filament in vacuo which could be used successfully in electric lamp circuits would be a colourable infringement of the Edison and Swan patents, no matter how the filament was made or even the class of materials used.*" Even though it was proved that royalty had been paid on same, it was considered by counsel that it would still be held to be an infringement of Edison's memorable patent, and as I was personally already legally restrained by law from making incandescent lamps of any kind of a colourable nature during the unexpired term of the Edison & Swan rights, and having already sold the patents to the present company, not a cent of the £20,000 to be paid by the promoters would have come to me for my personal benefit, and having no desire to be committed to Holloway for contempt of Court, I thought it best to take a back seat rather than run the risk or expend more money in law, having already expended over £4,000. Hence the matter fell through, and the only reason why the Shippey Electric Lamp Company was never formed; for this reason alone a valuable invention was prevented being worked, and a good and profitable business frustrated by the arm of the law, although a bitter pill for me and my then associates, that the matter fell through upon facts stated.

I enclose you copies of the specification of my patents for your perusal, which I think covers the whole ground of the subject matter under discussion; and as my patents have run through the second and third editions, it clearly shows that these inventions have interested lamp makers, although at heavy costs to me as the inventor. I must apologise for the length of this communication, but as the subject matter is one of national importance to the electrical trades, and especially lamp users, this must be my excuse for fully explaining the position of affairs, so far as it concerns my patents. If you can find space to record these facts, please do so and oblige.

Arthur Shippey.

Copper.—The *Mining Journal* says that owing to the development of the electrical industries in Germany, the increase in consumption of copper and lead appears to be greater than in any other country. In 1897 the consumption of copper was 92,148 tons, and that of lead 133,239 tons, whilst in 1898 the consumption of copper was 98,160 tons, and that of lead 159,229 tons. Germany produces 7 per cent. of the world's supply of copper, and consumes 22½ per cent., whilst its production of lead is 17½ per cent. of the world's supply, and its consumption 20 per cent.

SOME NOTES ON THE ELECTRICAL MACHINERY AT THE COMO EXHIBITION.

By KENELM EDGCUMBE, Assoc.M.Inst.C.E.

(*Continued from page* 265.)

The Technomasio Italiano had on view a number of continuous current motors in which speed regulation was performed by varying the length of air gap. Each of the two magnet limbs (the motors are of the ordinary horse-shoe type) is capable of sliding towards, or away from, the other. They are actuated by a right and left handed screw, which is turned by a hand-wheel at the side of the machine. A small pointer at the top indicates the relative separation of the poles, and hence the speed at which the motor will run. What advantages such a system possesses, as compared with the ordinary method of varying the shunt resistance, is not very clear. The alteration of speed can, of course, be made more gradual than is possible with this latter method, but on the other hand, it is necessary to go to the motor each time, instead of it being possible to have a controlling switch placed in some convenient position.

Messrs. Schuckert, among a fairly large number of machines, showed a so-called "Licht und Kraft" three-phase dynamo, which, as its name implies, is designed to supply a mixed load of power and light, without its being necessary to equalise the distribution of the latter over the three phases. The arrangement would appear to consist in running the motors off all three phases in the ordinary way, while the lamps are connected across two phases only, of the star coupled armature. As these two phases have obviously to carry more current than the other they are consequently wound with larger wire. It may be remembered that a somewhat similar system is in use at Schwytz in Switzerland, where Messrs. Brown, Boveri & Co. have adopted the expedient of joining the step-down transformers in mesh, and of connecting all the lamps on to one only of them. Messrs. Schuckert also exhibit a high tension quick-break switch for use with pressures up to 6,000 volts, in which the break takes place between a number of smooth brass cylinders, which are normally in series and touching one another, but which can be suddenly drawn apart, thus dividing the arc up into a large number of parts.

In the Dynamo Gallery was to be seen a 15-ton travelling crane, designed and constructed by Messrs. Larini, Nathan and Co., of Milan, and driven by three-phase motors built by Messrs. Gadda & Co., also of Milan. Each of the three motions is actuated by a separate motor, an ingenious device being employed in starting. Instead of the resistances being cut out of circuit by a cord or lever, a species of centrifugal governor is fixed to the motor shaft in such a way that as the latter gets up speed the switch arm is slowly moved over the resistance contacts. It will be at once seen that by this means it is merely necessary to close the motor circuit, and the maximum permissible starting torque is automatically obtained, without any fear of destroying contacts, &c. It may, at first sight, appear a needless complication to replace so simple a process as switching on a motor by one which is comparatively complicated. But when it is remembered to what rough usage a crane is ordinarily subjected, it will probably be admitted that it is a step in the right direction. Since, in the case of a three-phase motor, it is impossible to vary the speed electrically, it is in this instance done in the following manner:—The load is carried by an endless chain passing round two chain wheels, of which one revolves four times as fast as the other. For slow speeds only the latter is caused to rotate, while for high speeds (5 : 1) an electro-magnetic clutch sets the other wheel also in motion. Steel worms, gearing into phosphor bronze worm wheels, are used throughout, the thrust being taken up by ball-bearings. Extremely high efficiencies are claimed for these gears, while the commercial efficiency of the hoisting motor and tackle is said to exceed 50 per cent.

Messrs. Siemens & Halske had a fairly large exhibit of instruments, fittings, &c., of which their system of "safety fuse cartridges" may perhaps be mentioned. The objects kept in view in their design were: firstly, to produce a fuse which should act with absolute certainty on 250-volt circuits, and, secondly, to devise some means by which it should be rendered impossible to accidentally replace a given fuse by one of greater carrying capacity.

The fuse wire is wound, in two parallels, under and over radial projections. Thus, when a fuse blows, the resulting vapour is split up into six parts, so that the formation of an arc from terminal to terminal is absolutely impossible. The box containing the fuse wire is made of a special cement which, after repeated tests had been made with porcelain and other materials, was found to give the best results.

The fuses are made in various sizes to carry from 2 up to as much as 30 amperes, lead wire of the following dimensions being used:—

Amperes ...	2	4	6	10	15	20	30
Area in sq. mm.	·75	1	1·5	2·5	4	6	10

It will be gathered from what has been said that while preventing *accidental* mistakes, the system does not in any way prevent the *wilful* substitution of one fuse for another.

This same firm also shows several forms of lightning protector for overhead lines, and it may be mentioned that their now well-known "horn" type (see fig. 8) is in use throughout

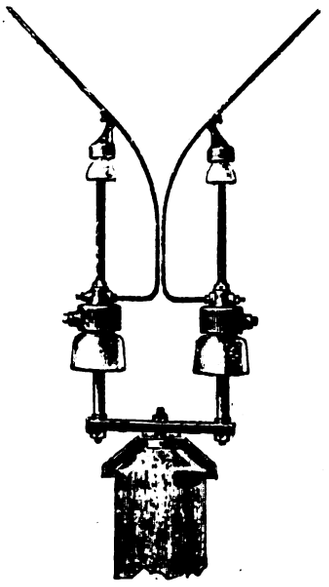

Fig. 8.

the grounds of the Exhibition, and, in fact, is to be seen on almost all the overhead lines of Northern Italy. Fig. 9 shows diagrammatically the method of connecting these protectors to a three-phase system. A is a fuse between the line and the protector, and B is a small self-induction, consisting of, say, 8 or 12 turns of cable, which is usually placed where the line enters the power station.

Of the large number of primary and secondary cells exhibited three of the former class may be briefly noticed. One of these is the "Hydra" dry cell manufactured by the Elektricitäts Actien Gesellschaft Hydrawerk, of Berlin. The chief peculiarity of this cell is that it contains a reservoir of solution, so that it never dries up, the life being thereby greatly prolonged. Prof. G. von Knorre gives the following table showing the capacity of various dry cells, tested by himself. From this it will be seen that the "Hydra" has by far the largest capacity, but as the relative weights of the different cells are not given, the comparison is not of much value:—

Type of cell.	Resistance of circuit.	Capacity in ampere-hours.			
		No. 1.	No. 2.	No. 3.	No. 4.
Liman & Obenlander ...	1 ohm.	1·703	1·721	·933	1·104
Vogt	1 „	1·180	1·165	1·511	·918
Gassner	5 „	·614	·230	·487	·321
Hydra	1 „	5·569	2·246	4·822	4·859

Messrs. Marelli showed the "Cupron" cell, which is a modification of the well-known Edison-Lalande cell, and consists of two plates of amalgamated zinc, between which is

Digitized by Google

a plate of copper oxide (CuO), the whole being immersed in a solution of caustic soda. The advantages claimed for this cell are, firstly, that it does not deteriorate by standing idle (a thin layer of oil is poured on the top of the liquid to

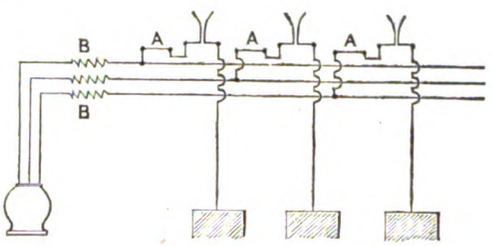

Fig. 9.

prevent the absorption of carbon dioxide from the air), and secondly, its great constancy and freedon from polarisation. The curve, fig. 10, shows the variation of voltage at a comparatively heavy rate of discharge, namely, 1·55 amperes. From this it will be seen that after the first five hours the voltage remains practically steady at ·8 volt. The high initial voltage of 1·1 is said to be due to the free oxygen occluded by the copper oxide. The capacity of the cell under these circumstances was 53 ampere-hours, while at a discharge rate of ·15 ampere the capacity rose to 60 ampere-hours. The internal resistance of a cell of this size is only ·06 ohm, and

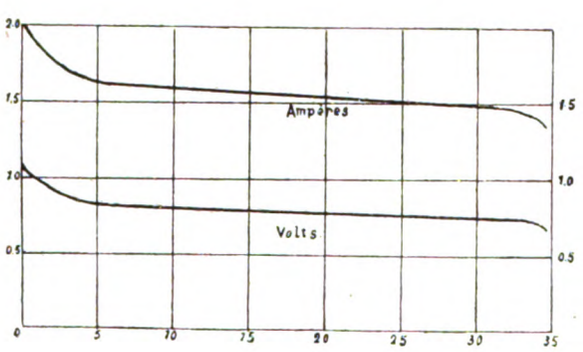

Fig. 10.

its weight 3 lbs. The consumption of zinc is said to amount to less than 2 grammes per ampere-hour, and that of the caustic soda to 4 grammes, at a total cost of about 2s. 4½d. per KW.-hour. The "regeneration" of the copper oxide takes about 24 hours at the ordinary temperature.

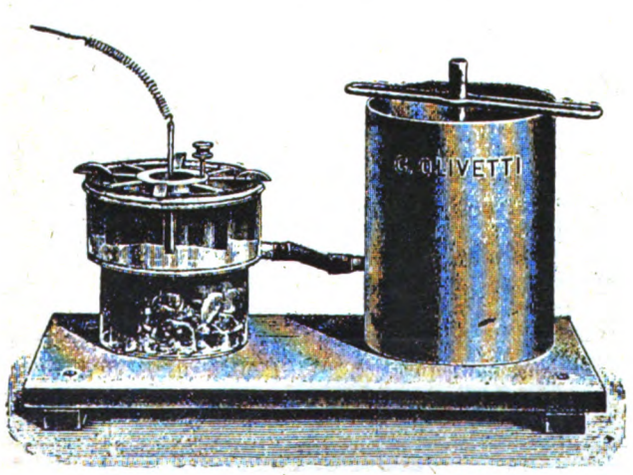

Fig. 11.

One other cell deserves mention. This is a modified Daniell manufactured by C. Olivitti, and intended especially for intermittent use. Fig. 11 shows this cell which, as will be seen, consists of two vessels connected by a short rubber tube. In the lower half of the left-hand vessel is the copper plate and copper sulphate solution, while in the upper compartment is the zinc electrode. When required for use a plunger in the right-hand vessel is lowered, thus forcing the solution it contains into the other receptacle, where it surrounds the zinc. After use the plunger is again raised, and the solution drains away from the zinc.

Among some instruments, &c., exhibited by the Museo Industriale, of Turin, was to be seen a novel device, due to Prof. Guido Grassi and Signor F. Lori, for starting single-phase motors of the Brown type. These motors, it will be remembered, require capacity in their running coils at starting, and, as ordinarily constructed, the condenser consists of a large number of parallel metal plates, dipping into a solution of carbonate of soda. It will be readily seen that for a large motor the apparatus becomes extremely cumbersome, and that short circuits are likely to occur. In the device shown by Prof. Grassi, the condenser is replaced by a simple form of Wehnelt interrupter, consisting of one or more carbon rods dipping into dilute sulphuric acid, and surrounded by a sheet of lead, forming the other electrode. The electrostatic capacity of such a cell is extremely high, and when applied to a 10-H.P. Brown motor, the starting torque was greatly in excess of that obtained with the ordinary condenser, though the latter was considerably more bulky. Further particulars of this system will be awaited with interest.

Two companies were offering power on the large scale for factories and other purposes. One, l'Elettricita Alta Italia, of Turin, supplies current partly drawn from a water-power station at a distance, and partly generated by a steam engine station in the town. The other is the Societa Generale Italiano Edison, of Milan, who receive their current from the water-power station at Paderno on the Adda. The distance is some 22 miles, a three-phase 12,000-volt transmission being employed. It may be of interest to note the charges made by these two companies. In the case of Milan, the following will give a rough idea of the cost of light and power. For light, by meter, the price is roughly 9d. per unit, with discounts of from 4 per cent. to 22 per cent. according to the energy consumed. For power, the cost of a unit ranges from 4½d. to 6d., varying, of course, with the size of meter used and with the consumption guaranteed. Thus for a 20-H.P. motor, the price per unit would range from 2¼d. to 1d., according to the number of hours run per day. Up to the present there has been no demand for current for electrolytic purposes. The company also let out arc lamps at the rate of 19s. per annum. This charge includes repairs and recarboning daily, the carbons, however, being supplied by the user.

The Turin Company supply power for small motors (up to 7 H.P.) at 1d. to 1¼d. per unit according to the consumption. For larger motors, *e.g.*, those above 50 H.P., the charges vary from £9 10s. to £7 10s. per H.P. per annum. For lighting the price per unit ranges from 8d. to 5¾d.

Of the various applications of electrical energy, one which seems so far to have received but little attention, is the electrolysis of water for the production of oxygen. Probably the chief reason for this is that twice the volume of hydrogen is simultaneously produced, and that the market for this latter gas is extremely limited. To overcome this objection, Messrs. Garuti & Pompili, of Tivoli, who are the makers of an apparatus for the electrolysis of water, are endeavouring to introduce the oxyhydrogen jet for various purposes. For its use in the various metallurgical processes the advantages which they claim are :—(1) The reduction in first cost of plant, which is said to amount to upwards of 50 per cent. ; (2) reduced loss owing to oxidation ; (3) smaller space occupied ; (4) the time taken is often reduced by one-half ; (5) the possibility of producing at will either an oxidising, reducing, or neutral flame. For welding, its adoption in place of the electric system is recommended for the following reasons :—(1) The plant required is cheaper, more portable, and less complicated ; (2) the temperature of the electric arc is too high for many purposes ; (3) it is difficult to regulate ; and (4) it is deleterious to the eyesight. It must, however, be remembered that the oxyhydrogen flame has been known for a long time, and it is doubtful whether it is merely on the score of expense that its adoption has been delayed.

(To be continued.)

COSMICAL MAGNETISM AND ELECTRICITY.

By ARTHUR EDGAR COTTERELL.

A very interesting article under the title of "Atlantic Earth Currents," from the pen of Mr. E. Raymond-Barker appeared in the Electrical Review on June 9th, 1899, pp. 925-6, and it has occurred to me to subject the details which head page 926 to an analysis or examination. A serial article of mine, entitled "Electric Earth Currents Viewed Astronomically," appeared in the Electrical Review in 1897 (commencing on page 527, Vol. 41, No. 1,039, October 22nd), and was followed in 1898 by another on "Terrestrial Magnetism" (which commenced on page 370, Vol. 43, No. 1,085, September 9th). In the former I endeavoured to submit a

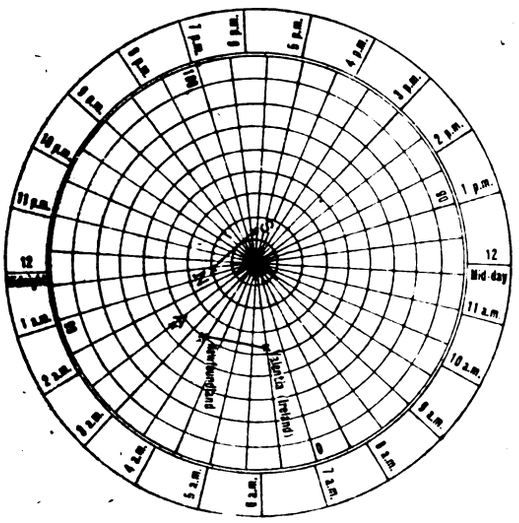

Fig. 1.

cosmical hypothesis in explanation of "Earth Currents," and in the latter I approached the question of "Terrestrial Magnetism" by asking, "Is the earth a huge magnet or merely the recipient of an ethereal line of force?" my endeavour being to substantiate the latter suggestion.

In the former articles I ventured to suggest an analogy to the dynamic production of electricity with certain celestial motions, in which the earth with a magnetic axis set eccentrically to its rotative axis formed the armature, as it were, of an immense dynamo, having the sun as its field.

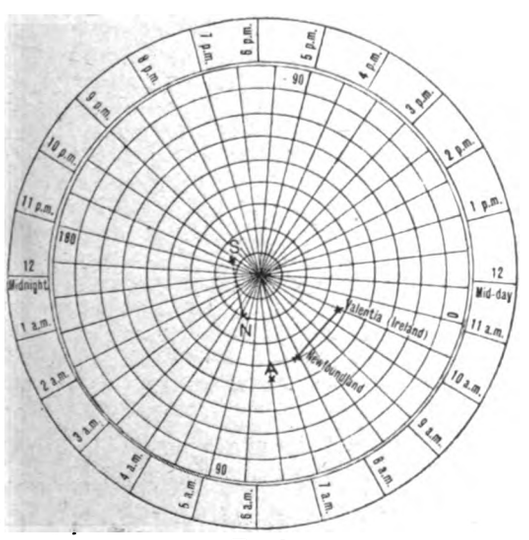

Fig. 2.

In the course of the arguments adduced I exhibited certain charts illustrative of the varying positions of the terrestrial magnetic axis in relation to the sun, which it seemed to me displayed remarkable coincidences with observed current effects as recorded at the Irish end of the Atlantic cables.

Mr. Raymond-Barker presents us with a brief summary of his records at the American side of the Atlantic, and I have ventured to apply the same to a similar analysis. The result is so very striking that I think that it is worth having attention drawn to the same. For simplicity I take the mean value of his figures from which we have the following:—

Date. 1898.	Zero.	Max. neg.	Zero.	Max. pos.	Zero.	Max. neg.	Zero.	Max. pos.
	a.m.	a.m.	a.m.	p.m.	p.m.	p.m.	p.m.	p.m.
July 14—18 ...	2.20	6.32	8 54	12 2	3 25	6 2	9 34	11.48

In order to examine the various magnetic phases as compared with the mean times above stated, let us take a chart of the Northern Hemisphere on which we must mark down the relative positions of the north and south magnetic

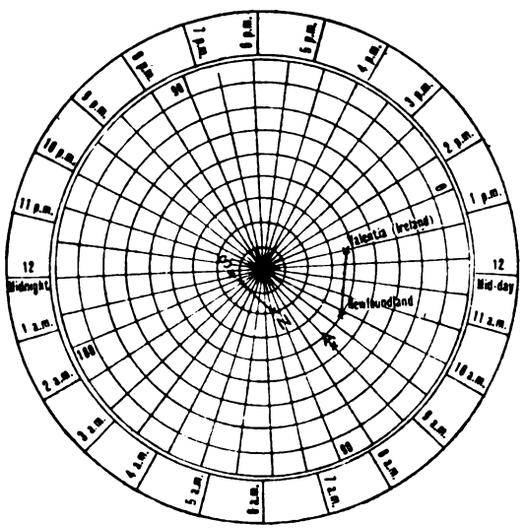

Fig. 3.

poles. This will enable us to not only see the position of the north magnetic pole, but also the relative position of the southern one.

Mr. Raymond-Barker's observations having been made on the shores of Massachusetts, we must now mark down the

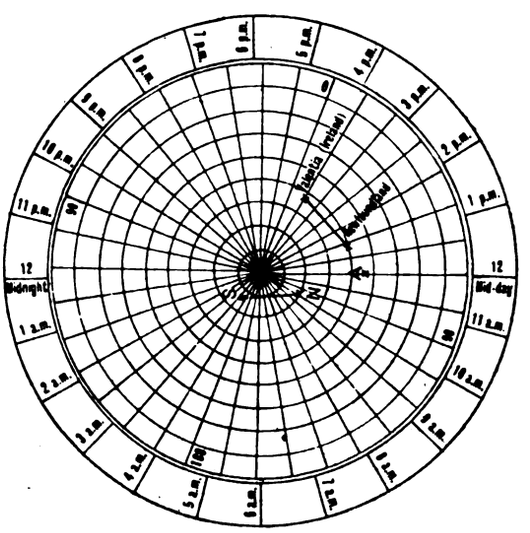

Fig. 4.

position somewhere about longitude 70° and north latitude 42° at "A." We also mark the direction of the Atlantic cable which runs more or less perpendicular to the axis of the magnetic poles, and so really forms a segment of an electro-magnetic wrapping as it were.

Around the outside of this hemisphere, we must now draw

Digitized by Google

a dial representing the 24 hours of the Solar day, the sun obviously being situated in the line of noon. If now we cut the hemisphere from the dial, and rotate the former within the area of the latter, a ready and simple comparison can be made of any desired positions.

The various positions occupied by the terrestrial magnetic axis in relation to the sun at the different mean times above stated are very full of interest, and are shown very clearly in the accompanying diagrams.

We will now proceed to turn our hemisphere with the dial to the various hours mentioned, bringing that line marked

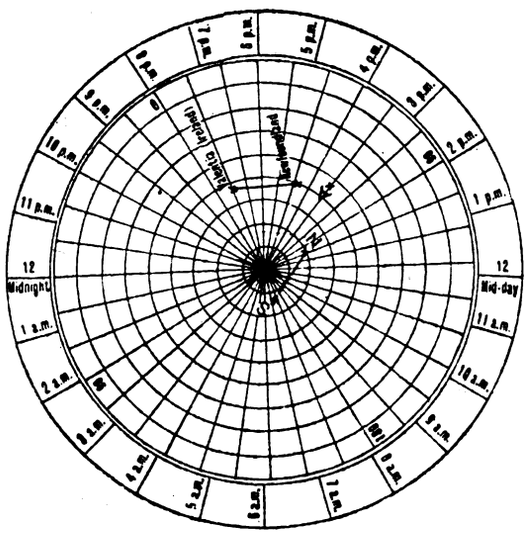

Fig. 5.

"A," and representing the American station, successively into its due positions.

First of all then (fig. 1) on turning A into line with 2.20 a.m., we notice that the north magnetic pole is at its greatest distance from the sun, which, as before stated, is in the line of noon on the dial. Next we move A forward to 6.32 a.m. (fig. 2) when the north and south magnetic poles assume a position approximately rectangular to the line towards the sun.

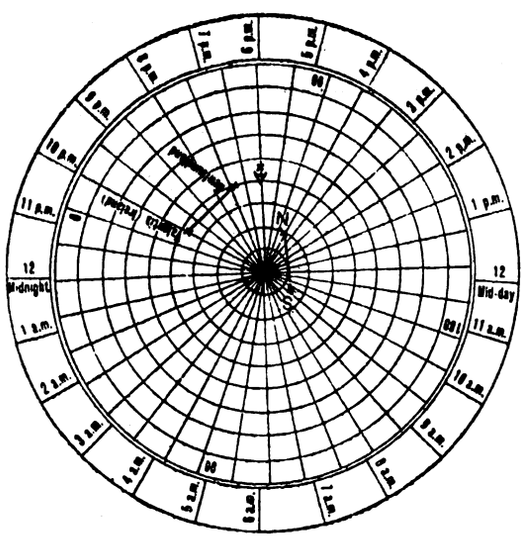

Fig. 6.

At 8.54 a.m. (fig. 3) the south magnetic pole is situated at or about its greatest distance from the sun, whilst at 12.2 p.m. (fig. 4) we notice that the north magnetic pole is very close to its nearest possible position, and the line of magnetic axis parallel to the Solar line.

At 3.25 p.m. (fig. 5) the positions are not quite so striking as those which have preceded. It must be remembered, however, that as the records were taken in July, when the inclination of the earth's axis is such that the northern hemisphere is almost at its greatest projection towards the sun, the north magnetic pole would be subjected to greater solar influences than at other seasons of the year (the Solstice, June 21st, and adjacent days, excepted). It is most interesting, however, to note that the north magnetic pole is at this time, viz., 3.25 p.m., just receding from its nearest daily proximity to the sun.

At 6.2 p.m. (fig. 6), the next position, we notice that the magnetic poles have reached their rectangular position in

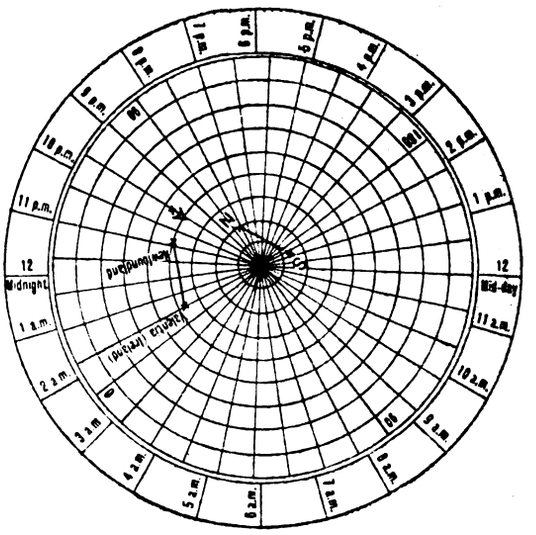

Fig. 7.

respect to the line to the sun, and in this connection it is interesting to remark that similarly with their rectangular phase at 6.32 a.m., or thereabouts, the currents are maximum negative. Turning our hemisphere again to 9.34 p.m. (fig. 7) we observe that the south magnetic pole is somewhere about its nearest position to the sun, another very striking phase.

And lastly, on bringing A round to 11.48 p.m. (fig. 8), we notice curiously enough that the north and south magnetic poles are parallel to the Solar line.

Briefly summarising these phases it may be said that :—

The maximum negative currents arise when the negative axis approximates to the rectangular position, as at about

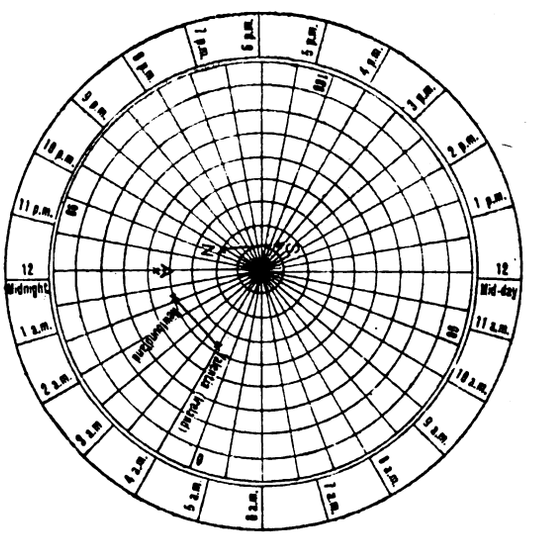

Fig. 8.

6 a.m. and 6 p.m., and the maximum positive somewhere near 12 noon and 12 midnight, when parallel to the Solar line.

The four positions when currents are zero occur when the north or south magnetic poles occupy their nearest and farthest positions in relation to the sun.

Remembering, then, that the earth's magnetic axis, which is set eccentrically to the rotation axis, must revolve around the latter, it is impossible to help being struck by the coincidence of the above-mentioned phases, and, moreover, it would seem proved that the magnetic electric relation

Digitized by Google

between the sun and the earth is of the most intimate order. The sun would appear to be quite capable of altering the earth's magnetism whether by magnetism of its own or by its heat rays.

ALUMINIUM PATENT LITIGATION.

Our Niagara Falls correspondent informs us that it is expected that the now somewhat famous suits over the patented process for the manufacture of aluminium will be heard on appeal in United States Court for the Northern District of New York, to be held in Utica, N.Y., next October, Judge Cox presiding. The case is titled the Cleveland Electric Smelting and Aluminium Company *v.* The Pittsburg Reduction Company, and is some years old. The suit is one wherein the Pittsburg Reduction Company is sued by the Cleveland Electric Smelting and Aluminium Company for alleged infringement on two patents issued about January, 1892, to Charles S. Bradley, involving, as claimed, the process practised at Niagara Falls in the manufacture of aluminium. In all there are 10 claims attached to the papers being prepared by the Cleveland Electric Smelting and Aluminium Company in the case. The patents were applied for in February, 1883, and therefore they date back to this early date as a pioneer inventor in the electric smelting field.

The nature of the claims set up may be judged from the following paragraphs taken from the patents:—

> The process of obtaining aluminium from its ores or compounds, consisting in passing an electric current through a forced portion of the aluminium ore or compound contained in an unfused body or heap of said ore or compound.
>
> The continuous process of separating or dessicating aluminium from its ores or compounds, consisting in fusing and maintaining the fusion and electrolytically decomposing the ore or compound by the passage of the electric current therethrough, and charging the pots with fresh quantities of the ore or compound as the reduction proceeds, substantially as set forth.

It is understood that these patents were purchased by the Cowles people, who are interested in the Cleveland Electric and Smelting Company, but who were then in Lockport in 1885. After their issuance from the Patent Office in 1892, a long litigation followed between the Cowles Electric Smelting and Aluminium Company and a patent lawyer in New York, Grosvenor P. Lowry by name, who had also made a purchase of the patents from Bradley, probably under the assumption that the so-called original assignment to the Cowles people was not perfect. This suit against Lowry was decided in favour of the Cowles Company, and they began the present suit against the Pittsburg Reduction Company.

In 1891 the Cowles Company sued the Pittsburg Reduction Company, under patents covering the same ground practically as those issued to the Cowles Bros., but that suit had to be withdrawn because of the Bradley patents, bearing an earlier date of application than the Cowles patents, issuing from the patent office and assigned to Lowry, who was then the American representative of the great aluminium company at the Falls of the Rhine, in Switzerland.

Charles M. Hall, the inventor of the process now used by the Pittsburg Reduction Company, is now with that company at Niagara Falls. It is said his early experiments were carried on in the Cowles plant then in operation in Lockport, N.Y. In 1892 the Pittsburg Reduction Company sued the Cowles Company under a patent that Mr. Hall secured. On trial the United States Court in Cincinnatti construed the Hall patent very broadly, and enjoined the Cowles Company from continuing the manufacture of aluminium, since which time their plant in Lockport has been closed. This suit has not as yet reached an appeal.

The process of making aluminium consists of fusing the materials from which the aluminium is produced in a large iron tank open at the top and lined over the bottom by a heavy mass of carbon. The electricity passes into the material fused by means of a number of heavy carbon rods 3 or 4 inches in diameter, the ends of which hang down into the liquid bath. The aluminium is deposited very much the same as nickel is deposited by electrolysis, and collects as a mass of molten metal below the fused bath of aluminous material. No heat but that evolved from the electric current is used.

As the litigation is already extended, the outcome of the suits will be watched with much interest at home and abroad.

EFFICIENCIES.

One of the evil effects of published tests is the use made of the figures obtained. It is well known that under carefully conducted tests a machine, or other appliance, will produce results that cannot be obtained in every-day work. This is particularly noticeable in stoking. Under the spur of some temporary incentive a stoker will secure results very much superior to his every-day work, and he will do it without actually knowing that he is doing beyond his average. A continual incentive cannot be maintained except by financial pressure in the shape of a bonus. When a bonus can be earned, and where an addition to the weekly earnings is particularly desirable, much may be done by the use of such instruments as a water-meter or the newer econometer. We have known in a steel works where the appearance of the chemist with his apparatus at the gas producers has at once improved the gas which was being produced, simply because the attendant knew that tests would reveal the degree of attention given to the furnace. All machines, be they engines, turbines, pumps, or boilers, have certain known efficiencies. The maximum efficiency ever obtained is known to some degree of approximation, and there is a tendency to use such maximum record in designing new plant, with the result that every detail of a new plant is probably proportioned to some maximum figure which is little else than ideal. If every item in a chain of machinery were thus designed, perhaps one might reach the efficiency alloted to it, and the remainder might fall short to an amount up to 10 or 20 per cent. In electrical transmission work, between the coal heap and the motor spindle, there is a chain of seven links, viz., a boiler, a steam engine, dynamo, step-up transformer, line, step-down transformer, and motor, the maximum efficiencies of which, may, for illustration, be assumed to be 75, 90, 95, 95, 90, 95, 80. The product of these efficiencies is 41·6.

Let each of the efficiencies fall off by the small amount of 2 per cent., and the final efficiency will be 34·8, or less than 84 per cent. of the first product. In other words, if a steam engine of about 840 H.P. was originally designed, the small average reduction of 2 per cent. in the efficiency of each link in the chain would demand an engine to be employed of about 1,000 H.P. Assuming the 840 H.P. engine to have been built to work at its maximum efficiency, it will be overloaded if worked up to 1,000 H.P., and all through the chain each link will be too small for the duty placed upon it, with the result of excessive depreciation and wear. The practical designer, who knows how far below the best results are the efficiencies secured in daily work, will provide for such by assuming what we may term the efficiency of the efficiencies. In a chain of efficiencies such as given above, the mean of the seven efficiencies is 88·5 per cent. If the product of the seven efficiencies or 41·6 be multiplied by this eighth efficiency, the final product is 36·8, or not seriously greater than the number 34·8 found by assuming a slightly reduced efficiency in each element. Investigated mathematically, the variation of the different efficiencies might perhaps be determined in respect to the relative probability of each variation, and the efficiency factor might be some figure more or less than the arithmetic mean we have employed for illustration. But it is extremely improbable that the probabilities of variation from the maximum could really be established with any marked accuracy, seeing that such factors enter into the problem as the personal equation of a stoker, and the behaviour of a long line of transmission in all kinds of weather, and the experiences of practice would seem to be met by using a final multiplier derived from the average value of all the efficiencies in the chain. Probably there are not sufficient existing data from which to estimate how far actual efficiencies fall below test values. Calling the various efficiencies in the chain $e_1, e_2, \ldots e_n$, the mean efficiency suggested above is

$$\frac{e_1 + e_2 + \ldots e_n}{n} = E,$$

the efficiency of the efficiencies. Should E, as thus found, prove to be too large a number, it would probably be sufficiently corrected by a constant, becoming $E - c$, where c is such a constant as a few practical trials showed to be necessary. c would obviously be a variable constant according to the probable nature of the plant, the attention likely to be bestowed upon it, its size, and importance. The effect of such a constant, substractive from the mean of the efficiencies, would be relatively greater in the case of a short chain than in a chain of many links. This is as it should be, a chain of few links being more affected by an abnormally low efficiency in one link than would be a longer chain, and this risk the constant would tend to eliminate with greater effect in the fewer links. In any assemblage of machinery there is almost a certainty of some one item being below expectation, either from inherent fault or from misproportion, whereby it is unable to work at its most efficient rate, and it is never safe to take a series of maximum efficiencies as the probable efficiency basis for the whole plant under the idea that, while some of the items will fall below the test efficiency, others will exceed their expected efficiency. Practice does not bear this out.

Where machinery is specially devised to be at times worked at part power, as turbines at part gate, or throttled centrifugal pumps, the item efficiencies to be taken as factors in the continued products for efficiencies must not be the maximum, or test efficiency, of the turbine, for instance, at full gate, but its test efficiency at such part gate. This is especially necessary in case of hydraulic machines of which the efficiency falls off so rapidly at part gate. In trying the method suggested above upon an example recently encountered, we find that the efficiency of a combination actually obtained accords very closely with the results given by the method.

BUSINESS NOTICES, &c.

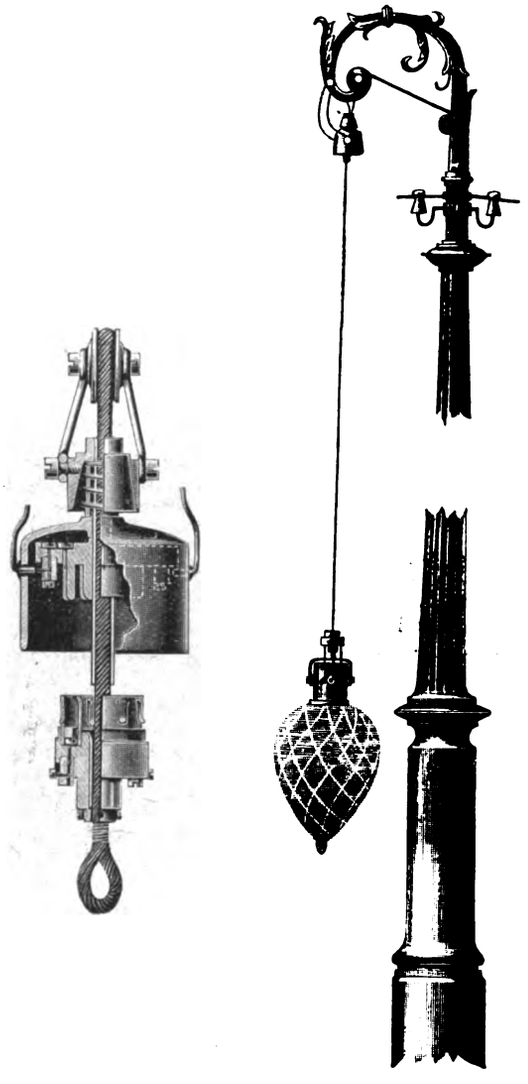
Accumulators in France.—A new company has just been formed at Clichy with a capital of £22,000 to be known as La Société Nouvelle de l'Accumulateur Fulmen.

Anglo-Swiss Trade.—A report has been prepared by the British Legation in Berne, proposing a scheme for the increase of trade between Great Britain and Switzerland. The establishment at Zürich, the commercial centre of Switzerland, of an Anglo-Swiss chamber of commerce with a depôt of samples of British goods is proposed.

Arc Lamp Coupling.—Mr. G. Braulik is placing upon the market a new coupling for arc lamps, by the use of which it is claimed that the unsightliness caused by lengths of conducting cable having to hang down is obviated. Counterweight methods are

Digitized by Google

asserted to have rendered handling of the lamps a more complicated process as well as endangering the insulation of the cable. Mr. Braulik's coupling, which is shown in the illustration (fig. 1) can be fitted to existing arc lamps (fig. 2). It is said to be suitable for all installations, and to be specially adapted to high tension. It consists of two contact boxes, one fixed for fitting on the roller where the lamp is to hang, and a movable one attached to the lamp. The contact springs are so arranged that all these parts are fixed on the lower plug for easy examination when the lamp is receiving attention, while on the top part they need not be so accessible, only a solid contact ring being used. The contact parts consist of solid metal rings with springs; the rings lie concentrically one in the other, so that swinging or turning the lamp does not break contact. The conducting



tube in the top part is insulated from the lower plug, so that any moisture that may drop from the cable used for raising the lamp does not touch conducting parts. The suspending cable goes through the whole of the coupling to ensure a meeting of the two contact boxes. All current-carrying parts are well mounted and highly insulated with porcelain, and protected from the weather by a solid cap. The apparatus, when hung, is supported by a spring, and pressure does not fall on the contact springs, nor are they affected by jolting. The fitting is hung by fixing a hook on the axle of cable roller, while the lower part with screws are fixed through the terminals on to the cable. In lowering the lamp, current is switched off, as by a double-pole switch, and shock accidents are impossible.

Bankruptcy Proceedings.—Mr. Sydney F. Walker, electrical engineer, Cardiff, filed his petition in bankruptcy on Thursday last week. It is said that the liabilities will not exceed £2,000.

Liquidations, Dissolutions, &c.—The Electrical Pioneer Syndicate, Birmingham, is winding up voluntarily, Mr. A. H. Gibson, 39, Waterloo Street, Birmingham, being liquidator. Creditors must send particulars of debts, &c., to Mr. Gibson by October 31st.

Creditors of the London and Lancashire Electric and General Engineering Company must send particulars of debts, &c, to the liquidator, Mr. F. A Franklyn, 48, Upper Thames Street, by September 30th.

Catalogues, &c.—Messrs. Baxendale & Co., of Manchester, send us illustrated price lists of switch blocks, pendants, brackets and other electric lighting and ball accessories, also the "Saxon" enclosed arc lamp.

The Bullock Electric Manufacturing Co., of Cincinnati, U.S.A., sends us a pamphlet in which there are described and well illustrated the Bullock engine type of generators. The various parts, field coils armature, armature coils, yoke, and a Bullock generator direct connected to a gas engine are illustrated, and an efficiency curve of a 200 KW. machine is included. There is a table of dimensions and code words.

Electrical Engineering in Sweden.—The Swedish State Railway Authorities have placed a contract with Messrs. Siemens & Halske for the establishment and equipment of electrical power stations at Abiskojokk and Kadeyokk, near the new railway between Gellivaia and the Norwegian frontier.

Infringement of Patent.—Judgment was given some days ago by Lord Justice Romer in the case of the British Motor Syndicate, Limited, and the Great Horseless Carriage Company, Limited, v. J. E. H. Andrew & Co., Limited, which was an appeal against a decision of Mr. Justice Kekewich. According to the *Times* report the plaintiffs, as the registered proprietors of letters patent (No. 5,479 of 1890) granted to Frederick William Lanchester for "improvements in gas motor engines," brought the action to restrain the defendants from infringing the patent. Mr. Justice Kekewich held that there had been no infringement, and he dismissed the action with costs. The decision was based on the ground that the patentee had by his specification claimed only his main method of carrying out his invention, and not two subsidiary methods. The defendants had raised the other objections usual in patent cases, such as "disconformity," anticipation, and want of subject-matter. The plaintiffs appealed. Mr. Moulton, Q.C., Mr. T. Terrell, Q.C., and Mr. A. J. Walter were for the plaintiffs; Mr. Cripps, Q.C., and Mr. J. C. Graham were for the defendants. The appeal was heard in July, when the Court reserved their judgment. Last week the Court allowed the appeal. His Lordship discussed the nature of the subsidiary methods, and then proceeded to consider the points taken by the defendants. With regard to the point on which the defendants succeeded in the Court below, his Lordship said that it was too narrow a construction to be placed on the specification. The patentee in the body of the specification clearly referred to the subsidiary methods, and intended them to come within the scope of his invention. His Lordship added that the wording of the first claim covered the subsidiary methods. This objection, therefore, failed, as also did the contention founded upon it that there had been no infringement by the defendants, because in their machine the flame does not strike back in the precise way covered by the patentee's main method. His Lordship then discussed other objections taken by the defendants, all of which he overruled, and concluded that the plaintiffs are entitled to succeed. He granted an injunction restraining the defendants from further infringing the plaintiffs' patent, and ordered an inquiry as to damages. The plaintiffs were granted their costs here and in the Court below, including the costs of the particulars of breaches.

Recent Motor Wagon Trials at Liverpool.—It may be noted as a fact of some importance that the second series of trials of heavy traffic vehicles held at Liverpool early in August, included no vehicles except such as were steam-driven either by oil or coke fuel. It appears that the winner in the first series of tests in May, 1898, namely, the Leyland vehicle, only received a silver medal this year, the winning vehicle being in both classes a Thorneycroft vehicle from Chiswick. Progress has evidently been made, for the trials this year not only included the same routes of 30 miles each as the trials of last year, but also some special hill climbing and descending trials, comprising gradients as steep as 1 in 9 upon very rough paving. The larger Thorneycroft wagon is said to have done specially fine work with a full load of 6½ tons carried up and down hill on a rutted road. On the long distance runs also the Thorneycroft vehicles did well, averaging 5 miles per hour. It appears to us that the motor vehicle industry is now fairly established, and that very soon considerable numbers of vehicles will be seen at work. We also anticipate a considerable crop of very serious accidents. Without a horse in front to push a person out of the way, these heavy motor vehicles have their leading wheels well thrust out in front and absolutely devoid of safeguards of any sort. To be run over by a heavy motor car will be as bad as to be run over by an electric tramcar, yet the latter are compelled to provide safeguards and the former have absolutely nothing, and come quietly upon a foot passenger from unexpected quarters and in diagonal directions, whereas an electric car does run on a recognised track. The motor van, or vans, of Messrs. W. H. Smith & Son are particularly noticeable in London as presenting the dangerous appearance above noted, in conjunction, we may add, with not too careful driving. We certainly think wheel guards should be provided by compulsion. It would be easy to do this, and the absence of such guards will cause accidents that may give another set back to the motor-car industry, accidents which, in the mind of any sensible juryman would, we hope, exercise a salutary effect on the "damages," while a coroner's jury, in our opinion, would rightly give its verdict in a fatal accident as one of manslaughter against those responsible for the deficiency.

Water Level Indicators.—Messrs. John Hopkinson and Co., Limited, of Huddersfield, have recently published a treatise on the "Indication of Water Levels in Steam Boilers," having special reference to water gauges fitted with automatic valves. The liability of gauges to indicate false water levels is pointed out, and Hopkinson's patent "Absolute" water gauge is suggested as a means for preventing this. This gauge is described and beautifully illustrated in the list before us. A serious form of accident which may arise where gauge plugs are blown from the body of the gauge is mentioned, together with a suggested remedy against accidents arising from this cause. After 27 pages of matter of this description, which is accompanied with several sketches, a list of prices of the various sizes and patterns of water gauges is given.

Orders Revoked.—The Board of Trade have given notice that they have revoked the Waterford Electric Lighting Order, 1892, and the Kilkenny Electric Lighting Order, 1892.

Testing Batteries.—Messrs. Niblett & Sutherland, of Chandos Street, W.C., have recently introduced some new forms of portable storage testing batteries. A battery giving 500 volts was recently supplied to the Liverpool Corporation Tramways. A smaller set is the ordinary pattern testing battery which gives 100 volts. It is considered that to those who are accustomed to the ordinary forms of testing batteries the size and weight will come as a revelation. As an illustration of the current-giving capacity of the batteries, the 500-volt battery mentioned was tested and ran five 100-volt 16-c.p. lamps placed in series, fully incandescing them for some considerable time. The total weight of the battery in question is only 50 lbs, and it is quite portable and can be handled with ease. For convenience of recharging, every battery of this type is divided into two sections, and is so arranged that these two sections can be placed in parallel or in series by means of an ingenious switching device with which it is fitted. In the construction of these batteries no soldered or burnt lead connections are used between cell and cell, so that trouble from defective connections is entirely obviated, and as a mechanically solid disphragm is used as a separator, internal short circuits are prevented. The internal resistance is so small that, as has been previously stated, an 8 or even a 16-c.p. lamp can be run from them, thus rendering the batteries useful for making continuity tests as well as the usual insulation tests. The 100-volt battery only weighs 14 lbs., and when the two sections of the battery are placed in parallel it can readily be recharged through, say, an 8-c.p. lamp on a 100-volt circuit. It is obvious that anyone about to use this battery for a test would naturally insure its being full by previously giving it a recharge, but the local action in the cells is so small that the batteries have been known to hold their charge and give their full potential after standing idle for over a month. Messrs. Niblett & Sutherland have supplied quite a number of these batteries, ranging in voltage from 100 to 500 volts, to various corporations and central stations. Among these may be mentioned the Charing Cross and Strand Supply Company, the British Electric Traction Company, the British Insulated Wire Company, the Belfast Corporation, &c.

Tests of Electric Light Engines.—From copies of tests made at Morley, by Mr. Hammond, upon some non-condensing engines of Pollitt & Wigzell's make, and at Bath upon the same firm's condensing engines, in each case fly-wheel alternators being driven, we find the following results:—The non-condensing sets are 125 kw., with horizontal engines having high-pressure cylinders, 14 inches; low-pressure, 23½ inches; stroke, 30; speed, 100; pressure, 130 lbs. The cylinders are side by side with fly-wheel alternator between, Corliss valves with trip gear. The alternators generate at 2,000 to 2,200 volts, and are 13 feet diameter over poles, and weigh 10 tons. The efficiency is 82 per cent. The steam consumption was 35½ lbs. per kw.-hour average of the two sets. The running was perfectly steady without vibration, and the governing good. At Bath, the engines are vertical, with cylinders 17 inches and 34 inches by 30 inches stroke at 124 revolutions with 150 lbs. pressure, these also have Corliss valves with trip gear. The fly-wheel alternator is 15½ feet diameter over poles, and weighs 12 tons. The efficiency is 82 per cent., as at Morley, for the combined plant. The boilers are water-tube type. Water was measured in a tank, and showed 24 lbs. per kw.-hour for one set, and somewhat less for the other set, the i.h.p. averaging 480, and the steam per i.h.p.-hr. 14·45 lbs. The results of all these English engines are very good, better, we think, than are obtained with most of the foreign made engines so far sent to England. But we must not despise the foreign made engine. It has kept us going in England when our own makers have been too busy—too saucy, a steam user puts it—to give any attention to the would-be purchaser. Patriotism is a good virtue, but it is apt to wear thin when asked to wait a year for a small steam engine.

Trade Announcements.—Mr. Carl Quiltmann, electrical importer, has removed from 17, Jewin Crescent, E.C., to 3, Cloth Street, Aldersgate Street, E.C.

Messrs. Wm. Coates & Son, Limited, have opened premises at 5, Leinster Street, Dublin, as electrical engineers, contractors, &c., and have appointed Mr. Martin Olsson, A.M.I.E.E., resident engineer.

The "Vril" Launch.—On the occasion of the Prince of Wales's recent visit to Cowes, H.R.H. having heard of the merits of the "Vril" launch as supplied by Messrs. Laing, Wharton & Down, Limited, issued instructions for one of these boats to be submitted for his inspection. The launch, which was 28 feet in length, was sent to the Royal yacht *Osborne*, and the Prince then gave orders that it should cruise towards the *Meteor*, whither the Prince went in his steam launch, accompanied by the Duke of York, Admiral Stevenson, and Capt. Fortescue. The party then inspected the performance of the boat from the deck of the *Meteor*, and the Prince was so pleased with it, that he afterwards, together with the others, boarded the boat, and went for a cruise round the fleet. Subsequently the chief engineer of the *Osborne*, Mr. Babb, went on board the boat, and made some suggestions which will doubtless prove of considerable value. The Royal party afterwards expressed great pleasure at the trip.

Water-tube Boilers.—We understand that the patent rights outside the United States for the Morrin "Climax" water-tube boilers have been acquired by Messrs. B. R. Rowland & Co., of Exchange Street, Manchester, which firm is now manufacturing the "Climax" boiler in this country. It may be mentioned that seven of these boilers of 500-h.p. and two of 600-h.p. are used at the works of the People's Light and Power Company, New Jersey.

ELECTRIC LIGHTING NOTES.

Aberdeen.—The Harbour has been equipped with 60 arc lamps on posts 25 feet high and 40 yards apart, arranged on two circuits, as well as with three beacon lights, each consisting of four arcs on a post 80 feet high. The lamps and posts were supplied and erected by Messrs. Lucy & Co., Oxford, at a contract price of £2,110; the mains have been laid by the Corporation at a cost of £5,000. The annual cost is estimated at £1,700. It is expected that the supply will be begun in a few days.

Banbury.—The Council has referred to the General Purposes Committee a recommendation made by another Committee that the town clerk take steps to obtain a provisional order for electric lighting.

Barnstaple.—The Town Council has resolved to apply to the Board of Trade for a provisional order for electric lighting.

Bermondsey.—The Vestry clerk has issued a circular pointing out that the Vestry has obtained an Act of Parliament authorising the Vestry to supply electrical energy; the system decided upon is low tension continuous current.

Bridgend.—The intention of the Council to transfer its provisional order to the English Industrials, Limited, is filed in the usual way in the *London Gazette* for August 18th.

Brighton.—The Local Government Board has given its sanction to the loan of £64,000 for 24 years for purposes of electric lighting.

Chadderton.—The District Council is considering the question of obtaining powers for the electric lighting of the district.

Cleckheaton.—The District Council is taking steps towards obtaining a provisional order for electric lighting.

Colchester.—An inquiry was held on August 16th by Mr. E. S. Fawcett, for the Local Government Board, into the application of the Corporation for leave to borrow £6,500 for electric lighting; this is in addition to a loan of £14,900, sanctioned in February, 1897. The present plant is capable of supplying 4,250 8-c.p. lamps; the new machinery is to consist of a 350-h.p. engine, coupled to a Siemens dynamo.

Dewsbury.—At a meeting of the General Committee of the Co-operative Society last week, it was resolved that on account of the heavy charges for the supply of electricity by the Dewsbury Corporation, the time had arrived to put down a plant for the purpose of generating electricity on the premises. The society's electric lighting bill at the Central Stores for the year ending June last was no less a sum than £508! The society has at present about 1,100 lights at the Central Stores.

(*Continued on page* 321.)

WEST HAM ELECTRICITY WORKS.

The question of electric lighting in West Ham first assumed practical importance early in 1896; Mr. G. H. C. Risch was appointed electrical engineer by the Corporation, and prepared a scheme to cost £67,000. Mr. Risch, however, was obliged to resign his post six months later on account of ill-health, and Mr. J. J. Steinitz, then at Leicester, was appointed in his place. A new scheme was drawn up by Mr. Steinitz, and after a Local Government Board inquiry in November, 1896, a loan of £50,000 was authorised. Before the completion of the works further loans of about £14,400 were also sanctioned, for the lighting of public buildings and other purposes.

Supply was begun on December 10th, 1898, but it was immediately found that extensions were necessary, and a further expenditure of £51,000 was decided on. It was in connection with the contracts for these extensions that a difficulty occurred, which aroused the interest of the whole industry. The Corporation insisted on the insertion in the contracts of a so-called "fair wages" clause, which was, to use a Hibernicism, more fair to the workmen than to the employers; the contractors, Messrs. S. Z. de Ferranti, Limited, refused to accept these conditions, which constituted a subversion of the settlement arrived at as the result of the engineers' strike, and after a stiff fight Messrs. Ferranti gained their end. The present capacity of the plant is 700 KW., but so bright are the prospects of the undertaking, that two additional steam alternators of 2,400 KW. joint capacity were put in hand, and the sum of £29,000 was voted for extensions to the mains.

The generating station is situated close by the Abbey Mills pumping station, one mile from the Stratford division of the borough and two miles from the Canning Town district. The station was built by Messrs. Gregar & Sons, Stratford, under the supervision of Mr. J. G. Morley, deputy borough engineer, and includes, in addition to the electrical works, a large pumping station in connection with the sewerage system.

The electricity works comprises a dynamo and engine room, pump room, workshop, various offices and storerooms, drawing office (also used as testing room), and a share in the boiler house, which is common to the pumping and electricity departments. A neat telephone switchboard provides ready means of communication between the works and various Corporation offices in the borough.

The boiler house, 129 feet by 47 feet, contains at present nine Lancashire boilers, made by Messrs. Spurr, Inman and Co., Limited, of Wakefield, working at a pressure of 120 lbs. per square inch. Each boiler is 30 feet long, by 7 feet 6 inches in diameter, and is capable of evaporating 10,000 lbs. of water per hour. The boilers are fitted with automatic stokers made by Messrs. Bennis & Co., Limited, Bolton. These are fed by their patent chain conveyor and an elevator, which raises the coal from the coal stores through a height of about 60 feet. The coal is scattered by the stoker over the whole surface of the grate. The latter is of Messrs. Bennis's new compressed air type, in which air is blown into each bar with great force, ensuring perfect and smokeless combustion. The makers claim that by this means the nine boilers are enabled to do the work of 16 hand-fired boilers, while two men are able to attend to the whole range.

A Green's economiser, consisting of 384 tubes 4 inches in diameter by 9 feet long, is fitted in the main flue, with the usual bye-pass. The shaft is 150 feet high, 8 feet diameter inside, lined with firebrick to a height of 56 feet, and is much more handsome, or, rather, less unsightly, than such structures usually are.

As will be seen in our illustration of the boiler house, the conveyors are not quite complete. This explains the presence of the coal heaps. In future the coal, which is brought up the Channelsea River in barges, will be delivered direct into the underground coal stores by a steam crane on the wharf.

In addition to the boilers described above, the foundations are laid for three water-tube boilers, each capable of evaporating 15,000 lbs. of water per hour, which Messrs. Babcock & Wilcox, Limited, have in hand. These will be fitted with their patent chain grate stokers and superheaters. The same company, which supplied the whole of the steam and feed piping already installed, has also on order three of its patent purifiers; two sets of surface condensing plant of Messrs. W. H. Allen, Son & Co.'s manufacture, capable of dealing with 20,000 lbs. of steam per hour; two Weir feed pumps, and the necessary steam, exhaust, and feed pipes. There are at present in use two feed pumps of Messrs. G. and J. Weir's standard type which draw from a feed water tank, 4 feet by 6 feet by 22 feet, in the pump room, through coke filters, and deliver to the boilers through another filter under pressure. The pumps are of the vertical double acting type; the dimensions are 7 inches diameter, 18 inches stroke, and they are capable of discharging against a pressure of 180 lbs. per square inch. As the East London water is hard, an Artesian well has been sunk to a depth of 450 feet, and is now being tubed; an ample supply of water for condensing is obtained from the canal close by.

The pump room contains, in addition to the feed water tank, one of Messrs. W. H. Allen's surface condensers of the marine type, having a tube surface of 1,000 square feet, and capable of condensing 12,000 lbs. of steam per hour. The air and circulating pumps are built up with the condenser, as will be seen in our illustration of the set. The air pump is single acting, 16 inches diameter by 8 inches stroke; the circulating pump is double acting, 12½ inches diameter by 8 inches stroke. India-rubber valves are used. The pumps are driven by a vertical compound engine, 9 and 14 inches by 8 inches stroke, running at 120 revolutions per minute, with fly-wheel.

The steam pipes are of mild steel, duplicated as far as the engine room but single to the engines, and are fixed with the exhaust pipes beneath the floor of the engine room, which is of York stone carried on steel joists, and cellared 8 feet deep; by this means the pipes, steam traps, &c., are kept out of sight, while the electrical connections and the lower portions of the alternators are readily accessible. The steam traps are of the Geipel type, one to each set, and the separators by Messrs. Holden & Brooke, of Manchester.

The engine room is 82 feet long by 42 feet wide, and contains ample room for the additional machinery which is on order.

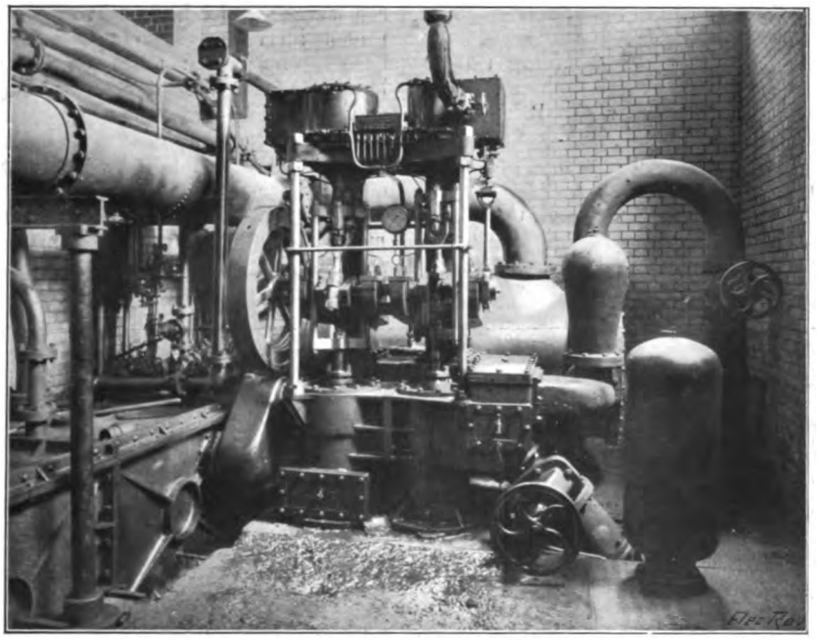
The generating plant consists of one 100-KW. and three 200-KW. steam alternators, made by Messrs. Ferranti, Limited; our bird's eye view shows the general arrangement of the plant, which is very compact, while another illustration includes the front view of one set and the back view of another. The engines are compound, with cranks at right angles, and are fitted with Ferranti's patent valve gear, with separate balanced steam and exhaust valves; the high pressure valve is controlled by the governor, while the low pressure cut-off can be varied by hand while the engine is running. The receiver, which forms the connection between the cylinders, is provided with a superheater fed with live steam; means are also provided for admitting live steam to the low pressure cylinder for starting. Forced lubrication is employed throughout, and the governor is provided with a separate oil pump; there is also an auxiliary oil pump, which may be worked by hand. The oil is circulated through a filter, which is seen in the illustration standing on the ground near each engine. Outside the main bearing, next the alternator, a roller bearing is fixed, the upward pressure of which is adjustable by means of coiled springs, to assist the main bearing; this fitting may also be used to lift the shaft and armature clear of the main bearing, should it be desired to remove the latter.

The alternators, which work at 2,100 volts, 250 revolutions per minute, are of the usual Ferranti air core type, the coils being mounted on porcelain insulators round the circumference of a fly-wheel about 6 feet in diameter, and weighing 9 or 10 tons. They run quite silently, and work perfectly in parallel, while they are able to withstand a heavy overload without overheating or any other injurious effects being met with. The two opposing sets of field magnets can be drawn back simultaneously by a right and left-hand screw at each end, the whole operation being performed by means of chain and worm gearing from one point. One terminal of the armature is connected with an insulated slip ring; the other is earthed to the frame, and the connection made by brushes bearing on the internal periphery of the fly-wheel. The exciters are of Messrs. Thos. Parker's hinged-pole type, with Eickemeyer windings, and are driven by ropes from the alternator shafts.

The switchboard is of Messrs. Ferranti's standard pattern,

Digitized by Google

and is at present arranged for four alternators and four feeders, two to Stratford and two to Canning Town. All the switches are in series with the inner conductor of the concentric cables, the outer being earthed. There are two Kelvin voltmeters, made by Messrs. White, of Glasgow, reading from 1,900 to 2,200 volts, and a Hartmann and Braun hot-wire voltmeter with open scale at 100 volts. A synchronising transformer is fixed over the switchboard. The ammeters are of Messrs. Ferranti's edgewise type, with ranges varying from 50 to 150 amperes. The exciting current is controlled by Siemens regulators, with Nalder ammeters. The small space occupied by the switchboard is well seen in our general view. A Thomson-Houston watt-hour meter is placed in series with each feeder.

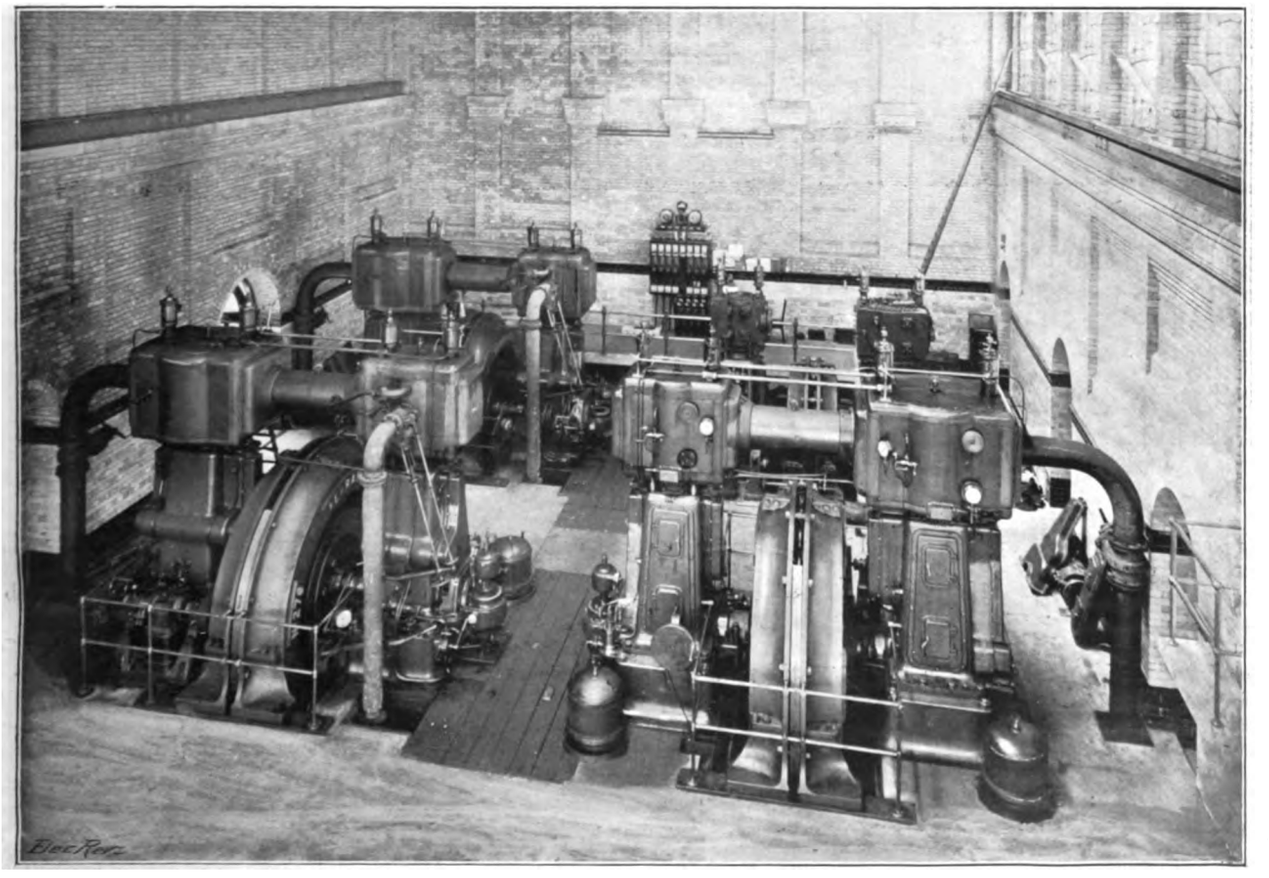


West Ham.—Condenser and Pumps.

A 10-ton travelling crane, made by Messrs. Taylor and Hubbard, of Leicester, traverses the whole length of the dynamo room.

Extreme care has been taken in the design of the sub-stations to ensure safety to the operators; the high pressure chamber is separate from the low pressure, and no one is allowed admission to the former except in the presence of the chief engineer or the foreman of mains.

The principal sub-station is in the basement of the Stratford Town Hall, and contains at present two 30-KW. transformers; two more are to be added shortly. There are two main feeders direct from the works to the sub-station; any transformer can be switched on either of these. A maximum demand indicator is placed in circuit with each transformer, and a Pitkin recording voltmeter is connected between the low pressure bus bars. The high pressure switchboard provides for five feeders to street transformer boxes, which can be switched on either of the main feeders; a Nalder ammeter is in series with each feeder. Two of these feeders run to the Empire Theatre, where 2,000 lamps are installed.



West Ham.—General View of Generating Plant, from Crane.

The distributing system is carried out by means of sub-stations and street transformer boxes; the whole of the latter, and the switching gear in the sub-stations, were made by the Brush Electrical Engineering Company, Limited. All the conductors in the sub-station are painted, the inners red and the outers black, to distinguish them from one another.

The arc lighting switchboard is so arranged that it can

Digitized by Google

be operated from the low pressure chamber, by means of insulated handles passing through the wall; there are six arc circuits, feeding about 60 lamps in all. A Shallenberger meter is placed in each circuit.

The sub-station at the Public Hall, Canning Town, is generally similar to the one described above, but has only four arc circuits, feeding 30 lamps. There are three other sub-stations, which are supplied from the principal ones, and 15 street boxes of the Brush patent type, containing transformers of 15 to 30 KW.

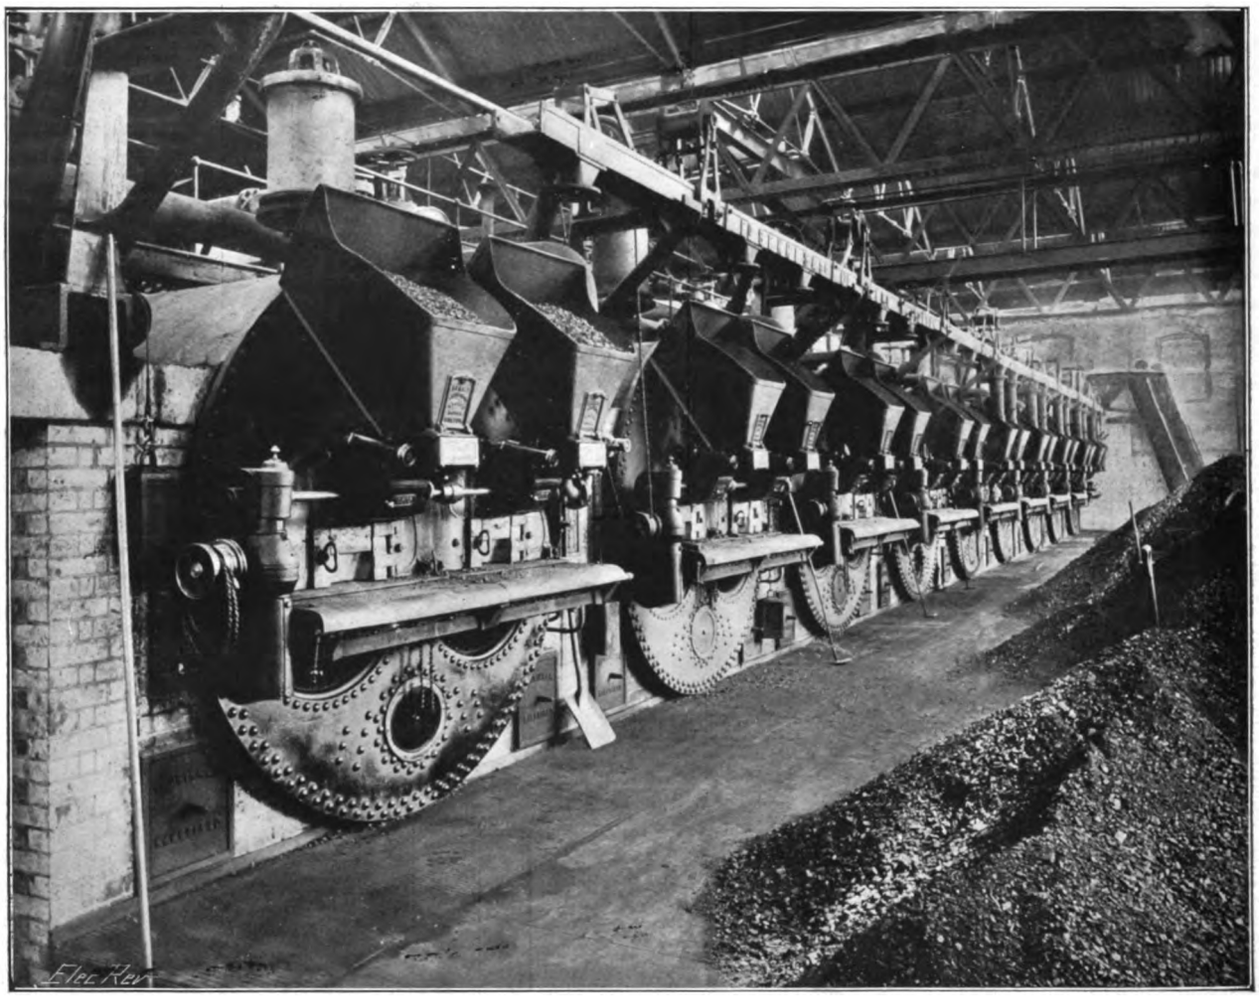
The whole of the cables were made by the British Insulated Wire Company, and are concentric, lead-covered and armoured. Both high and low pressure mains are laid direct in the ground in the same trench; to distinguish them, a copper wire is laid up with the armour of the high pressure cables. The main feeders to Stratford are 0·15 square inch, and to Canning Town 0·047 square inch. The low pressure distributors are mostly 0·15 square inch, the largest being 0·2 square inch.

For public lighting there are at present 88 arcs of the Thomson-Houston enclosed type, supplied by Messrs. Drake and Gorham, run in parallel across the high pressure mains, with a transformer in each post reducing the pressure from 2,000 to 83 volts. The number is to be increased by 100 lamps.

The low pressure supply is carried out on the two-wire system at 100 volts.

The charges for lighting are based on the Wright system, and are as follows:—For lighting, 7d. per unit for the first hour, and 3d. afterwards; for power, 5d. per unit for the first hour and 2d. afterwards. Thomson-Houston and Chamberlain & Hookham meters are used to measure the supply.

It seems to us to be a matter for regret that no attempt was made, so far as we are aware, to work the Corporation pumping machinery in conjunction with the electricity supply. It is commonplace nowadays to dwell on the advantages of a steady load; nevertheless, we rarely see a scheme laid out with a view to profiting by those advantages. Electricity supply for lighting purposes gives a daily load curve showing an extremely wide variation, which cannot be controlled. Pumping, however, is under the direct control of the engineers in charge, and by the addition of a reservoir it should be possible to regulate the load, so as to obtain, with the electricity load, a practically constant output. In the present instance the two departments are supplied, indeed, by the same boilers, but there is no provision to prevent overlapping of the loads. Single-phase synchronous motors to drive the pumps would have given perfect satisfaction, being under the direct supervision of the engineers; but, for that matter, there would have been no difficulty in the way of using two-phase alternators and motors, with benefit not only to the works, but to the power consumers also. There *may* have been insuperable difficulties in the way of such a scheme in this case, but we doubt it. As a case in point, we may cite the Bedford electricity works, where very similar conditions were met with; the sewage pumps are driven by alternate current motors, with the result that a considerable day load has been obtained.



West Ham.—Range of Lancashire Boilers.

In conclusion, we tender our thanks to Mr. Steinitz, who, we may add, has recently accepted the post of engineer to the Electrical Power Distributing Company; to Mr. J. K. Bock, the present borough electrical engineer, and the various contractors, for their assistance in the preparation of this article.

The British Association.—Wireless telegraphy will naturally be much in evidence at Dover during the meeting of the British Association. It is stated that, previous to his departure for America, Mr. Marconi will make all necessary arrangements for the demonstrations, which will be under the control of Prof. J. A. Fleming.

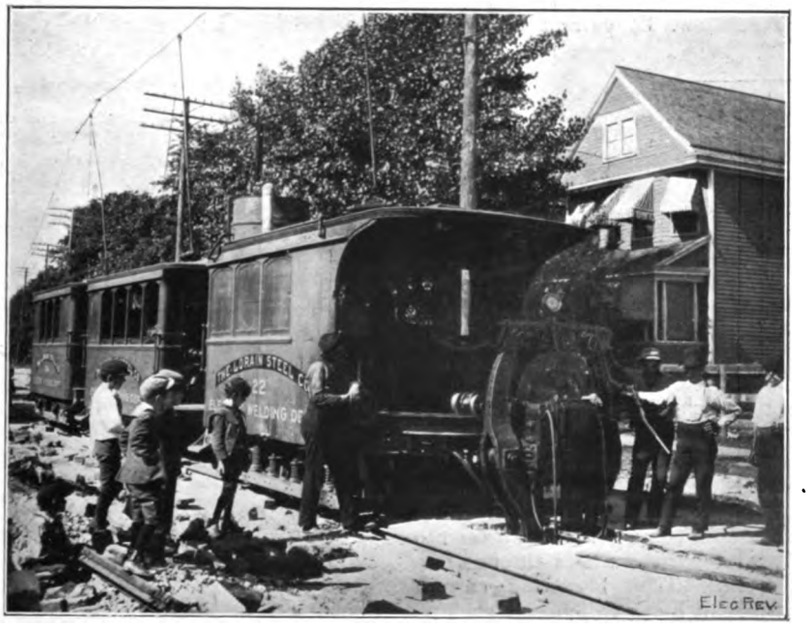
West Ham—View of Steam Alternators.

ELECTRIC WELDING TRAM-RAIL JOINTS.

[FROM OUR NIAGARA FALLS CORRESPONDENT.]

The Lorain Steel Company, of Lorain, Ohio, have one of their welding plants in operation in the city of Buffalo, where this year about 50 miles of track of the International Traction Company is to be welded. Of this length of track fully 25 miles will be of 60 feet 9 inches rails, with the ends left blank for the style of joint adopted. The Lorain Steel Company has succeeded to the business of the Johnson Company, and at present it has three plants in operation in as many cities in the United States. The process of rail welding has, it is felt, been perfected after years of experiment, and the results that are obtained are seemingly all that can be desired. As to the cost, it may be said that for the popular 9-inch girder rails, now so universally used, it is less than for any other style of so-called welded joint, while as a bond it is said to be the solution of the problem of electrolysis. In Buffalo the bar that is used for welding is 1 × 3 × 18 inches, and this joining of steel to steel, and the increased carrying capacity owing to the bars at the joints, results in the joint being the place of least resistance. The claim is made that a track electrically welded is of lower resistance than a rail itself.



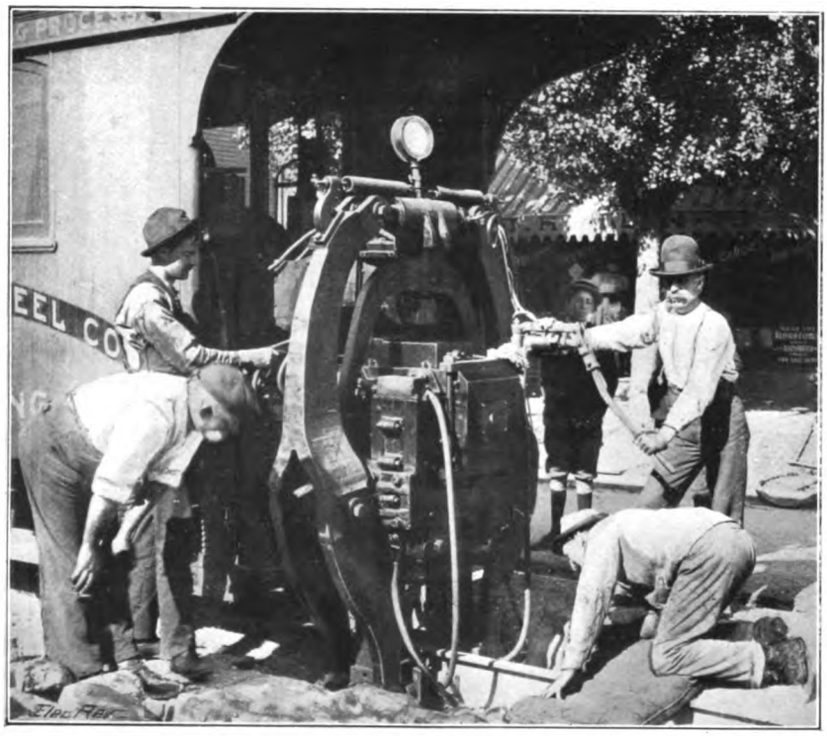
Electric Welding Tram-Rail Joints.—Machinery Cars.

The plant in operation in Buffalo consists of five cars. One of these is the sand blast car which runs in advance of the welding car, and prepares the joint. The other cars are the welding car, the transformer car, the motor and booster car, and a car that follows in the rear to smooth any rough places about the joint. In the adjoining illustration a train of three cars is shown, and these are moved along by power taken from the trolley service. The first car carries the welding apparatus, the car following has a transformer, and the rear car carries the booster and motor. The booster car weighs 34,000 lbs. A voltage of 500 is necessary for the

Digitized by Google

rotary transformer and apparatus. About 15 minutes are required to weld a joint, but the current is not in use all this time. In Buffalo the work of welding progressed night and day, there being no disturbance to residents of the street.

In streets where new track is laid the welding can be done before the pavement has been put down, or on old tracks, openings 17 by about 21 inches can be made in the pavement about the joint so that the welder can work. In other cases the pavement may be laid and openings of this size left until the welding machine has been applied. While at work the train attracts much attention, its operation and the results obtained being remarkable. After the welding bars are placed over the joint the jaws of the welder are applied to them, and a pressure of about 1,400 lbs. applied by means of a hydraulic jack connected to the upper end. The current is then turned on, and the metal heats brighter and brighter until the weld is completed, after which the current is turned off and the pressure increased to about 35 tons. While under this pressure the weld is allowed to cool, after which the car is moved back about 6 inches and the jaws applied to the other end of the bar, where the process is repeated. The other end is treated in the same manner. In other words the centre weld is made first and then the end welds. Artificial means of cooling are used, and as the bars cool they exert a powerful influence in bringing the rail ends close, so as to make a tight joint.



Electric Welding Tram-rail Joints.—Welder in Place.

The current for the operation of the plant is taken from the regular trolley wire service, and its application is well portrayed in the diagram given below. The current comes down

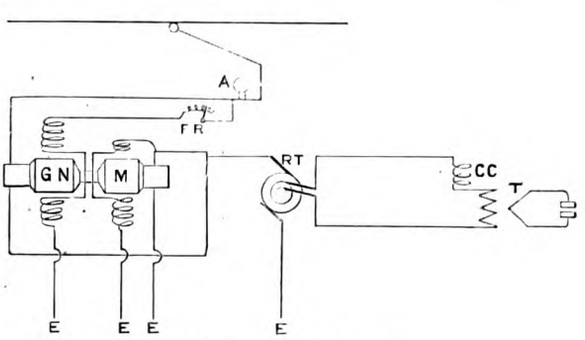


Diagram of Connections.

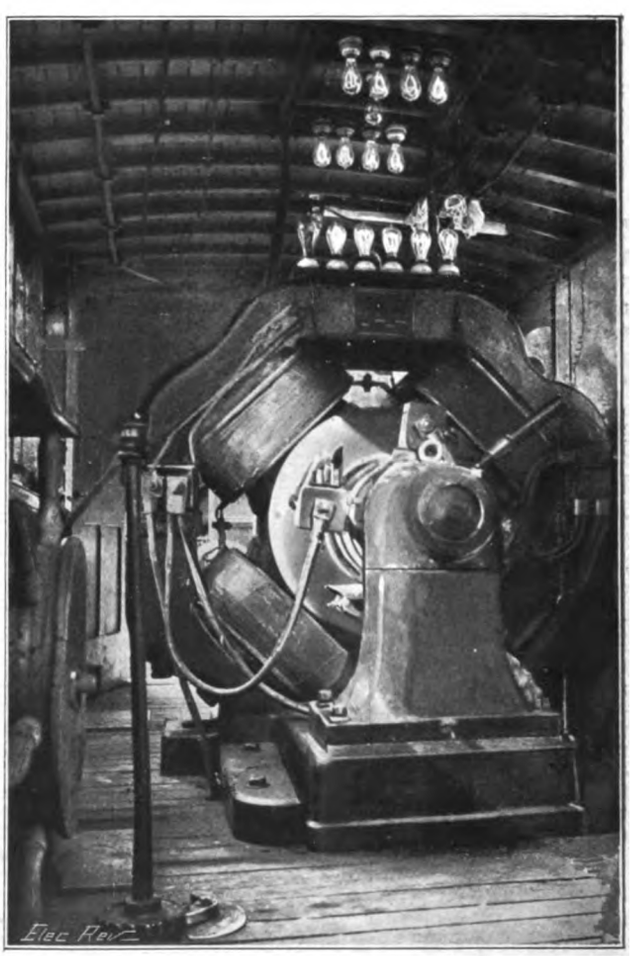
the trolley through the ammeter, A, and thence through a circuit breaker, which is not shown. It passes through the armature, G N, of generator end of booster, and then by one path through the armature and field of motor end of booster to earth. By the other path the current passes through the rotary transformer to earth. The alternating current from the rotary is led through a break switch and choking coil C, C, to the stationary transformer, T, between the welder jaws, the secondary of which consists, as shown, of one turn of copper. The terminals of the secondary are the clamps that grip the weld. In the diagram, F R represents a rheostat in the field circuit of the generator end of booster, by means of which it can be made to boost any amount desired to compensate for drop in the line voltage.

In reviewing this process one is naturally led to ask if heat will cause the rail to buckle, or cold cause the rail or weld to snap, but all these difficulties are overcome by the simple expedient of applying the immense pressure to the material during welding, therefore the length of a continuous rail made by this process is said to have no limit except that of the line itself. In summer, whatever expansion of the rail takes place is said to occur in the size, an effect not visible to the eye, but which, it is said, can be detected by careful measurements. In support of this claim as to the effect of cold in contracting the rails, it is said that given a continuous rail 10 miles long and one 100 yards long, under an equal degree of cold and



Electric Welding Tram-rail Joints.—Generator.

surrounded by the same paving, the contraction at the ends of the rails will be practically the same in inches.

Digitized by Google

By way of explanation it may be stated that the bars with which the welds are made have three bosses, this having been found preferable to a flat bar. Thus the boss is the only portion that comes in contact with the rail, and all the heat is concentrated at that point. It has been stated that artificial means are provided for cooling while under pressure, and at this time the comparatively colder portions of the bar about the boss serve to prevent the softer metal from spreading. As the pressure confines it there is practically no opportunity for coarse crystallization, and the effect obtained is identical with that of hammering the steel.

The Lorain Steel Company gives due credit to Mr. A. J. Moxham for the perseverance that has led to the triumph and success of the welding process.

ELECTRIC LIGHTING NOTES.

(*Continued from page* 315.)

Dingwall.—At the last Council meeting it was stated that with reference to the electric lighting of the burgh, the Council had signed an arrangement with Mr. Yorke, electrical engineer, binding the Council for 12 months not to entertain any other scheme. The 12 months were now up, and he asked what was to be done. The delay was caused by the fact that the Countess of Cromartie, not having attained her majority, was not in a position to grant water to them in perpetuity. The Countess being now of age, the Council could get on with the scheme.

Dumfries.—The Provisional Order Bill has received the Royal assent, and the Town Council is now in a position to proceed with the installation. Copies of the Act are being prepared for the use of councillors.

Eastbourne.—The electric lighting works are to be taken over by the Corporation on January 1st, and a resident engineer appointed at a salary of £300 a year. He will be required to devote the whole of his time to the duties of his office. Applications are to be sent in by September 1st.

Elland.—The District Council has appointed a committee to take steps to procure a provisional order for electric lighting.

Felixstowe.—The Felixstowe and Walton District Council has resolved to obtain a provisional order for electricity supply.

Fremantle (W.A.).—The harbour has been lighted with arc lamps.

Glasgow.—At the meeting of the Council last week Bailie Maclay, in moving the adoption of the accounts of the electricity department, said it would be seen from the figures that at the end of last financial year, after providing sinking fund, writing off liberally for depreciation, and after paying interest on capital account, they had a balance on the right side of £1,940. He thought this was satisfactory, especially as they had passed through a very trying year. They had spent largely on capital account, and that capital had been to a large extent unproductive. They had spent £100,000 in laying down cables in the streets of the city. These were still unproductive, but they thought it better to go on with the work vigorously, so that when the new plant was in working order there should be no delay in consequence of there not being cables to carry the electric current. He was happy to say that during the past year the output of electric current had increased 36 per cent., the number of consumers 30 per cent., the number of 8-c.p. lamps by something like 17 per cent. They had laid throughout the city 18 miles of new feeders and 28 miles of distributing mains. In regard to street lighting, in the previous year they had 119 street lamps; last year the number was 227, or nearly double. These lamps did not yield much, because they were only used towards the close of the winter. This year they would be used at the beginning of the winter. The original charge for street lamps was £26; some little time ago they reduced it to £18. Now they had reduced it to £14 which he believed to be the lowest charge for a street lamp in Great Britain. They had done this to encourage street lighting, and he was pleased to learn that the Watching and Lighting Committee had considered this question, and were prepared to go on with an extensive system of electric lighting of the streets of the city. Bailie Maclay further stated that the roofs were now on the new works at Port Dundas, that they had four new engines with dynamos coupled, and that they would be in full working order against the beginning of this winter. They were making great progress with the buildings on the south side of the river, and they had a large amount of plant on order both for Port Dundas and also for Pollokshaws Road station.—Mr. D. M. Stevenson said the interest on loans amounted to over £7,000, and of that £3,000 was on unproductive capital expenditure. He trusted that the Council would support him in getting a clause put into the next Omnibus Bill to be promoted in Parliament to place the interest on unproductive works to the capital account.—The accounts were approved.

Godalming.—The proposal of the Council to transfer its provisional order to the Urban Electric Supply Company, Limited, is recorded in the *London Gazette* for August 18th.

Heckmondwike.—The District Council has agreed to apply for sanction to borrow £14,000 for electric lighting purposes.

India.—The Indo-European Telegraph Company's offices at Kurrachee are to be lighted by electricity, an 8-H.P. Hornsby-Ackroyd oil engine and dynamo being installed for the purpose.

London.—Paddington Chapel, which is under reconstruction, is being lighted throughout by electricity and ventilated by means of motor fans. The contract has been entrusted to Messrs. Palmer & Watson, of Charing Cross Road, W.C.

The electric light has superseded gas at the Foundling Hospital, Guildford Street, in all parts of the building, including the chapel.

Lynn.—The electricity works is now almost complete, and the theatre supply has already been begun, as well as that of the Town Hall.

Montrose.—The Town Council has given its sanction to the contract between the Angus Electric Light Company, Limited, and Messrs. Edmundson's Electricity Corporation, Limited; the capital to be expended amounts to £15,000, which, in the opinion of Mr. W. Lackie, the Council's electrical adviser, is fair and reasonable.

Newbury.—We think that the Board of Trade's attention should be called to the recent decision of the Newbury Council not to proceed with a municipal lighting plant, yet to refuse the sale of the provisional order to the Electrical Power Distribution Company, to English Industrials, Limited, or to any other company that may express willingness to take the matter up. Furthermore, any application which may be made for a license or provisional order will be opposed. We have no doubt that at the proper time these companies or others will ensure an alteration in this state of affairs being brought about. During the past few weeks the Board of Trade has issued several notices of revocation of orders, and where, as at Newbury, a municipal authority has distinctly stated that it will not carry out the work itself, there seems to be no reason why an order obtained in 1892 for the execution of certain powers within two years should be in existence any longer. Revocation seems to be urgently called for at Newbury. Under the Board's extension grant the order expires within the next six months, but even that seems to us a needless delay after the matter has been shelved so long.

Paisley.—Although the electric lighting scheme for the burgh is not yet completed, so many orders for the new light have been received that the Electric Lighting Committee has asked the Town Council for powers to extend the machinery already placed in the works at Blackhill.

Penarth.—The District Council has yielded to the request of the Electrical Power Distribution Company for an extension of the time before purchase, and has increased the limit from 15 to 38 years.

Penzance.—The Town Council has decided to proceed with the application for a provisional order under the Electric Lighting Acts. The borough surveyor, Mr. Latham, suggests that the losses of the first three years, estimated at £4,150, should be provided for in the loan to be raised, and made part of the capital cost of the undertaking. In eight years he anticipates that the demand will reach 200,000 KW.-hours, and that there will be a profit of £1,000 at least on the working.

Pontefract.—The Guardians have been advertising for an electrical engineer to advise *re* an electric lighting scheme for the Union Workhouse and premises.

Portsmouth.—Last week, in connection with their summer excursion here, a party of the Institution of Junior Engineers visited the Corporation electricity works, and was shown round by Mr. Price, the superintendent.

Sheldon.—The District Council has resolved that Messrs. Hancock & Dykes be employed to make a survey of the district, and report on its suitability for the purpose of electric lighting, this firm having offered to send an expert for the sum of £25.

Walker.—Application has been made to the Estate and Property Committee of the Newcastle Corporation by the Walker authorities for the erection of a power station to generate electricity.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Barcelona.—The directors of the Barcelona Tramways Company, Limited, report for the year ended December 31st that the receipts for 12 months were £62,255, against £73,043. The gross profit on working was £8,081, against £12,064. The falling off in traffic receipts was due to a variety of causes, chief among which were the interruption to traffic occasioned by the change of traction, the depression caused by the late war, and the stoppage of streets by the extensive system of municipal drainage works. The increase in traffic receipts to date in 1899 has already covered the total decrease of the year 1898, although the electric traction has only gradually come into working and has still to be extended to a small portion of the system.

Digitized by Google

Blackpool.—A serious accident happened on the Blackpool and Fleetwood tramroad in Warbrick Road, Blackpool, on Saturday afternoon last. A milkman named Swift was driving a horse and float, and got into the lines. A tram came up, and before it could be stopped it smashed the milk cart to pieces. Swift was pitched out, and the wheels of the tram passed over his left arm. He was taken to the hospital, where the arm had to be amputated; he had previously lost the other. He had a serious scalp wound, and was then in a critical condition.

Bradford.—Complaints having been made as to the delay caused by the electric cars stopping at Southfield Lane, on the Great Horton section of the tramways, we learn from the *Bradford Observer* that this is unavoidable, because of the restrictions as to speed imposed by the Board of Trade since the unfortunate accident which took place there. It appears that by order of the Board, 35 minutes must be occupied in the down journey of 2¾ miles, and, however the drivers may check the speed, it is hardly possible to go slowly enough to avoid getting there too soon! Hence the wait, for the express purpose of losing time to comply with the order. We have heard of coaches being driven through Acts of Parliament; here is a tramcar standing still through a Board of Trade regulation! It is unnecessary to point out the absurdity of the order, which, however well-meant, is absolutely ineffective in limiting the actual speed at any moment.

It is now practically decided that communication shall be set up between the Leeds and Bradford tramway systems by means of a light railway from Thornbury to Stanningley, the total length being two miles. The line will be worked with steam by the Bradford Tramways and Omnibus Company until the expiration of the leases in January, 1903. The Leeds Corporation will probably extend one of its lines to meet the new line at Stanningley.

California.—A short description is given in the *Mechanical World* of a power transmission scheme which has been carried out at Mount Whitney, California. Water-power to the extent of 1,800 H.P. is obtained from the Kaweah River, whence the water is carried in a flume six miles long and a pipe line 3,300 feet long to the generating station. Electric power is generated and transmitted at 17,000 volts, three-phase, to Visalia, 29 miles away, and at 34,000 volts to Tulare and Porterville, 40 miles away. It is used chiefly for irrigation and lighting.

Dewsbury.—The Councils of the Spen Valley are troubled about the decision of the Light Railway Commissioners in favour of the British Electric Traction Company, and are discussing ways and means of reversing it. Some stress will probably be laid on a clause in the Dewsbury Improvement Act, 1884, giving the Corporation the right to refuse permission to place electrical apparatus along the streets of the borough. This clause, however, if the Board of Trade confirms the decision of the Commissioners, will *ipso facto* be repealed, and confirmed it will be, unless the five authorities concerned bury their differences and unite in opposition to the measure.

Driffield.—The District Council has been approached by the Drake & Gorham Electric Power and Traction Company, Limited, with a view to the construction of a light railway between Driffield and Beeford. A line has already been sanctioned from Beeford to Beverley, and it is said that the North-Eastern Railway has taken over the project.

Dublin.—The southern district of the Dublin United Tramways Company, which is operated entirely by electricity, shows for the first half of 1899 an increased net profit of £4,600. the gross revenue increased 50 per cent. in the past year, and the net revenue rose from £6,200 to £16,200. Evidently the benefits of electric traction are not confined to the passengers—the shareholders also have reason to congratulate themselves. The Tramways Committee of the Corporation, however, in view of the unfortunate accidents which have occurred lately, has requested the company to instal a third man on each car to look after the trolley pole. We should anticipate a very different balance-sheet if this extraordinary request were complied with. There are more rational ways of dealing with the matter—detachable trolley heads, for instance.

Another accident has occurred due to the trolley jumping the trolley wire; the guard wire was broken, and a carman named J. Caffrey was struck by one of the falling ends and rather seriously injured.

Last week the Tramway Company made some trial journeys to Terenure and back with a number of electric tramcars. Special interest attached to this trip, as these cars were the first worked by the new power station at Ringsend, which is to take over the working of all the electric traction in Dublin. The trials were in every way satisfactory.

Eccles.—A conference is shortly to be held at Eccles between representatives of the various local authorities, to consider the project of the United Kingdom Electrical Tramway and Light Railway Syndicate, Limited, for light railways in the district.

Factory Driving.—Messrs. Waterlow & Layton's new factory in Clerkenwell has been equipped with a system of electrical power transmission by Messrs. Crampton & Co., of Norwich and Cambridge. The generating plant consists of a 50-H.P. gas engine and dynamo, which supplies both the lamps and the motors. Each machine is provided with a separate motor.

Greenock.—The Law and Finance Committee has decided to recommend the Police Board to make arrangements for leasing the burgh tramways as an electrical tramway, and that the Committee be instructed to draw up conditions upon which offers will be received.

Goods Traffic.—The Isle of Man Tramways Company has commenced a service of "Bonner" rail wagons, which can be drawn by horses on ordinary roads to collect goods, and are afterwards mounted on bogies running on the tramway lines for transport. In this way the goods are transmitted the whole distance without being re-handled.

Grimsby.—The Lighting and Tramways Committee has come to terms with the Grimsby Street Tramways Company for the renewal of road leases; various improvements are to be carried out, and electric power is to be supplied by the Corporation, which has the option of purchase at the end of 10 years.

Halifax.—The Tramways Committee has under consideration the choice of routes to Brighouse and other districts to which the tramway system is to be extended.

Hastings.—A mass meeting and procession is to be held early next month in support of the tramway movement at Hastings.

Huddersfield.—The City Borough Council of Huddersfield on August 16th appointed Mr. J. Williams to be charge-engineer at the electric supply station, and Mr. W. E. Warrilow to be electrician-in-charge.

The Tramways Committee have decided to extend their system of tramways (which will in part be converted to the electric trolley system) to Llaithwaite and Marsden and to Brighouse and Bailiff Bridge.

The borough accountant reported the cost of the various works in connection with the adoption of electric traction to be:—(*a*) Power station, £8,000; (*b*) equipment of power station with boilers, machinery, &c., £17,120; (*c*) equipment of Outlane section with cables, poles, &c, £5,374 2s. 4d.; (*d*) equipment of Marsden Road section, £2,331; (*e*) equipment of Longroyd Road section, £3,457; (*f*) electric cars, £11,500; total, £47,782 2s. 4d. This is the portion of the whole system to be carried out forthwith. The work is already commenced, and the construction is expected to occupy two years. The estimated life of the works is (*a*) 30 years, (*b*, *c*, *d*, *e*) 20 years, and (*f*) 15 years.

Italy.—An electric tramway has been completed and put in operation in the town of Como. The line, which is only about a mile long, has been constructed by the Helios Company, of Ehrenfeld, Germany, and will be extended later.

Kelso.—Proposals are on foot for the utilisation of the water-power of the Kelso flour mills for working tramways, electric lighting, and pumping the town's supply of water. At present, about 100 H.P. is available from the turbines.

"Let Glasgow Flourish!"—A deputation of gentlemen from Copenhagen visited Glasgow last week, for the purpose of inspecting the tramways and electric lighting of the city. This is rather a novelty—we are more accustomed to seeing *our* deputations cross the ocean, than to receive visits from abroad. Things are looking up!

Liverpool.—An exchange says that a start has now been made with the proposed electric tramways from Seaforth to Crosby. It is anticipated that the line will be completed before next Easter.

Mytholmroyd.—The District Council is endeavouring to induce the Halifax Town Council to include a branch line down Cragg Vale in the projected extensions of the electric tramways.

Newcastle.—On August 18th the Tramway Committee of the Corporation had before it the question of adopting some form of conduit or surface contact system in the centre of the city in connection with the general overhead or trolley system outside. After a long discussion it was agreed that the Council be recommended to apply the trolley system throughout, as in the opinion of the committee it would not be wise, in the present state of uncertainty as to the suitability of the conduit system, to lay down any system of the kind.

Oldham.—The town clerk reported to the Surveyor's and Tramways Committee on August 17th that the Tramway Bill had become an Act of Parliament, receiving the Royal assent on August 8th. The Tramways Committee intends to ask the Electric Light Committee to supply the power for the tramcars. It was decided that the resolution passed some time ago, adopting the trolley system, be presented to the next meeting of the Council. A complaint was made that power had not been obtained in the Bill, which has just received the Royal assent, to increase the number of double lines in the borough. It appears that when the measure was under consideration, it was authoritatively stated that they could not come nearer the footpath than 9 feet 6 inches from the outer rail, but members of the Committee have since observed in Leeds tramrails within a yard of the kerbstones. The only way to get over the difficulty now is by another Bill, which is a somewhat expensive proceeding.

Portsmouth.—Mr. A. Bannister, whose appointment as tramway engineer was recently recorded in our Traction Notes, has withdrawn his application, his present employers having made it to his advantage to remain at Norwich. The Tramways Committee has therefore recommended Mr. Rotter's application for acceptance, and the Council has approved of his appointment.

Printing Press Equipment.—According to the *Newspaper Owner*, the proprietors of the *Scotsman* have contracted with the Bullock Electric Company, Cincinnati, through their London agents, Messrs. Bergtheil & Young, for a complete equipment of electric motors for driving the new quadruple and four-reel presses which are now being built for them by Messrs. R. Hoe & Co., of

Digitized by Google

London and New York. The motors are of 50 H.P. each, and are interchangeable in all parts. This installation is part of the complete newspaper plant about to be placed in the new *Scotsman* offices now in course of erection in Edinburgh.

Rawdon.—At a meeting of the Joint Tramway Committee of the Horsforth, Rawdon and Yeadon District Councils, held at Rawdon last week, it was stated that, contrary to its original purpose, the Leeds Corporation was willing to extend the city tramways as far as Yeadon. The Horsforth members objected to the Leeds Corporation having anything to do with the scheme. The Joint Committee will confer with the committee of the Corporation on the subject.

Southend.—The Town Council has appointed a committee to carry out the Light Railways order. The question of electric lighting is to be considered in conjunction with that of traction.

Tees-side.—The returns for last week show that the Middlesbrough, Stockton and Thornaby electric tramways carried 275,000 people between the three towns; this enormous traffic was dealt with without a single accident, although 50 cars were running with a three-minute headway. The necessity of doubling the line between Middlesbrough and Thornaby has been clearly proved. Mr. Clifton Robinson himself took an active part in directing the traffic, and on one occasion was instrumental in preventing a serious collision.

Tunstall.—The District Council will oppose the application of the Potteries Extension Tramways Company for an extension of time to October 1st next for the completion of their lines so far as the application regards the sections from the Council's boundary in Scotia Road to the terminus at Goldenhill.

TELEGRAPH AND TELEPHONE NOTES.

Cable Communication with the West Indies.—As the Halifax and Bermudas and the Direct West India Cable Companies' cables terminate at Jamaica, the recent interruption of the connecting companies' cables between that island and Puertorico prevented the acceptance of messages for the West India islands east of Jamaica at the usual rates. The Halifax and Bermudas Company announces, however, that it has been advised by the West India and Panama Company of the repair of the broken cables, and that messages to the West Indies may be sent "*viâ* Bermuda," as before, at the usual charges.

Interruption of Australian Trunk Landline.—According to the *Sydney Morning Herald*, of 13th ult., "At half-past 3 o'clock this morning we received word from the Electric Telegraph Department that the overland line to Port Darwin was interrupted north of Powell's Creek. We are consequently without our cricket cable news giving the result of the third day's play in the match at Edgbaston, Birmingham, between the Australians and the Midland Counties Eleven, in which the game is at an interesting stage."

Natal Telephones.—The *British and South African Export Gazette* says that the estimates of the Natal Government for the year 1899-1900 include £2,700 for improvements in the telephone system, besides £4,480 for additional telephonic communication; £1,500 for the installation of electric light in Government buildings; and £1,120 for batteries, instruments and materials.

The Reduction of Rates to India.—We are glad to see that the leading journals in India are now interesting themselves in a movement, which we hope will prove to be of ultimate benefit, both to that empire and to this country. Although we have treated of this subject very frequently, and for several years, we cannot refrain from again calling attention to the heavy tax, by comparison so utterly inequitable, which is imposed on Indian commerce, and on those whose social relations with India, oblige them to telegraph, even at the present excessive rates. To be obliged to pay 4s. per word for a telegram between Bombay and London, is a serious matter; but this is all the more to be objected to when we know that a message in transit between England and Australia is carried for about 1s. 5d., over exactly the same distance (and entailing, if anything, less work), as that which costs 4s. per word to the persons who telegraph from India to England, or *vice versâ*. There is not the slightest doubt that the existing "joint-purse" system keeps the charge for telegrams to or from India at an exorbitant figure. We understand that the Indian Government purpose to make another attempt to procure a reduction; but stronger measures than banal protests at triennial conferences may be looked for. Although we do not see eye to eye with Mr. Henniker Heaton in his proposed methods of reforming this scandal, we cannot help being impressed by some of the arguments he advances in the following letter which appeared in the *Times* of last Tuesday:—

Osborne Villa, Carlsbad, Austria, August 19th, 1899.

Dear Lord George Hamilton,—The question of reducing the present high telegraph charges to India is, I know, engaging your attention. I beg that you will not come to any decision on the matter until you have heard Sir Edward Sassoon and myself. We take the ground that any subsidy given by the Indian Government will considerably hamper competition and block the way of really cheap telegraph rates to India, Australia, and the East for many years. I have shown in articles in the *Nineteenth Century* and in the *Times* that all that is necessary is to link up the present land lines in order to have sixpenny rates to India; I have pointed out that land lines can be constructed at a fourth of the cost and will carry five times more messages than cables; I have pointed out that to-day the cost of a telegram from St. Petersburg to Vladivostok, nearly 6,000 miles, is about 2½d. per word, whereas from London to India by land the charge is 4s. per word by the Indo-European Telegraph Company's lines; finally, I have indicated four different land routes to India where "linking up" can be effected. The only reply to these statements is that the Ameer of Afghanistan will not consent to our constructing a telegraph line into or through his territory. It appears incredible that the enlightened Ameer, who receives a very large sum of money every year, from England or India, in the shape of a subsidy, declines to allow us to construct a telegraph line. He is surely aware that a telegraph line will not steal even the air or injure him in any way. My information, however, is that the permission of the Ameer can be obtained. [A statement of mine (questioned by a correspondent of the *Times*) that the Ameer had allowed telegraph lines to be laid to Kandahar and Kabul is borne out by the enclosed map issued by the Eastern Telegraph Company, in which you will see such wires are duly marked.] At all events we (with your sanction) intend to make an effort through other agencies to get the Ameer's consent. Even if it cannot be obtained, there are three alternative lines open to us. You are aware that both the Eastern Telegraph Company, its joint purse partner the Indo-European Company, and the Imperial Telegraph Committee of the House of Commons recognise that it will take many millions of money to secure an entirely round the world all-British telegraph cable line. It was alleged by representatives of the first-named company that, as everything is disarranged in times of war, it is better to depend on fast cruisers than on cables, because it is impossible to patrol a cable 2,500 miles across the ocean. We send our English mails to India and Australia every week through two foreign countries, France and Italy; then why object to telegrams (98 years in 100 we are at peace) going through foreign countries? We are now struggling on behalf of the merchants, tenders, and social classes against a great monopoly—a monopoly condemned in the strongest terms by your colleagues. Our work will be seriously impeded and we shall be crippled for another generation if you give your sanction to a further subsidy to these cable companies.

I am your faithful servant,

J. Henniker Heaton.

Sydney Telephones.—Part of the telephone system of Sydney (N.S.W.) is being changed over to the metallic return method at a cost of about £30,000. This is a precautionary measure taken by the Post Office in view of the conversion of the tram system from steam to electrical working.

South African Telegraphs.—Dispatches from Cape Town to the daily press say that the Imperial telegraph line has been opened to Maseru, the capital of Basutoland.

The Telephone Service.—The Cardiff Chamber of Commerce is of opinion that the Government Telephones Bill "will be infinitely less satisfactory to the country than if arrangements had been made for placing the whole service under Post Office control." Cardiff delegates to the autumnal meeting of Associated Chambers at Belfast are to be asked to ascertain the feelings of other delegates on the matter, and to submit a resolution to the above effect if thought desirable.

The Postmaster-General having asked whether the Council proposes to renew its application for a licence to transact telephone exchange business, the Council has instructed the town clerk to make the necessary application.

Wireless Telegraphy.—A *Times* telegram from Odessa says that trials of Signor Marconi's wireless telegraphy will shortly be made between Sevastopol, Nikolaieff, and the Black Sea fleet.

CONTRACTS OPEN AND CLOSED.

OPEN.

Barnsley.—September 16th. Tenders are wanted for electric light wiring and fittings at the Harvey Institute, Eldon Street, for about 700 lights. See "Official Notices" August 18th.

Digitized by Google

Battersea.—August 31st. The Vestry wants tenders for an overhead travelling crane (hand or electric), and batteries for the electricity works. See "Official Notices" July 7th.

Battersea.—August 31st. The Vestry wants tenders for steam pipes, pumps, condensers, economiser, tools, &c., also switchboard and booster. Specifications at the office of Prof. Kennedy, 17, Victoria Street, S.W. See "Official Notices" July 28th

Brighton.—August 30th. The Borough Council wants tenders for the installation of a system of telephonic intercommunication between the various offices of the Town Hall. Specification, &c., from the office of the borough engineer, Town Hall.

Carlisle.—September 11th. The Corporation wants tenders for extension to steam, drain, and feed pipes, feed pump, and extension of economiser at the electricity works. See "Official Notices" August 18th.

Devonport.—August 31st. The District Tramways Company invites tenders for the following contracts: Permanent way, road bed, paving and bonding of about 4½ miles of double line, overhead construction for about 4½ miles of route. See "Official Notices" August 11th.

East Ham.—September 9th. The Urban District Council wants tenders for combined electric light and traction plant, engines, generators, overhead line equipment, cars, switchboard, arc lamps, &c., water-tube boilers, condensers, and other steam plant, electric light cable. Mr. W. C. Ullmann, The Limes, White Post Lane, East Ham, is the Council's electrical engineer. See "Official Notices" August 4th.

Germany.—September 20th. Tenders are being invited until September 20th by the Cotton Wool Exchange authorities in Bremen for a complete installation of electric lighting in the new Exchange. Tenders are to be sent to Das Banbureau für die Bremer Baumvoll börse la Dechanatstrasse, Bremen, whence particulars may be obtained.

Hackney.—September 12th. The Vestry wants tenders for four sets of direct current steam dynamos (either high or low speed). See "Official Notices" August 11th.

Heckmondwike.—September 20th. The District Council wants tenders for the supply of water-tube boilers, economiser, pipe work, steam dynamos and motor boosters, accumulators, switchboard work, travelling crane, mains, arc lamps and posts, and station lighting. See "Official Notices" this week.

Ilfracombe.—September 25th. The District Council wants tenders for boiler plant, engine plant, dynamos, condensers, switchboard, mains, lamp-posts, accumulators, meters, crane, buildings, &c. See "Official Notices" August 18th.

Ingleton.—The Ingleton Electric Light and Power Company wants tenders for the supply of dynamos, switchboards, batteries, and wiring. See "Official Notices" August 4th.

Leeds.—August 30th. The Tramways Committee wants tenders for the electric lighting of the car sheds, Kirkstall Road. See "Official Notices" August 18th.

Luton.—September 22nd. The Council wants tenders for boilers, superheaters, engines, dynamos, switchboard, steam and other piping, batteries, street conduits, boxes, feeders, arc lamps and posts, and various other plant and machinery for the electric lighting installation. See "Official Notices" this week.

Malmo.—September 1st. The Gas Works' directors want tenders for the erection of electricity works for the city. Particulars on application to the clerk of the Gas Works (deposit 12s).

Moscow.—*Commercial Intelligence* says that next month electrical engineers and contractors will be invited to compete for the electric railway for Moscow. The contract will probably require an expenditure of about 20,000,000 roubles.

Perth.—August 28th. The Commissioners want tenders for boilers, condensers, steam dynamos, switchboard, underground mains, and accessories. See "Official Notices" July 28th.

Poplar.—September 6th. The Guardians want tenders for high speed engine and dynamo, electric motors, Lancashire boilers, economiser, and other plant, as briefly particularised in our "Official Notices" August 18th. Mr. Warden-Stevens, the consulting engineer, asks us to notify that Section L., Steam Jet Plant, relates to ejector condensers, jet pumps, and injectors; and Section M., Auxiliary Pumping Plant, to air compressors, centrifugal pumps, and three-throw pumps.

Portugal.—September 6th. Tenders are being invited by the municipal authorities of Cascaes, Portugal, for the concession for the electric lighting of the town.

St. Annes-on-the-Sea.—September 11th. The Council wants tenders for high speed engines, continuous current dynamos, and balancing booster, for electric lighting. See "Official Notices" August 18th.

Southport.—The Corporation wants tenders for the supply and laying of tram rails, points, crossings, bonding, permanent way; also overhead equipment, including poles, wires, &c. See "Official Notices" August 11th.

Sunderland.—The Corporation wants tenders for four 270-kw. three-crank direct current steam dynamos, and two surface condensers and cooling tower. See "Official Notices" August 18th.

Sydney (N.S.W.).—November 3rd. The Municipal Council of Sydney is inviting tenders for the construction and erection of a refuse destructor for treating 60 tons of refuse per day (24 hours).

CLOSED.

Belfast.—Messrs. Wimshurst, Hollick & Co., are to convert a 2-ton jib crane from steam to electric power for the Belfast Harbour Commissioners.

Brighouse.—The Council has given a contract (£329) to Mr. T. H. Churton, of Leeds, for electric lighting plant for the sewage disposal works at Cooper Bridge.

Glasgow.—In addition to the recommendation that the contract for main engines be given to Messrs. Allis, the Tramways Committee also recommended that the following tenders should be accepted, the whole sum involved, including that of the main engines, being £253,653 13s.:—

	£	s.
Auxiliary engines—E. P. Allis Company	8,375	7
Exciter engines—W. H. Allen, Son & Co.	3,054	0
Boilers—Babcock & Wilcox Company, Limited	21,280	0
Three-phase generators—British Thomson-Houston Company, Limited	25,670	0
Auxiliary generators—British Thomson-Houston Company, Limited	5,348	10
Exciter generators—British Thomson-Houston Company, Limited, London	1,711	0
Transformers—Westinghouse Electric Company, Limited, London	34,420	0
Rotary converters and boosters—Westinghouse Electric Company, Limited, London	39,215	16

Grimsby.—The Corporation Special Committee last week considered the tenders for the supply of machinery and plant for the electric lighting scheme. Seven tenders were sent in for the boilers, and that of Messrs. Anderton & Co., of Accrington, was accepted. Nine tenders were submitted for the engines and dynamos, Messrs. Mather & Platt being successful. The Tudor Accumulator Company obtained the contract for the batteries in competition with six other firms, and Messrs. Jas. White, Limited, were selected to supply the switchboards. The contract for the mains was secured by the British Insulated Wire Company. No tender was accepted for the supply of arc lamps, as Prof. Kennedy wished to test a certain make before advising the Corporation. The amount of the tenders is stated to exceed the original estimates. The explanation given for this is that the plans have been extended, and that the prices of materials have gone up 15 or 20 per cent. since the estimate was made.

Harrogate.—The Town Council has resolved to order the following plant:—A 600-H.P. engine with necessary pipes, &c., from Messrs. Maclaren, at £2,398; a 300-kw. alternator from Messrs. Ferranti, at £1,700 (less £215 for dayload plant returned); an ejector condenser from Messrs. Korting Brothers, at £550; an additional trunk main from the British Insulated Wire Company, for laying from the central station to the high pressure distributing centre. The surveyor is to prepare plans, &c., for the necessary buildings extensions for the above.

NOTES.

An Interesting Question.—The following query comes to hand as we go to press:—"Gentlemen,—I should be very much obliged if any of your readers will inform me why it is that alternating current motors spark so much more than do continuous current motors.—A. P."—[They don't.—Eds. Elec. Rev.]

The Renewable Lamp.—We are afraid we cannot congratulate the Renewable Lamp Company upon the line of action adopted by its advocates. We published a letter the week before last from "Charles Clifford," purporting to give us enlightenment regarding the lamp. In the usual way we placed our columns at Mr. Clifford's disposal, he having expressed a wish to go further into details. So far, no letter signed by Mr. Clifford is to hand, but we have, instead, received one giving an entirely different name and address, and signed "Lancastarian" (*sic*). The spelling of Mr. Clifford's letter was edited by us before publication, but in order that our readers may see for themselves how strikingly the errors of the two communications are in agreement, we print them both in parallel columns, the errors in each case being shown up distinctly. There is strong evidence of an attempt to disguise the handwriting, but the similarity is so palpable as not to require an expert to detect it. We think it will be clear that the writer of the two letters is the

Digitized by Google

same. Curiously, in one letter he is a "friend of the patentees," and in the other he assumes the *rôle* of "an impartial observer."

Re the Patent Renewable Glow Lamp.

Anent your remarks on above in last weeks issue of your enterprising journal, will you permit an old reader, and a friend of the patentees, & one cognisant of the incomparable advantages of which the above lamp is alone capable, to clear the ground of certain misapprehensions in this relation? First let me say that, had I space & your permission, to give in detail the unique capacity of this lamp to prolong its utility, at such a small outlay of material, time, labour, & money, & to explain how through the continuous interchangability of its filaments the thorough utilisation of all its material is effected to the utmost extent, the commercial value & complete public service claimed for this innovation by those of the highest repute & honour as practical experts who have submitted it to the most crucial tests, would be so manifest that, even your hypercritical correspondent *"Experiments Docet"* would admit the justice of the claim that this lamp will not only be the salvation of the enclosed globe, but supplies the longfelt public want among consumers of the current, by revolutionising the present system of lamp replacements, & doing away with the practice of having new lamps, & paying full prices for same.

And so far from *efficency* being sacrificed for cheapness it will be found, by comparison, that it is the highest ever recorded so soon as the lamp is on the market.

Surely it must be a great commercial achievement in any industry to reduce maximum waste of material & labour, has instanced in the Glow Lamp Industry at present, where incomputable & broadcast waste of Glow Lamps takes place the moment the lamps at present in use, reach the end of their first, and only, life?

True, many have tried to solve the problem of interchangeability of filaments even Westinghouse with his glass stopper, &c., how impracticable these devices were doubtless you are aware sir, but none hit upon the simple design of a tubular neck & expeditious method of exhanging filaments devised by C. Howard.

Depend upon it, Sir, if the advantages claimed were not genuine & had not been actually demonstrated neither Sir W. H. Preece, nor Major Cardews names would have been on the front page of the prospectus to bear testimony to the same, neither would Mr. Jacob Atherton of The British Insulated Wire Co., a most successful Compy, been identified with it unless it was the inimitable lamp the inventor asserts it to be. The economy claimed will on comparison be found to be actual and enduring, & be assured that its come to stay, despite *"Experiments Docet,"* whose friends will find shortly that their large stock of lamps &c. &c. are *obselete* and unsaleable. Without attempting to answer his assertions let me say that, all his objections have no relation, or bearing, to the above lamp, & proves conclusively "how little" he knows of the invention. In conclusion, let me add that (1) the Compy only claim to renew their own lamps, it is impossible to renew any other, (2) The filaments are of that peculiar kind that the bulbs are free from deposited carbon, (3) The glass too is unique & manner of opening, & fusing, so practicable that breakages will be very rare. (4) The detachable socket as withstood the most severe tests & is a perfect success & will admit of being used perpetually. (5) In all other lamp factories there is a certain loss of between 25 & 30 % on lamps made, through some non-glowing defect, broken filaments &c., in the manufacture of this lamp such loss will be unknown, has the least, or most serious, defect can be at once rectified by opening at neck where renewal of filaments takes place. That the economising & prolonging utility of this lamp is without parallel in this Electrical age, goes without saying, & consumers will ere long have the *oppertunity of verifieing.*

I could add to what I've said, but for fear of incurring your displeasure Mr. Editor. Thanking you in anticipation of your inserting this, & apologising for its length I remain faithfully yours

CHARLES CLIFFORD.

Re "The Renewable Lamp."

Dear Sir,—May I draw your attention to the fact that you made a favourable allusion to the above in your January number of 1897? As an impartial observer, I would endorse all your correspondent, Mr. C. Clifford, claims for the above, because the said claims are endorsed by gentlemen whose names are beyond reproach, and whose capacity to judge of this new lamps amplified utility, and peculiar *efficency* cannot be doubted.

That a renewable lamp is a most desirable agent, & would prove a most economical boon, to consumers must be admitted even by such detractors as *"Experiments Docet,"* whose line of attack was most "Unenglish" to use the mildest term, especially in face of the support accorded this remarkable lamp by Sir W. H. Preece, Major Cardew, &c., &c.

I consider all credit and support is due to any inventor, who finally achieves what previous experts failed to accomplish, & it is the worst of form, and betokens a carping disposition to be in haste to damn anothers brainwork before understanding the essence, or basis, of the invention, and before the public have had an *oppertunity* of *verifieing.* Possibly *"Experiments Docet"* is in the lamp trade, and, as C. Clifford reminded him, is afraid of his stock becoming *obselete.*

One fact is clear, present Glow Lamps are out of date, from their powerlessness to prolong their utility after their first filaments have burnt out; the majority of them lack *efficincy* & uniformity, and although they claim to burn 1,000 hours they only burn about half this period, and then throw off that "red glare" which is so distressing to us poor observing consumers, yet so profitable to the supply companies.

I for one shall range myself under the testimony of the above universally known experts, & accord this renewable glow lamp a fair trial when I can purchase them, & I assure you, Sir, I shall be one of your first correspondents to report my experiance. Hoping I have not transgressed,

I remain yours obediently,

LANCASTARIAN.

Electric Power at Niagara.—Prof. George Forbes has written the following interesting letter to the *Times*:—

SIR,—It was with unmixed pleasure that I have been able to pay a long-promised visit to Mr. W. B. Rankine, one of the vice-presidents of the Niagara Falls Company, to see how the commercial developments at Niagara were progressing; and I believe that a concise statement may be of interest to your readers. In June, 1892, and again in December, 1894, when the first works were nearing completion, I gave the *Times* some account of what was being done, and since then the public has taken much interest in similar electric developments of water-powers.

It is four years and a half since I was last here, and the first thing to strike one is the great number of enormous new factories which have been established on the company's land. Nearly every one of these consumes a very large amount of power, as is shown by the following statement, which anyone can verify, showing the names of the factories and the amount of power used in each:—

	H.P.
International Paper Company	7,200
Pittsburg Reduction Company (aluminium)... ...	3,050
Carborundum Company...	1,000
Buffalo and Niagara Falls Electric Light Company...	500
Electro-Chemical Company (peroxide of sodium) ...	400
Buffalo and Niagara Falls Electric Railway	200
Niagara Falls and Suspension Bridge Railway ...	250
Buffalo and Lockport Electric Railway	350
Oldbury Electro-Chemical Company	1,000
Mathieson Alkali Works	2,000
Cataract Power and Conduit Company (Buffalo) ...	8,000
Tonawanda Power Company	500
Union Carbide (of Calcium) Company	10,000
Surface Coating Company (enamelling)	20
Niagara Development Company (workmen's dwellings)	75
Niagara Waterworks	45
Total	34,590

To these additions are to be made in October, and two new works, the Atchison Graphite Company and the Lead Reduction Company (Litharge), will be supplied, bringing the total up to 45,190 H.P. contracted for, bringing in an income of over £150,000. The operating expenses do not exceed £25,000 per annum.

This is a most interesting result in three ways—(1) It shows that the original promoters were right in believing that the locality, with cheap railway transport, was favourable; (2) it shows that the general plan of the works, by which any customer could have any kind of electric current he desired, has been appreciated; and (3) it gives an indication of the enormous strides which have been taken of late years in electro-chemical and metallurgical processes.

Regarding the machinery, the dynamos, which were totally new, not only in size but in their general design, never give the slightest trouble; and the transformers, ranging up to 2,500 H P, have answered their purpose perfectly, even with the low frequency of alternations, which was generally condemned by theorists when I introduced it, but which is recognised now by everyone at Niagara as contributing largely to the success of the scheme. The rotary transformers, for converting alternating into continuous current, which are used for nearly half of the power, gave some trouble at first, being the first which had ever been commercially used. But the difficulties have been successfully met. A good deal of the other machinery was of a new character and bold in design, but has generally worked well. The setting-up and working of the transmission line to Buffalo reminds one of the earlier electric light stations in the United States, but this is bound to be one of the most important applications in the future.

The general conclusion arrived at, after thoroughly inspecting everything under the best auspices, is that the boldness of the originators of the scheme has been justified, and that the wants of manufacturers who require power in any form can be supplied. It must be remembered, however, that much depended upon the favourable locality, and this warning may be given, that it would be rash to develop a large water-power in this way without demands for power. At the inception of all these schemes there is one thing more important than overcoming the engineering difficulties, and it consists in ensuring the support of those who require large quantities of power, electrical or mechanical.

GEORGE FORBES.

Niagara Falls, *August 4th.*

Appointment.—The Oldham Surveyor's and Tramways Committee received 17 applications for the appointment of an assistant to Mr. Pickering (surveyor) in connection with the tramway works. Mr. Harry Clegg, of the Sheffield City Surveyor's office, has been appointed.

Institution of Electrical Engineers.—The following notice has been issued by the Council:—

In accordance with the Standing Orders of the Council, papers offered to the Institution are, on receipt, submitted to Council referees for report. If subsequently accepted by the Council, they are either read and discussed at an ordinary general meeting, or are published as original communications in the *Journal*. The Council, subject to the usual conditions, offer the following premiums for the session 1899-1900:—For papers read before the Institution—The Institution Premium, value £25; the Paris Electrical Exhibition Premium, value £10; the Fahie Premium, value £10. For original communications, not read at a meeting, but published in the *Journal* of the Institution—One premium, value £10; one premium, value £5. The next award of the Willans Premium by the Institution of Electrical Engineers will be made in December, 1903, and all eligible papers read before the Institution from January, 1898, up to that date will then be taken into consideration.

The Council will be pleased to receive communications on the following or other suitable subjects:—

1. Best methods of generating steam and steam power for variable loads. 2. Comparison of double and triple-expansion engines for varying load conditions. 3. Automatic handling of fuel in power stations. 4. The present position and applicability of gas or oil engines for electrical power stations. 5. Description of plants for the utilisation of water or wind-power in the generation of electrical energy. 6. The present position and prospects of the application of liquid and of powdered fuel in electrical power stations. 7. The utilisation of blast-furnace gases or other waste products of manufactures in the generation of electricity. 8. The application of dust destructors to the generation of electricity. 9. Electric light and power station chimney shafts; specialities of their construction and equipment. 10. Experiences with vibration from electric light and power stations. 11. Bearings of shaft and shafting running at high speed. 12. Improvements in dynamos. 13. Comparison of speed and cost of dynamos. 14. Comparison of single and multiple central stations. 15. The wholesale supply of electricity to towns and factories from centres where very large generating units are employed. 16. The distribution of electrical energy from a distant generating station through districts served from a different source of supply, or under a separate local authority. 17. Examination of relative advantages and disadvantages of direct current and alternate current transmission. 18. Examination of relative advantages and disadvantages of two-phase and three-phase transmission. 19. Methods of controlling speed of alternating current motors. 20. Practical methods of measurement in connection with polyphase distribution. 21. Methods for the conversion of direct current into alternate current. 22. Methods of providing for electrical supply during hours of small demand. 23. Utilisation of lighting plant for other work during the hours of small demand. 24. The electrical equipment of large blocks of offices in a city. 25. Description or comparison of systems of house wiring. 26. Economy of design in the manufacture of small electric fittings. 27. Portable electric lamps of the "safety" type, or otherwise. 28. Enclosed arc lamps. 29. Improvements in incandescent electric lamps. 30. Incandescence electric lamps with filaments other than pure carbon. 31. Application of electrical transmission in factories:—(*a*) Detailed description, giving sizes of motors and power provided. (*b*) Comparison of separate or combined direct and alternate current methods. (*c*) Combination of light and power for such purposes. 32. Electricity meters. 33. Description of electrical methods, or comparison of these with other methods, of propelling vehicles. 34. The supply of electrical energy for tramway purposes. 35. The use of electrical methods of traction on railways served by steam-driven locomotives. 36. The economy and design of electric elevators. 37. The design and economy of electrically-driven pumps. 38. The utilisation of electrical energy in mining. 39. The applications of electrical energy in warfare. 40. The use of electricity in the textile and other industries. 41. The application of electricity in musical instruments. 42. Electro-therapeutics. 43. The establishment of public time services by electricity. 44. Recent advances in telegraphy. 45. Applications of alternating currents in telegraphy. 46. The transmitting capacity and load factor of telegraph circuits. 47. Hertzian telegraphy. 48. Methods, in aerial telegraphy, of restricting signals to selected stations. 49. Recent improvements in telephony. 50. Descriptions of systems tending to simplify the interchange of telephonic communications. 51. The talking capacity and load factor of telephone circuits. 52. The application of electricity to the generation of heat for domestic purposes (cooking, ventilation, heating, &c.). 53. The construction and use of electric furnaces. 54. The application of electricity to the welding or annealing of metals. 55. The application of electrical heating methods in chemical or metallurgical operations. 56. The applications of electricity in metallurgical processes. 57. The applications of electrolysis in the smelting or refining of metals, or in the chemical industries. 58. The electrical equipment of chemical factories. 59. Chemical generators of electricity theoretically considered from a practical standpoint. 60. Improvements in and applications of primary batteries. 61. Examination of the present position of secondary batteries in electrical engineering. 62. Secondary batteries with plates other than lead. 63. The economic employment of thermo-generators. 64. Improvements in the apparatus for producing, and in the applications of, cathode and Röntgen rays. 65. The relative suitability and efficiency of the different materials available for any of the requirements of electrical engineering. 66. The electric strength of di-electrics. 67. Recent advance in the manufacture or use of insulating materials. 68. New insulating materials. 69. Electrical applications of aluminium, sodium, &c. 70. The electrical uses of the rarer metals. 71. The treatment, testing, specifications, or uses of iron or steel, or of iron alloys, for magnetic purposes. 72. The manufacture of permanent magnets. 73. The relation of chemical composition and physical condition to the electrical or magnetic properties of substances, considered in its bearing upon electrical engineering practice. 74. High resistance metals for instruments or resistance coils. 75. New resistance alloys. 76. The protection of laboratories and observatories against magnetic disturbances due to local causes. 77. Recent legislation in its relation to electrical undertakings. 78. The relations between electric lighting or power corporations and municipal authorities.

In Sheep's Clothing.—For many years we have directed the attention of our readers to the friendly financial relations which have existed between the Eastern Extension Telegraph Company and the Colonies from which this company derives the most considerable part of its income. Recent events have somewhat deranged this pleasant intimacy, and a policy of renunciation is now being adopted by those who were formerly the tyrants of the telegraphing public of Australasia. In the future there are to be no more subsidies. This announcement sounds well and reads well, but, in our opinion, any agreement which this cable company proposes to the Australian Governments requires the closest scrutiny. The Eastern group have only very recently abandoned a portion of their demand for subsidies of over £100,000 per annum for laying an "all-British" cable to Australia, with a branch to India *viâ* the Cape. Remembering the tenacity with which these companies have clung to State aid, as well as other points connected with their history, we decline to believe that this repentance is really heartfelt. Rather would we suggest that the Colonial Office should keep well advised of the arrangements concerning the the collection of telegrams which the Eastern Extension Telegraph Company are now attempting to conclude with some of the Australian Colonies. A joint-purse agreement between this company and South and West Australia at least might, were it considered among other conditions of Australian Federation, prove a serious difficulty in the way of the receipts of the Pacific cable, in the success of which the Colonial Office is interested. The following is from an Australian newspaper which has just come to hand:—

The Eastern Extension Cable Company has made an important proposition for an improved service between Australia and England. The company entirely waives its demand for a renewal of the subsidy of £32,400 per annum for 20 years in consideration of laying a cable from the Cape, and it does not now ask for a guarantee against competition, which it proposed in February, 1898. Further, in addition to providing a cable from the Cape all the way to Glenelg, *vid* Perth, the company will agree to at once reduce the tariff from 4s. 9d. to 4s. per word, and make a further reduction on a sliding scale as the traffic increases. In return for this the company only requires the same privilege in Perth, Adelaide, and Melbourne *as they have hitherto enjoyed in Great Britain, of directly distributing and collecting their international telegrams to and from the public.*

Fire in the Tape Shop at Messrs. Johnson and Phillips.—Early on Sunday morning last a fire broke out in the tape and insulation shop, which is one of the original buildings at Messrs. Johnson & Phillips. Several workmen were about at the time, and the hose was quickly connected up, but the fire spread so rapidly that the whole shop was soon in a blaze. Fortunately the wind was in the north-east, and so the general offices of the company escaped with only a few broken windows. We understand this particular department is very full of orders for the Eastern Telegraph Extension Company and Telegraph Construction and Maintenance Company, but we are sure that, with their usual energy, the firm will overcome the temporary difficulty, and within a few weeks' time be able to meet their most urgent orders. The building was not insured. Messrs. Johnson and Phillips write that the work in the electric light and power department and electric cable works will in no way be interfered with. By Tuesday they had been able to restart the greater portion of the machinery in the department concerned, and it was then hoped to have the rest of the plant in full work within the next 24 hours. The firm desires to thank its friends for the numerous sympathetic letters and offers of help received.

Personal.—As may be seen from our advertisement pages, Mr. Sydney F. Walker, who has for many years been connected with the electrical industry at Cardiff, is open to accept an engagement.

We learn that Mr. Charles Bright, F.R.S.E., is shortly to marry Miss Isabella Charlotte Gosling, of Hassobury, Essex, and Portland Place.

The freedom of the borough of Carnarvon is to be conferred upon Sir William Preece on Thursday, September 21st. A banquet follows the ceremony.

Negotiations with Prof. Röntgen, as to his acceptance of the Professorship at the University of Munich, are still proceeding.

The Trade Union Congress and the A.S.E.—The Amalgamated Society of Engineers has been suspended from the Trade Union Congress for two years. The reason is that when the smiths at Tyne Dock struck work because a poor boy, who had served a rather broken apprenticeship, was put to a fire, the A.S.E. allowed their members to take the strikers' places—a proceeding contrary to the rules of Trades Unions. One union must not thus interfere with another, however unjustifiable the strike may be. That the strike was unjustifiable we fully agree with Mr. Barnes, but, and we

Digitized by Google

confess to a strong bias against the ways of Mr. Barnes, we do not feel that Mr. Barnes's new-found zeal for the unfortunate and lowly placed is altogether what it appears on the surface. During the progress of the great strike of 1897, we frequently expressed our sympathy with the labourers of the engineer's shop, often men of infinitely better education than the tradesmen. At that time did we find any zeal in Barnes for an unfortunate class? Now he overflows with pity for one solitary individual who has not even the burden of a wife and family. We think there must be a nigger in the wood pile. It is matter of common knowledge that the general body of trades unions resented the high-handed action of the A.S.E. in 1897. The A.S.E. had waxed fat and gross, and would be a king among the unions, and this affair of a poor smith's apprentice boy seems to be merely the opportunity of getting even with the A.S.E. on the part of the other unions, while Mr. Barnes's sympathies with the boy, come in well to back up his conduct in letting his members fill up the places of strikers—also probably an aftermath of 1897, when Mr. Barnes did not feel he had the support he desired. Considering the way in which trades unionism has been carried on for some years, it is perhaps as well that they should fall out, by the way, amongst themselves. There is an old proverb which says that honest men get their own under certain circumstances. At the same time it is to be regretted that trades unionism should have fallen to so low an ebb. Trades unionism has its proper and legitimate functions, and employers are by no means immaculate, and because of this, is it the more important that the trades unions should so comport themselves as to retain the public sympathy. It is, after all, to public opinion—not to their war chest—that a trade union must look when it fights. If public opinion upholds it, no combination of employers can resist a demand by a trades union, and similarly, no secretary of a union, be he ten times less careful of funds than Mr. Barnes, could hope for success unless he had a much better excuse for war than that put forward to excuse the error of 1897. We little thought two years ago to be able to record to-day any expression of Mr. Barnes's feelings on behalf of the oppressed. It is possible Mr. Barnes has turned over a new leaf? If he has really done so, and honestly intends to live up to the blessed doctrine which he now professes, for his protests are almost paraphrases of our own expressions of two years ago, then we are willing to bury the hatchet. Unfortunately, however, Mr. Barnes claims retrospectively a position for the A.S.E. in which we cannot for a moment admit it took its stand. The A.S.E. cared for no one outside its own members, and not very much for them. The fight of 1897 was engineered by a clique for particular purposes, and the individual members had less say in the matter than a drummer boy in the army has over a plan of campaign.

Appointments Vacant.—An electrical assistant is wanted for the electrical engineering department at Hartley College, Southampton. See "Official Notices" this week.

The Wakefield Corporation wants a junior assistant electrical engineer and a dynamo and switchboard attendant. See "Official Notices" this week.

The King's Lynn Corporation want an assistant electrical engineer for the electricity works. See "Official Notices" this week.

Simla Water-Power Scheme.—A *Pall Mall* Simla correspondent writes with reference to the Simla water-power scheme which is shortly to be taken in hand by a London syndicate. It seems that at Bilaspur a cutting through a neck of land round which the river now makes a detour of some eight miles will give a head of 300 feet, with the whole volume of the Sutlej River behind it. The power, therefore, is practically unlimited. It is to be developed by turbines set at the bottom of the fall, and converted into electricity to be utilised partly on the Kangra Valley Railway, the North-Western, and partly on the Simla-Kalka Railway, the balance being taken on to Lahore and Simla for electric lighting and other purposes.

Electrician's Insulated Screwdriver.—The American *India-Rubber World* describes the screwdriver shown in the drawing, a patent for which has been applied for by Messrs. F. E. Ducharme & Son, of Shelbourne Falls, Mass. The handle of the tool is insulated with hard rubber, the latter

being made to surround entirely the portion of the blade in the wooden handle. The whole is said to be so well fitted, and the rubber is so fastened that no part can become loose or pull out from use. It was designed for use by electricians, though it is adapted for all purposes for which a screwdriver is desired, the cost being only a very little more than for the ordinary non-insulated screwdriver.

CITY NOTES.

Dublin United Tramways Company.

The directors' report, submitted to the shareholders at the Imperial Hotel, Dublin, on Tuesday last, says that the directors have declared a dividend at the rate of 6 per cent. per annum on the preference shares, and at the rate of 5 per cent. per annum, free of income-tax, on the fully paid ordinary shares, numbered 1 to 17,150, and at the same rate on the sums paid up on account of the fully paid ordinary shares, numbered 17,151 to 51,450. This dividend will absorb £29,401 4s. 7d., leaving a balance of £484 10s. 11d. to be carried to next account. Out of the profits of the half-year dividends have had to be provided on a considerable amount of capital which is not yet remunerative. The directors report that the reconstruction of the tramways, the laying of the underground conduits and cables, and the erection of the overhead electrical equipment throughout the whole system, are practically completed, and they expect that power will be available before the end of this month from the new generating station at Ringsend, to operate by electricity the remaining lines which are now worked by horses. Mr. William Anderson, the secretary and manager, having resigned these positions, has been co-opted to the vacancy in the board created by Dr. Carte's death, and appointed managing director. The positions held by Mr. Anderson have been filled by the appointment as secretary of Mr. R. S Tresilian, formerly assistant secretary, and as manager of Mr. C. W. Gordon, a gentleman of large experience in tramway management. Mr. Wm. M. Murphy has been elected chairman of the board of directors. The dividend warrants will be sent out on 31st inst.

The ordinary general meeting was held at Dublin on Tuesday, Mr. William Murphy presiding.

The Chairman, in moving the adoption of the report, said that as the result of the operations for the past half-year, they were enabled, after paying all the fixed charges, including 6 per cent. on the preference capital of £600,000, to repeat the dividend of 5 per cent. on the ordinary shares of the company. The secretary had calculated that not less than £385,000 of their capital expenditure in relation to the electric charges was unproductive during the past half-year. During the period the company's cars travelled 2,445,802 miles, carrying 16,851,309 passengers, on the three electrical lines in operation—namely, Donnybrook to Phœnix Park, Nelson's Pillar to Dalkey, and Nelson's Pillar to Dollymount. The total expenses were £23,308, while the amount earned was £45,471, showing that the working expenses were just 51 per cent. of the passenger receipts. He believed the change from horse-power to electricity would increase the profits threefold. In a few days the Rathmines line would be worked electrically, and in a couple of months or so the horse system of working their cars would be relegated to the domain of ancient history. Having referred to the authorisation by the Privy Council of some new lines of tramway in the city and suburbs, the chairman said the trolley scare got up by certain newspapers was really a clumsy piece of journalistic work. Nobody, he said, now paid any attention to the sensational statements "which have so often been found to be pure invention or gross exaggeration." The directors were fully alive to the necessity of taking every precaution that care and science could suggest for the safety of their passengers and the public, and they believed they had succeeded well having regard to the tens of thousands of miles the cars travelled and the millions of passengers they carried. Constant improvements were being made, the latest being a new trolley head, the invention of their electrical superintendent, Mr. Towell. He had been asked, with reference to the town clerk's letter, which had appeared in the newspapers, whether the Corporation had power to compel the company to put three men on each car. His answer was that they had not. The chairman mentioned that the directors intended to introduce a system of stopping the cars at fixed places (a plan which works well in Glasgow, Leeds, and elsewhere).

The report was adopted unanimously.

Digitized by Google

The Chloride Electrical Storage Syndicate, Limited.

The directors in their report for the year ending June 30th, 1899, say:—"During the year the business of the syndicate has continued to increase, as will be seen from the diagram which accompanies this report. In order to cope with the continuously increasing demand the works have been still further enlarged and considerable additions made to the plant. The ground lease of the land on which the works stand has also been purchased during the year. The users of the battery still continue to express their full confidence in its merits, and this is best evidenced by the large number of repeat orders which are constantly received. Many new customers have also been added both in this country and abroad. Since the date of last meeting the directors have entered into a revised arrangement with the Electric Storage Battery Company, of America, which they consider will be to the advantage of the syndicate. The balance-sheet, as required by the articles of association, is enclosed with this report, and from this it will be seen that the profits for the year, including the surplus on the sale of certain patents and shares, after providing for debenture interest, amount to £13,487 1s. 5d., which the directors consider satisfactory, especially when the large increase in the cost of raw material is taken into consideration. After writing off from several accounts £5,160 16s. 9d. (an amount which the directors think necessary) there remains a balance of £8,326 4s. 8d., to which must be added £2,903 5s. 10d. brought forward from last year, making £11,229 10s. 6d. After deducting the cumulative dividend of 7 per cent. up to June 30th, 1894, upon the "A" shares allotted prior to that date, paid by the directors in November, 1898, and March, 1899, the directors propose to carry forward the balance, out of which a dividend may be paid at their discretion. The first mortgage debentures have been paid off, and a fresh issue of £20,000 completed. The retiring director under the articles of association is Mr. A. R. Harvey, who, being eligible, offers himself for re-election. The auditors, Messrs. Parkinson, Mather & Co., also retire, and offer themselves for re-election.

The meeting is to be held at the Works, Clifton Junction, near Manchester, on Tuesday, August 29th.

The Brush Electrical Engineering Company, Limited.—The directors have decided, subject to audit, and after placing £5,000 to the depreciation reserve fund, to recommend payment of a dividend to the preference shareholders at the rate of 6 per cent. per annum for the half-year ended June, 1899, (making the full dividend of 6 per cent. on the preference shares for the year) and a dividend at the rate of 5 per cent. on the ordinary shares for the year, leaving a sum of about £5,000 to be carried forward to next account. The share transfer books of the company will be closed from August 28th, 1899, to September 8th, 1899, both inclusive.

British Westinghouse Electric and Manufacturing Company.—At an extraordinary general meeting of this company held at Cannon Street Hotel yesterday (Thursday), a resolution passed at a meeting held on August 9th, altering Article 83 with respects to powers for appointing directors, was confirmed. Mr. Benson presided.

Stock Exchange Notice.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Hampstead Electric Supply Company, Limited—13,334 ordinary shares of £5 each, and 13,334 5 per cent. preference shares of £5 each.

House-to-House Electric Light Company.—An extraordinary meeting of this company was held at Winchester House yesterday afternoon to confirm resolutions passed at a previous meeting altering the name of the company.

Nernst Lamp, Limited.—A meeting of this company was held on Wednesday at Winchester House to confirm the winding-up resolutions passed at the last meeting, and recorded in our issue of August 4th, page 203.

TRAFFIC RECEIPTS.

The Blackpool and Fleetwood Tramroad Company.—The receipts for the week ending August 19th, 1899, were £1,919 7s. 4d.; receipts for week ending August 19th, 1898, £1,295 18s. 5d.; aggregate for half-year to date, £9,900 11s. 4d.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending August 18th, 1899, were £3,484 14s. 2d.; corresponding period 1898, £3,941 4s. 2d.: decrease, £456 10s. 0d. Visit of Barnum and Bailey's Show three days last year.

The City and South London Railway Company.—The receipts for the week ending August 20th, 1899, were £1,080; week ending August 21st, 1898, £1,044; increase, £36. Total receipts for half-year, 1899, £7,746; total receipts corresponding period, 1898, £7,828, decrease, £82. Miles open, 3½.

The Dover Corporation Electric Tramways.—The receipts for the week ending August 19th, 1899, were £321 13s. 5d.; week ending August 20th, 1898, £272 15s. 11d.; increase, £48 17s. 6d. Total receipts to date, 1899, £6,141 4s. 3d.; corresponding period, 1898, £4,979 8s. 3d.; increase, £1,161 16s. 0d. Miles of track open, 1899, 8; 1898, 8. Car miles run, 1899, 4,916; 1898, 3,744. Number of cars, 1899, 12; 1898, 10.

The Liverpool Overhead Railway Company.—The receipts for the week ending August 20th, 1899, amounted to £1,695; corresponding week last year £1,664; increase, £31.

The Dublin United Tramways Company.—The receipts for the week ending Friday, August 18th, 1899, were as follows:—D. U. T. Co., horse cars, £2,944 19s. 10d.; ditto, electric cars, £1,316 2s. 8d.; D. S. D. Co., electric cars, £1,157 10s. 8d.; total, £4,718 12s. 4d.; corresponding week last year—D. U. T. Co., horse cars, £3 016 5s. 10d.; ditto, electric cars, £646 16s. 0d.; D. S. D. Co., electric cars, £1,218 14s. 1d.; total, £4,881 15s 11d.; decrease, £163 3s. 7d. Aggregate to date, £32 889 10s. 2d.; aggregate to date last year, £31,802 5s. 4d.; increase to date, £587 4s. 10d. Worked:—The mileage open is 18 miles electrically, 26 miles by horses, as against 12 miles electrically, and 30 miles by horses, for the corresponding period last year.

The South Staffordshire Tramways Company.—The receipts for week ending August 18th, 1899, were £712 13s. 1d.; aggregate receipts for 33 weeks, £21,667 4s. 0d.; week ending August 19th, 1898, £735 19s. 2d.; aggregate receipts for 33 weeks, £20,589 2s. 4d.

STOCKS AND SHARES.

Wednesday Evening.

While business still shows itself shy of returning to the electric market, a continuance of the firm tone upon which we commented last week is still the principal feature. Holders of Electricity Supply shares are recovering from their recent nervousness, and show a marked disinclination to accept any sort of a price which may be offered when they want to sell, although it was only a few weeks back that they were grateful to come across a buyer at all. The shares showing the biggest rise on the week are House-to-House and Westminsters, each of which is 10s. to the good, and the former company is finding supporters at last. There has been a fairly brisk demand for Edmundsons, and buyers have also come along for Charing Cross Preference, which, at the present price, yield about 3½ per cent. to the purchaser. A further call of 30 per cent. has been made upon County of London 4½ per cent. Debenture stock, and the price has fallen a point, some of the holders electing to sell their scrip rather than pay the instalment. The market for Citys is very quiet, but the shares have developed a stronger tone, and there are a few bears about in the market.

A correspondent asks us some questions about the Smithfield Electric, and as many of our readers are interested in this concern, we may here state that the price of the shares is 3¼—3⅜. They are much easier to buy than to sell—in fact, the last seller who appeared in the market only got £2 a share. Since then the price has improved a little, and the Debentures have also moved up to about 90. No official quotation exists for either description. We should not recommend the shares for an investment, and the price of the Debentures points conclusively to the fact that the security is not altogether "gilt edged."

The principal feature in the telegraph market is the advance which has taken place in the Anglo-American Telegraph Stocks. This is due mainly to the increased activity in the American railway market. A "Yankee boom" being invariably productive of good business to the Anglo-American companies. No alteration, however, has taken place in the prices of Direct United States or Commercial Cable stocks. Eastern Ordinary is once more on the up-grade, and it is understood that the company has benefitted, rather than the reverse, from the calamity in the West Indies.

The West Indian Telegraph stocks are all steady, but, of course, there is not much inducement to buy until it is known definitely how much damage has been done to the company's lines. A bull point, however, is afforded by the announcement that two of the companies have now restored their rates to the West Indies, which it is hoped will bring about some acquisition of fresh business. Globe Telegraph have recovered the 5s. which they shed a fortnight ago.

We have repeatedly called attention to the excellent prospects which appear to be in front of the Electrical Manufacturing Companies, and although the market in these is very restricted, there has of late been a distinct tendency to put prices better. This week it is Callender's which have risen, and the Preference are quoted 5⅞. Brush Electrical shares have also enjoyed some little popularity, and the ordinary have managed to attain the price of 2½ middle. The increased dividend is largely accountable for the rise. British Electric Traction are inclined to dulness, and the Preference have fallen ¼, despite the fact that the company has entered into negotiations with the Leamington and Warwick Tramways, which should prove remunerative to the former.

The chairman of the London General Omnibus Company in his speech at the meeting last week, threw out a most interesting hint with regard to the future traction to be adopted by the company, expressing his opinion that "electricity would come some day." Should any change be found conducive to the shareholders' interests, he added, the directors would not be long in making it.

Barcelona tramway shares remain at 12—14, although no dividend is forthcoming on them. Now that the whole of the company's lines, with a small exception, are being worked electrically, some return to prosperity may be anticipated. Buenos Ayres and Belgrano "A" Preference are unchanged at 4½, and the market for provincial trams is very quiet.

UNFAMILIAR APPARATUS.

The receipt of a large illustrated sheet of Blake's, of Accrington, hydraulic rams, brings to notice an unfamiliar appliance. Few know of the hydraulic ram, though there are considerable numbers in use. We believe the hydraulic ram was invented by Montgolfier. Its principle of action consists in allowing a considerable body of water to flow down hill in a pipe of some capacity and suddenly stopping the outlet. The descending water cannot be thus instantly checked, and its stored energy, being considerable, manifests itself as pressure, this being sufficient to open a small additional escape valve which communicates with an escape pipe up which a small quantity of the water is caused thereby to flow to a considerable height. The apparatus has no moving parts, except the large and small escape valves, the first of which is held open against the large flowing stream by a light spring or load, and closes when the decending stream attains such a velocity as to overcome the spring, while the second is kept shut by the pressure in the delivery pipe and only opens during the short period when the pressure in the outlet vessel is momentarily increased. Hydraulic rams are of two varieties; those in which part of the actuating water is delivered for use, and those in which an impure supply of water may be used to force a pure water up the delivery pipe. A ram may be counted upon for an efficiency of at least 50 per cent., and even 75 per cent. is claimed to be at times secured under favourable conditions. As rams call for no attention and will work continuously, it is surprising how a constant small supply aggregates during a 24 hours' day. Rams are made to give as much as 400,000 gallons per day, and rams are made that will force water as high as 800 feet. It is very much a question of proportion. To the engineer, the interest of the ram is that it can be employed in situations where any other form of water-raising apparatus would be much less suitable, and it can thus be conveniently used to force water from a distant stream to a steam-power station. As a rule, in this country a ram will be unaffected by weather. They are usually placed in a brick chamber, well protected by earth banking from frost, and their supply can generally be drawn from the stream at a protected point, sufficiently so to ensure constant working so long as there is a flow in the stream. We have ourselves known hydraulic rams to have been at work many weeks without even being seen during the time. We think station engineers might with advantage consider the question of using rams under certain circumstances.

CO-OPERATIVE PRODUCTION.

It is an easy matter for the working man to combine for purposes of purchasing and distributing goods. When he does so we do not find that he inquires too curiously into the origin of the goods he purchases nor as to whether they have been produced by sweated labour!—all he appears to care for is that the price shall be low and the quality high, and the bonus, or dividend, or surplus, call it what you will, shall be high. But co-operative production has far less attraction for him, and this was well brought out by Mr. Gerald Balfour when opening the Exhibition of the Labour Association for Promoting Co-operative Production on the 15th inst. From the tenour of Mr. Balfour's remarks, it would appear that he regarded the comparative failure of co-operative production as due to the fact that the co-operative societies, unlike the joint-stock company, did not employ the highest talent to be obtained, they did not pay the necessary salaries, and they did not invest the manager with the necessary supreme authority to command success. These necessary elements of success do not commend themselves to the workman who, as a small shareholder, is also, perhaps, a low-paid worker. He is apt to consider himself as badly treated if ordered about by the manager, who, perhaps, holds no shares. The so-called Co-operative Cotton Mills of Lancashire are often held up as examples of what can be done in the way of co-operation, but they are not fair examples. They are not strictly co-operative concerns, but are really only joint-stock companies with a free market for their shares. Mr. Balfour counselled moderation in the undertaking of production by co-operators. He pointed out as above and otherwise that co-operation involved several weak points, and his advice was to restrict co-operative efforts, for a time at least, to such industries as involved the fewest of such weak points. Curiously enough, though the statistics of English and Scotch co-operative production were not favourable, in Ireland they were better. Though the Irish movement was only 10 years old, there were already 400 co-operative societies in Ireland—banks, agricultural societies, but chiefly, we believe, dairies. Those who know anything of the conditions which obtain on an Irish farm, and the absolute heedlessness of dirt, cannot but appreciate well the reasons for the defeat of the Irish by the Danes. Equally will they appreciate the great advantage of the clean built dairy away from farm buildings, to which each small farmer may bring his few gallons of milk, and have it converted, in a cleanly manner, to a marketable article. But after all, the co-operative dairy in Ireland was undertaken by men who did not seek employment in the dairies; they are themselves the producers of the raw material, which we presume they are credited with, according to its value, by lactometer or other recognised system. As Secretary for Ireland, Mr. Balfour no doubt has had opportunities for gaining an insight into the Irish movement, which he so well referred to, and with which he rounded off his speech. But while we fully recognise the great benefits to be obtained from co-operative dairies in Ireland, we see, as we fully believe Mr. Balfour sees, that this is no real argument for a general co-operative production. It is really an argument for production on a larger scale than is possible to the owner of only two or three cows; it is an argument for cleanliness, for probably the majority of small Irish farmers have not a sufficient supply of clean water to hand, whereas the dairies are able to afford the expense of a bored artesian well, and of steam for cleaning utensils. They can afford De Laval separators; but a co-operative engineering shop cannot afford anything that is not within the reach of a wealthy private firm or of a joint-stock company. None of the reasons usually advanced in favour of co-operation operate to make Irish dairies a success. The Irish dairies employ paid servants, who are not co-operators in the sense of being proprietors, and any private capitalist could establish a dairy with equal success, and many would do so but for fear that some fine day their raw material would be withheld from them without reason. They would awake to find they had been boycotted for some fancied wrong they had done. The small farmers are not likely to boycott their own dairy, which must succeed if only it be kept clean. What they need is a sense of the presence of dirt. This sense seems to be strangely absent. Toleration of the stranger is also required; a stranger may do his best to establish an industry, and he will meet with every possible form of obstruction. There is no incentive to lay out capital in such a country, and the result is the general ruin which is so apparent in the South and West. The success of the co-operative movement in Ireland does prove what is possible in the country, but it tells us only too plainly that all this late success could have been achieved years ago but for the uncertainty under which capital is invested in Ireland. Exactly the same process has been going on in England for some years under the auspices of the Amalgamated Society of Engineers, and if the check of 1897 be not permanent, it will reduce English industry to as low an ebb as that of South and Western Ireland.

THE GLASGOW TRAMWAY ENGINE CONTRACT.

The following important letter on the above subject, to which we make reference at length in another column, appears in the *Manchester Courier*:—

"Soho Iron Works, Bolton, *August 16th*, 1899.

"Sir,—The *Manchester Courier* of to-day contains a paragraph to the effect that the Glasgow Tramways Committee had yesterday accepted the tender of an American firm for the engines required for the new power station at a price rather more than twice that tendered by a Glasgow firm of engine builders. We also submitted a tender for the engines, our offer being some £20,000 below the tender which is now stated to have been accepted, and we think we, and other British engine builders, may fairly complain of having been specially invited to incur the serious expense involved in the preparation of designs and estimates if it was a foregone conclusion that only the engines of one, and that an American, firm would satisfy the requirements of the committee and their engineer. Our experience in connection with this contract will probably be of interest to engine builders.

"On perusing the specification we found it to contain a number of anomalies which required explanation before we could prepare any reliable tender, of which the following are examples:—(1) Crosshead pins as large as, or larger than, the crank pins. (2) A piston rod 10 inches in diameter for both a single 88-inch low pressure cylinder and for each of the two 60-inch cylinders named as alternatives, the high pressure rod in each case being 9 inches in diameter. (3) A single 88-inch cylinder named as the equivalent of the two 60-inch ones, 85-inch being the actual equivalent, though a still smaller one might reasonably be used, owing to the loss by friction being less with the two-cylinder design. (4) A coupling apparently desired between the 100-ton fly-wheel and one of the bearings supporting it. (5) Crank discs, apparently of cast-iron, in place of the steel or wrought-iron cranks universally used in English marine practice for similar shafts. (6) A 32-inch crankshaft for transmitting 4,000 to 5,000 I.H.P. at 75 revolutions, against the 18-inch shaft which would about accord with English marine practice, the strengths of the two being as 5½ to 1. (Owing to the fly-wheel being interposed between the engines and the generator, the stresses on the crankshaft would be much less severe even under the conditions of electric traction than in the case of marine engines, liable to race in heavy weather.) (7) The suggested number of bearings and sections of shafting would not fit any usual arrangement of shafting that we could think of. (8) An oil pump specified to be of 'equal capacity' to a 2-gallon lubricator.

"With these anomalies before us, and being anxious to go fully and seriously into the matter, we sought and obtained an interview with the committee's engineer, visiting London for the purpose. No explanation was forthcoming, but it was pointed out that the dimensions, &c., were only 'suggested,' and we were requested to tender in accordance with our practice. This we did, submitting full designs and particulars, and adding—'We have given a great deal of consideration to the design and cost of the engines for which we have now the pleasure to quote you, being very desirous of obtaining the

Digitized by Google

order for them; but we fully recognised that even the somewhat voluminous papers we are now sending to you do not by any means cover the whole ground, and we wish to express our readiness and desire to have the opportunity of discussing the various points with your engineer, should our tenders be acceptable to your committee; and, in such case, we have no doubt that we could come to a full and satisfactory understanding as to both the general design and the details of the engines which are required.'

"We next received an official communication to the effect that whilst the total weight of our engines seemed satisfactory, our dimensions differed so much from those specified that it was desired to know whether we were prepared to accept the latter. We replied that the specification not being quite clear we could not give an unqualified answer, but asked an interview in order to arrive at an understanding. This being declined, we submitted further designs, explaining the nature of our difficulties, and offering to go further into the matter on being informed as to the wishes of the committee, also renewing our offer of a personal interview.

"On the evening of August 14th we received an official telegram from the town clerk, inviting our attendance at a special meeting of the Tramway Committee to be held the next day 'in order to explain any points in connection with our offer.' We gladly made a special night journey to Glasgow for the purpose, but, after waiting outside the committee room for some time, were told that the committee had declined to see any tenderers, and decided to recommend the acceptance of an American tender.

"So much is heard at the present day as to orders going to America which ought to be executed in this country that we think the above account of our experiences and the difficulties thrown in our way cannot fail to be interesting to other contractors as well as to the Glasgow ratepayers.

"We desire specially to call attention to the fact that in such a highly technical matter as that in question we were denied the opportunity of discussing or explaining a single technical point in connection with our tender or obtaining an explanation of difficulties involved in the specification. Whilst personally we received every courtesy from the officials with whom we came in contact, we must maintain that we as a firm were treated in an unbusinesslike and inconsiderate way, if only on the ground that we were invited to tender for, though apparently deemed incapable of carrying out, so important a contract. On this point we venture to quote an extract from a letter received from one of the most important South African houses, to whom we have supplied a number of large engines for gold mining purposes, and from whom, in view of this business, we asked a comparison of our own and American engines. After explaining that these engines are employed under very arduous conditions, they add:—'Coming to the point of the actual quality of material and workmanship, we may say that your engines are distinctly superior to the American engines that we have seen, and which cover those made by the leading makers in the States. For instance, where you employ cast and wrought-steel the Americans generally use cast-iron. We are bound to say that these American engines work well, but we are convinced that, in point of durability and the important question of repairs, they do not compare favourably with your engines, and in cases where stoppages would involve serious consequences, we should certainly prefer to put down one of your engines rather than any American engine we have seen, and we have had very considerable experience. We may inform you that the leading American engineers have inspected the engines supplied by you, and have expressed their admiration of same. As far as we are concerned, we can only express our entire satisfaction with the engines you have supplied us.'—We are, Sir, yours, &c.,

"For Hick, Hargreaves & Co., Limited,

"Andrew Reason, Secretary."

The E. P. Allis Company, of 39, Victoria Street, S.W., sends us the following copy of a letter adressed by it to the *Manchester Courier*:—

"August 22nd, 1899.

"To the Editor of the *Manchester Courier*.

"Sir,—We are builders of Corliss steam engines, and have for many years made a speciality of electric traction plant. In its interest we tendered to the specification issued by the Corporation of Glasgow for its tramway station engines. The Tramway Committee favourably considered our tender. The Council refused to pass the findings of the committee, and we are informed that a new competition is to be opened.

"We are, of course, unable to more than guess at the reason for such action. There was nothing in the specification at which anyone familiar with the demonstrated requirements of large electric traction plants could cavil. Naturally it did not follow British practice, for the exceedingly simple reason that there is no such application of electric power in the United Kingdom. It was simply a model plant, designed in the light of great modern experience, with a view to rendering the best economies to the municipalities to which it was offered.

"It was presumed by us that the committee to which the interests of the Corporation were committed knew what it was about, both in the selection of its engineers and in approving the specifications prepared by them. We did not think it necessary to visit Glasgow to make personal appeals to the members of the Local Government, or to resort to the columns of the public press for support while the matter was under consideration. We tendered absolutely to both alternatives of the specification, and we certainly believed that an American house, invited to an open competition by a great Corporation, might reasonably expect to be squarely and fairly dealt with.

"We repeat that the specification, as submitted to competition, embodied nothing but the results of the best accepted practice of similar installations. The only 'anomalies' discovered by our competitors arose out of their ignorance of the conditions that exist, and their inexperience of those methods of construction which have been found to best meet those conditions. Furthermore, every advantage lay with the British builder. The engines are special, therefore all who tendered were on the same footing as regarded design, plans, patterns, &c. The Allis Company were handicapped by a 1,000 miles of inland and 3,000 miles of ocean freights. Its engineers made that long and costly voyage to prepare their tender, not the 'special night journey to Glasgow' (from Bolton!), which one competitor so pathetically deplores in an open letter to the press.

"We did not take it upon ourselves to instruct the Glasgow Corporation as to how a cheaper and less substantial and effective machine might be secured for its use. It could afford to purchase the best thing that money could buy, and we were luckily in the position of having at our disposal the men and tools and facilities which could turn out the best—and the best was specified to us.

"Our competitors have devoted much time and space to a demonstration of the various methods whereby they proposed to apply data derived from marine and other practice to the needs of the Glasgow tramway plant. That discussion may be of absorbing professional interest, may possess charms to the student of acrostics or anagrams, but we regret to say that we are unable to discover its practical value or its relevance to the question under discussion. The modern tramway power plant has been developed from 15 years' experience with tramway plant, and from some 50 millions sterling which has been expended on such plants, and the day when workers on traction problems drew inferential designs from marine, or shop, or rolling mill practice is now ancient history.

"The long and short of it is, that instead of meeting the question openly and fairly, our competitors have endeavoured to bring such pressure upon the Glasgow Corporation as may induce it to accept an article of their manufacture, even if it be inefficient, unreliable, or antiquated.

"If that end be attained, we fail to see that any result is gained by the Corporation from the long and careful study of electric traction which has been made by the Tramway Committee and its engineers, involving expensive journeys to visit the representative modern systems of the United States and Europe.

"We feel ourselves aggrieved, and, we think, justly.

"Our tenders, prices, and specifications have been openly discussed and every advantage now given to our competitors. We can see little of that 'fair play' so hypocritically invoked in a 'competition' which is reopened whenever a home competitor fails to secure the contract, or in re-casting specifications until the favoured bidder finds them adapted to his limitations. To invite American houses to offer under such conditions is not only absurd but radically wrong. If the game is to be played under such rules it would be vastly fairer to exclude the American manufacturer altogether, and not invite him to expend his time and money needlessly.

"It is undoubted that a municipality has every right to decide to support home industry to the exclusion of all outsiders, but it may very properly be questioned whether the proper time to arrive at that conclusion is after outsiders, at the request of the municipality, have placed at its disposal all their data under the mistaken supposition that serious business was offered.

"Referring especially to Messrs. Hick, Hargreaves & Co.'s criticisms which were set out at length in your columns a few days ago, we beg to say that the various dimensions of pins, piston rods, and cylinders on which they animadvert, coincide very closely with the accepted best American practice in such engines, and we would repeat that there is no other source from which practical results can be drawn. It is useless to discuss why this be so, especially as we do not presume that you would care to have the whole theory and practice of steam engineering as applied to traction and wherein it differs from marine work, set forth at length in your columns.

"In our copy of the specification no mention was made of a coupling in the two-crank engine. One was specified in the three-crank engine, but it was between the outer bearing and the generator, not as stated by Messrs. Hick, Hargreaves & Co. All crank discs supplied by the Allis Company for such engines are steel, and the specification called for cast-steel throughout. They were not 'apparently cast-iron,' as Messrs. Hick, Hargreaves & Co. put it.

"Their statement as to proper strength of shaft is also incorrect. The shaft would have to stand a torsional strain equivalent to 10,000 H P. or more (instead of the 4,000 or 5,000 H P. they refer to.) It would also have to carry some 100 tons of fly-wheel. Messrs. Hick, Hargreaves & Co. evidently disregard the trifling fact that the necessary area of bearing and lubricating surface has something to do with shaft dimensions.

"That the suggested number of bearings would not fit any 'usual arrangement of shafting,' of which Messrs. Hick, Hargreaves & Co. have cognisance, is eminently possible. It is, however, one very usual in traction practice. Possibly, they may have overlooked that bearing between the 100-ton fly-wheel and the coupling, already referred to.

"We are naturally interested in the somewhat lengthy but exciting account of Messrs. Hick, Hargreaves & Co.'s various peregrinations and failures to meet the Tramway Committee and its engineers before their tender was considered. May we venture to suggest that 'the officials with whom they came in contact,' evidently went to a considerable length of politeness when an engine maker, who was confessedly chasing them down to get them to take something they did not consider met their needs, 'received every courtesy' at their hands. Our own experience leads us to believe that scant courtesy would usually be meted out under such conditions.

"We have no objection to the '6-inch ad. reading columns' which Messrs. Hick, Hargreaves & Co. have ingeniously worked into their letter. That is good business, and we are not at all above doing the same ourselves when opportunity offers. We have a book of those ourselves which we are prepared to distribute broadcast. It would

Digitized by Google

have been better though if Messrs. Hick, Hargreaves & Co. had taken their comparison between 'American' and English machines nearer home than Africa. The Allis Company now show a considerable number of engines of their make running in England, which are already available for purposes of comparison. By the end of this year, when the large plants we have now in hand for the Central London Railway, the Dublin, Bristol, Isle of Thanet, Sheffield, Cork, and London United Tramways, the London (Bankside and City Road electric lighting stations), and the Ellesmere Port Smelting Works are fairly finished, we shall be delighted to afford every opportunity for further comparison of design, material, and performance.

"We must, however, say that we note that Messrs. Hick, Hargreaves & Co.'s African friend can only compare their engines with the somewhat indefinitely stated 'American' type so far as 'material and workmanship' goes. Possibly the reason the Glasgow Committee approved of the Allis proposition was on the score of that economy in working and strength which the African gentleman does not touch on.

"At all events, we learn from Glasgow that our proposal surpassed all others in the guaranteed steam consumption, the weight and strength of the engines offered, and the rapidity with which delivery could be made. All good points, and well worth serious consideration.

"With our very sincere apologies for intruding so greatly on your valuable space, and like Messrs. Hick, Hargreaves & Co., 'appealing to your sense of fair play to insert this letter in your paper.'

"We are, Sir,

"Your very obedient servants,

"The Edward P. Allis Co."

The following letter appears in the *Glasgow Herald*:—

"Caledonian Hotel, Fort William,

"*August* 18*th*, 1899.

"Sir,—On a holiday in Scotland I have been following with interest the question of the Glasgow electrical tramways and the recommendations of their American engineer. Your report to-day is especially interesting reading, and if you will permit, I should like to make one or two remarks. Mr. Paton must be in ignorance as to what other countries in Europe have achieved in the matter of electric traction, or he would not state that 'almost the whole traction engines working for tramway purposes in the world had been made by American engineers.' Allow me to remark that on the Continent he would not find many American engines, but absolutely as good, efficient and economical machines by makers such as the Goerlitz Company (Germany), Franco Tosi (Italy), and Vanden Kerchove (Ghent). The Corporation of Glasgow, if real Free Traders, could therefore quite as well have asked any of the above Continental firms to tender, and I know they would have got quite as good an engine, delivered and erected within 12 months. But really there was no need to go outside the United Kingdom. Engineers such as Messrs. Hick, Hargreaves & Co., of Bolton, or Messrs. Browett & Lindley, of Patricroft, Manchester, could easily supply what was required without fear of constructing fly-wheels that burst, as they do in the U.S.A. But one cannot blame Mr. Parshall. As an American, with purely American experience, he has a bias in favour of engines he knows; and that is natural. Glasgow appointed him, and must take the consequences. To many of us engineers, however, it appears strange that the Scottish city did not consult one of the highest British authorities—namely, Prof. A. B. W. Kennedy, F.R.S., himself a Scotsman—than whom none probably has greater experience in matters relating to steam engines, as well as in matters electrical. I have the honour to be connected with the English branch of the largest German firm of electrical engineers, the 'Allgemeine Elektricitäts-Gesellschaft'; and, although we could have offered Glasgow quite as good a plant as any American firm, we did not tender, as it appeared a foregone conclusion that the orders would go to American firms, such as the Allis Company, the Thomson-Houston and Westinghouse Companies. Charles Weiss."

SOME COMMENTS ON THE HARTFORD LONG-DISTANCE TRANSMISSION PLANT.

By E. K. Scott.

The introduction of the rotary converter into practical electrical engineering has brought forward a number of special features, and one of the first papers to give particulars of these in any detail is that recently presented to the National Electric Light Association at New York by Prof. W. L. Robb. The author of the paper describes the conditions under which the two-phase transmission plant at Hartford is operated; the difficulties met with; the way they have been overcome, and the advantages which have been found in the combination of rotary transformers and accumulators for electric lighting.

As the system described is more or less on the lines which are about to be introduced at Manchester by the Metropolitan Electric Supply Company, the Blackheath and Greenwich Electric Supply Company, &c., the following summary of the main points in the paper, and the discussion, may be of interest:—

GENERATING PLANT.

Power is taken from the Farmington river, about 11 miles from the city of Hartford, and the water-power at present developed is capable of delivering 1,200 H.P., the energy being transmitted by two-phase current at 10,000 volts and 60 cycles per second.

Steam Plant.—There is an auxiliary steam plant in Hartford itself, consisting of two compound condensing Corliss engines having a combined capacity of 1,600 H.P. These engines supply the power to operate one 600-KW. alternator and one 400-KW. rotary transformer, the latter so arranged that it can be connected with engines and operated as a direct or as an alternating current generator. The type is known in America as a "driven rotary." This rotary machine is worked as a generator whenever, owing to low water or repairs on the transmission line, the supply of alternating current is insufficient for the alternating current load and all the rotary transformers.

Parallel Running.—The three generating units—two operated by water and one by steam—have been continuously run in parallel during the last three years, and no difficulty whatsoever has been found, although the two sets of plant are of course 11 miles apart.

ROTARY TRANSFORMERS.

Three rotary transformers supply direct current to the three-wire direct-current system. One, mentioned above, has a capacity of 400 KW., and is located at the steam plant. Two others have a capacity of 250 KW. each, and are located in a battery sub-station, which is situated in the heart of the business section of the city, and about three-quarters of a mile from the steam plant.

Speeding Up.—Two of the rotaries are started and brought into synchronism by induction motors built on their shafts; the third is speeded up as a direct current motor, the current necessary for this being supplied from the accumulators.

Alteration of Voltage.—The machines are so designed that, by cutting in or out turns of the primary of the static transformers the voltage on the continuous current side may be varied between 230 and 360 volts. This wide range of voltage is necessitated by the fact that the rotaries are at times run directly on the line, and at other times used in charging the battery. The rotary transformers are two-wire, and simply supply the current to the outside wires of the three-wire system, the neutral wire being connected with the middle point of the secondaries of the two static transformers. This point being always midway as regards electric pressure between the two terminals of the rotary transformer.

Treatment of Carbon Brushes.—When first started there was considerable sparking at the commutator. It was found that very soft carbon brushes gave the best results, but without special treatment the sparking, although diminished, was still excessive. The following method of treating the brushes was found effective. The carbon brushes are first raised to a red heat, and then plunged in ordinary lubricating oil and allowed to cool.

Pumping of the Rotaries.—At the outset considerable difficulty was met with in preventing pumping when the engines were supplying power to the system, the pumping being traced to the variation in the angular speed of the engines. It was found that the tendency could be checked by varying the field excitation of the rotary transformers, or by temporarily throwing a portion of the load on to the storage battery. The 400 KW. rotary transformer, when tested by itself, proved to be free from any tendency to pump, either when operated from the steam plant, or from the water-power. When, however, it was thrown on to the line with the two other rotaries, they immediately began pumping, and it was found impossible to run the three machines together. The pumping in a rotary system seems to be cumulative; it is very easy to stop it if the proper remedy is applied as soon as the tendency is noticed, but if allowed to go on, it quickly gets beyond control. The impossibility of running the three rotaries together necessitated some cure, and this was found in attaching copper strips to the pole-pieces of the machine.

SYSTEMS OF DISTRIBUTION.

Two systems of distribution are used:—(1.) In the central portion of the city distribution is on the three-wire, 220-volt, direct current system. The feeders are lead-covered cables, drawn in cement lined ducts, and the distribution partly by Edison tubes and partly by lead-covered cables drawn in ducts. (2.) Outside the central portion of the city the feeders are supplied with two-phase alternating current at 2,400 volts pressure, and the distribution is on the three-wire, 220-volt, system, supplied from 10 or 20 KW. transformers. This service is partly underground and partly overhead.

Continuous Current Motors.—The direct-current system of distribution was adopted for the central portion of the city, as being the only one on which all kinds of service could be given from the same wires, especially if those wires were placed underground. In this section of the city a large number of motors are being frequently stopped and started, and it was considered that induction motors operated under these conditions would seriously interfere with the lighting service.

Induction Motors.—In certain sections of the city where the motors are in continuous use—for example, when they are used for running machinery in factories, and consequently are only started twice a day, there is no difficulty in operating induction motors and lights from the same system of mains.

Digitized by Google

Arc Lighting.—The arc lamps are all of the enclosed type, some being operated by direct current from the three-wire network, and the others worked in series from constant current alternating transformers. About 400 watts are supplied to each alternating current lamp, the transformers being operated from sub-stations. The inspector of the district turns the lights on and off, and visits the transformer house once only during the night. The transformers were practically automatic. They were made of two stationary coils and two movable coils, balanced on knife edges. The only motion is at the knife edge when the transformer is started and stopped.

ACCUMULATORS.

The storage battery has a capacity of 2,500 H.P.-hours at a five-hour rate of discharge. All three rotaries and the battery supply currents to the same three-wire direct-current system, the battery being at all times kept on the line for the purpose of regulation, and to meet any emergency call for extra power.

Maintenance Guarantee.—The battery was bought under a five-year guarantee, which has since been renewed for five additional years. The renewals have not been in excess of what was expected, and no investment of the company has been considered more satisfactory than the battery. Whenever any plate or number of plates have lost one-third of the original capacity, they are replaced by new ones; in this way the battery capacity is never less than 90 per cent. of its original amount.

Advantage of Combining Rotaries and Cells.—The advantages of the rotary transformer and battery system to the Hartford Company have been very great, for they have been able to use a great quantity of water-power that would otherwise have gone to waste. This has been utilised at the peak of the load at the time when power is most valuable. The total output of the water-power during the past year was over 90 per cent. of the possible output.

When operating by steam the engines have been run at an economical load, the advantages of the storage battery being nearly, if not quite, as great in connection with the operation of the steam plant as of the water plant. The regulation of the system is much better with the battery than it could possibly be without it, and the service is much more reliable. The interlocking of the battery with the alternating current by means of the rotary transformers makes the battery act as a regulator on the alternating current system as well as on the direct. During the day time on Sundays the entire load, both direct and alternating, can be carried by the storage battery. The battery has frequently been allowed to feed the alternating system through the rotaries. The transformer and battery station is operated by three men—the superintendent (an expert in the care of batteries) and two switchboard attendants.

It will be seen from the above that Prof. Robb is most enthusiastic as to the value of a storage battery in connection with electric lighting. It is a curious thing that the American engineers should be only just recognising that, for regulation, and to carry over the peak of the load, there is nothing to equal the use of accumulators. The guarantee of 90 per cent. for five years is a particularly good one, and shows that the American accumulator manufacturers are more enterprising than the British firms.

The method of varying the voltage on the continuous current side of the rotary by cutting in and out coils of the static alternating current transformers is interesting; if for nothing else, that it shows that the subsidiary booster is not an absolute necessity for charging cells in large stations. The writer thinks, all the same, that the booster has come to stay.

If the method of quenching carbon in lubricating oil does all that is claimed in the way of stopping vicious sparking, it ranks as an important discovery. In any case it is easily tried, and the writer trusts some engineers-in-charge will write saying whether they find the method beneficial on English machines.

The question of the pumping of rotary converters brings forward an important question for engineers on this side, as there are very few places in England where the even turning of a water-power plant is obtainable. It is true that we have the three-crank high speed engine, and if pumping does occur, the method employed at Hartford can be used. It is just a question, however, whether it would not be better to fight shy of the rotary converter altogether, and employ instead a self-starting induction motor, coupled to one or two ordinary multipolar machines, as has been advised by the engineers connected with the Blackheath and Greenwich Company. Unless some method of greatly increasing the speed is adopted, as, for example, the writer's suggestion for running transformers vertically, the number of poles of the rotary converter must always be very much out of proportion to the output. If a draughtsman were to set to work deliberately to design a very bad continuous current multipolar machine, he would make it with three or four times as many poles as it need have, and place a set of brushes at each pole. Well, this is exactly what he has to do in getting out a rotary converter, because the number of poles is governed entirely by the speed and the frequency, and the armature must of necessity be parallel wound to get the proper connections to the slip rings. For power work only, there is something to be said for the rotary, because then the frequency may be low, say, 25 or even less, and the number of poles so kept within bounds. For various reasons, however, 50 cycles per second is more likely to be used in this country.

The neutralising of the armature reactions by having continuous current and multiphase alternating currents circling round one armature core saves something in material (just as a single core continuous current transformer is cheaper than if two machines are simply bolted together), but it must be remembered that the rotary converter has to be brought up to synchronism either by a separate self-starting motor or else with current from the continuous current side. This latter method presupposes that there is continuous current to draw upon, which, of course, may not always be the case.

Assuming that 250 KW. have to be dealt with, and that the live current is two-phase alternating current at, say, 3,500 volts and 50 periods per second; also that the lighting is from a three-wire continuous current network, with 440 volts across the outers, then a comparison of the two methods stands somewhat as follows:—

Rotary converter (running synchronously).	Self-starting induction motor, coupled to two ordinary multipolar dynamos.
Two static alternating current transformers, one in each phase.	None required, the full voltage being taken straight to the induction motor.
Four heavy low tension cables from the transformers to the slip rings of rotary.	None required.
Rotary running at, say, 500 revolutions, will have 12 poles. As armature must be parallel wound, there will be 12 sets of brushes to care for.	Dynamos built in the ordinary way on the most efficient lines. With series-wound armature there would be only two sets of brushes per machine.
To get the machine into synchronism, a small self-starting motor is required; or else switch-gear, to enable it to be speeded by working the continuous side temporarily as a motor.	The combination is always self-starting by means of auto-transformer. There is thus no need for special switch-gear on the continuous current side.
Voltage 460 volts across outers, with middle wire brought back to middle point of secondaries of the two static transformers. No regulation possible on each side of middle wire.	The voltage on each commutator, say, 230, the middle wire connected up in the usual way. Wide variation of voltage on each side by merely regulating field current.
For charging cells the voltage is varied by cutting in and out turns of the primary windings of the static transformers requiring special switch gear.	For charging cells the voltage may be temporarily raised by strengthening the fields of the dynamos, or if preferred a booster can be used.

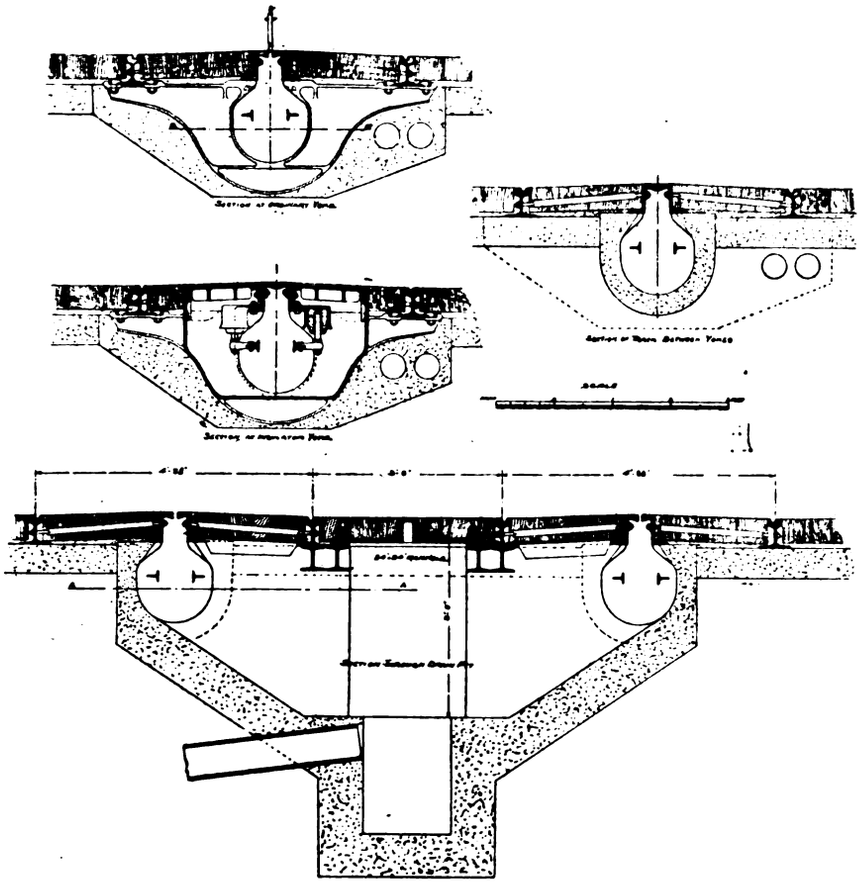
The rotary converter takes up less floor space, but there is very little, if any, difference in price. Something may be saved in the second case by using a two-commutator dynamo instead of two separate machines, or a single commutator machine feeding direct on the outers may, of course, be employed.

THE LONDON UNITED ELECTRIC TRAMS.

THE London United Tramways Company has favoured us with drawings relating to its electrical lines within the County of London. The details of the scheme and the equipment were given in an article in our issue of July 7th. The line from Acton to Shepherd's Bush,

Digitized by Google

and from Shepherd's Bush to Young's Corner, at the western boundary of Hammersmith, will be electrically equipped on the overhead trolley system, and will connect with the Kew and Hounslow line at Young's Corner, so that the overhead trolley system will extend from Acton by way of Shepherd's Bush to Hounslow.



London United Conduit.

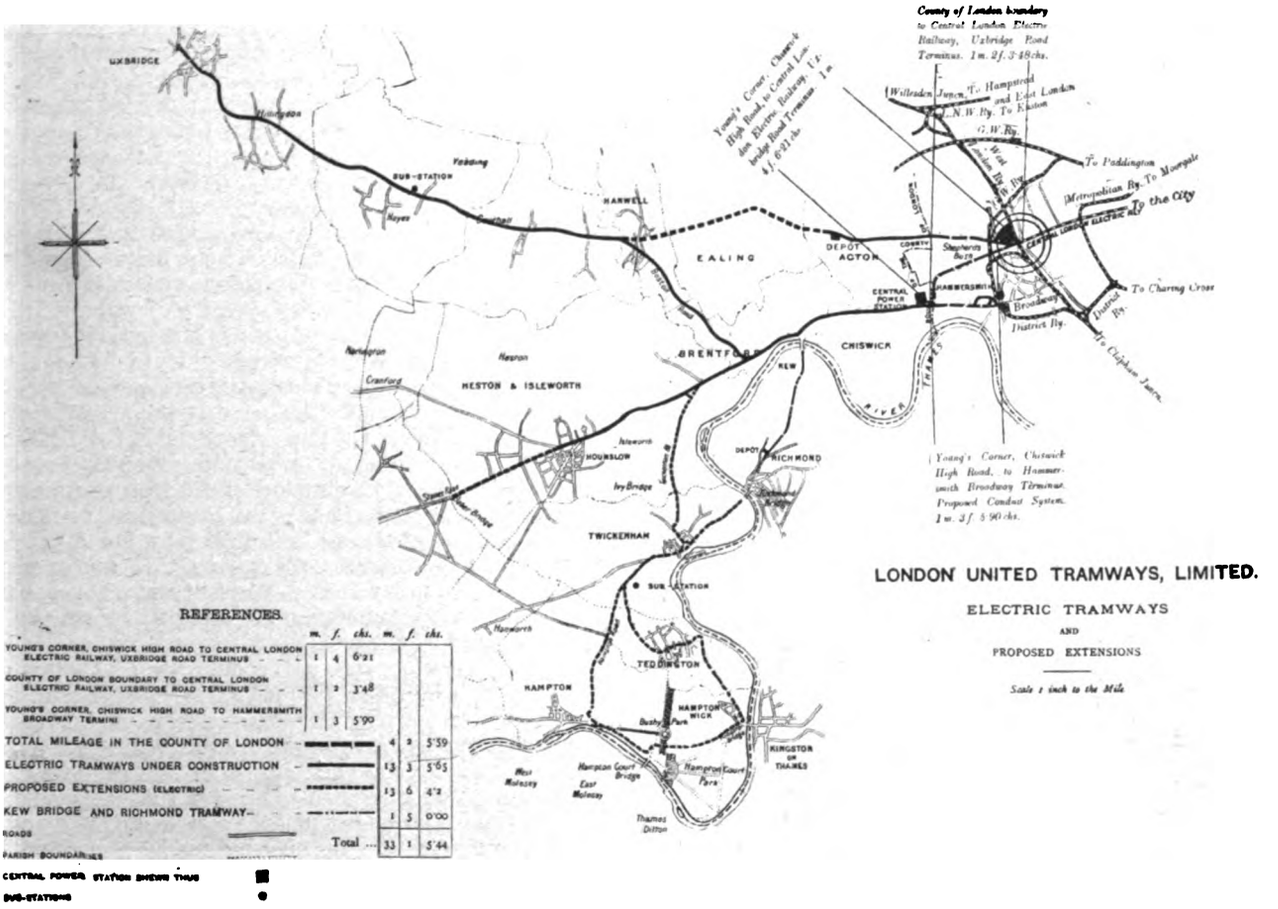
The proposed conduit system as shown on the drawings, which we reproduce, is for that portion of the company's lines between Young's Corner and Hammersmith Broadway, as required by the London County Council, a distance of about 1 mile. The roadway will be supported on yokes spaced 5 feet apart, bedded on Portland cement concrete; the depth of excavation required will be 3 feet from the upper surface of roadway, and there will be a slot ¾ inch wide in the centre of each line of track. Handholes with covers will be placed every 15 feet, and manholes connected with the sewers for draining the conduit will be provided at intervals of 150 feet.

In view of the importance of this system of the London United Tramways, and the great interest which is being taken therein, we reproduce a map showing the districts to be served by the several sections, with the extensions proposed up to June, 1899.

Mr. J. Clifton Robinson is the engineer to the company, Mr. H. F. Parshall being the consulting engineer.

THE NATIONAL PHYSICAL LABORATORY.

The definite initiation of this important step in the progress of scientific engineering in England has now taken place. We reviewed the proposal in its general aspect last year, when the stage had been reached of a consensus among the different authorities concerned as to the practical mode of carrying it out. At that time the committee appointed for the purpose had devised a scheme the Treasury was likely to accept, and now Parliament has voted



Digitized by Google

the money, and the governing body of the new institution has been appointed for the purpose. The *Times* of August 15th gave some details of the arrangements that have been made.

The laboratory is to be an extension of the Kew Observatory in the Old Deer Park at Richmond, and for the purpose of the extension the Treasury is to find £12,000.

The annual income of the new institution will consist of £458, the endowment of the old laboratory from the Gassiot trust, of £4,000 from the Treasury, and of the fees received for the verification of instruments. These last have amounted annually to £2,700, and should produce a considerably larger income in the future. Thus the institution begins with an income of upwards of £7,000 a year.

The ultimate control is in the hands of the Royal Society, the immediate control in the hands of an executive committee and a general board, any alteration in the constitution of the two latter bodies requiring the consent of the Treasury. This is, of course, the usual arrangement of public institutions in England, and is immediately modelled upon the constitution of the Greenwich Observatory. An executive authority, a visiting authority, and an authority capable of altering statutes seem to combine in a convenient way the rigidity of a continuous rule and policy with the flexibility necessary for changing circumstances. Its success usually requires that the executive should be fairly susceptible of external influence, and the constitution in this case, so far as can be judged from the information before us, promises well. The executive committee will ultimately consist of 17 members, of whom five are official; viz., the chairman of the committee, the president, treasurer, and one secretary of the Royal Society, and the permanent secretary of the Board of Trade. Of the other 12, six are appointed, one by each of the principal technical societies; viz., the Civil, Mechanical, and Electrical Engineers, the Naval Architects, and the Society of Chemical Industry. How the other six are to be appointed is not mentioned. In the first instance, the existing Kew Observatory committee will be represented by six members, but on the expiry of their term of office their places will not be filled up.

This executive committee will report annually to the general board, a relatively large body, and will submit to them its scheme of work for the ensuing year. Six members of the general board will be nominated by the six technical societies beyond the six appointed to the executive council, and it is evidently anticipated that this strong representation of the commercial interests will keep the body fairly in touch with the practical requirements of the country.

The council of the Royal Society has appointed Mr. R. J. Glazebrook, the principal of University College, Liverpool, to be director of the National Physical Laboratory, and the following are the members of the executive committee:—

Lord Lister, P.R.S., Lord Raleigh (chairman), Mr. A. B. Kempe, Treas. R.S., Prof. A. W. Rücker, Sec. R.S., and Sir Courtenay Boyle (*ex officio*), Capt. W. de W. Abney, Sir N. Barnaby, Mr. G. Beilby, Sir E. H. Carbutt, Capt. E. W. Creak, R.N., Prof. R. B. Clifton, Prof. G. C. Foster, Mr. F. Galton, Prof. O. J. Lodge, Sir A. Noble, Prof. J. Perry, Sir W. Roberts-Austen, Prof. A. Schuster, Mr. A. Siemens, Gen. Sir R. Strachey, Prof. J. J. Thomson, Dr. T. E. Thorpe, and Sir J. Wolfe Barry.

In addition to the above, the following are also members of the general board:—Sir M. Foster, Sec. R.S. (*ex officio*), Sir F. A. Abel, Prof. W. G. Adams, Prof. W. E. Ayrton, Mr. H. Bell, Mr. A. Buchan, Mr. R. E. Crompton, Prof. G. F. Fitzgerald, Prof. J. Joly, Lord Kelvin, Mr. J. T. Milton, Sir W. H. Preece, Mr. W. F. Reid, the Earl of Rosse, Dr. R. H. Scott, Mr. W. N. Shaw, Mr. C. E. Stromeyer, Admiral Sir W. Wharton, and Sir W. H. White.

The following have also been requested to serve on one or other of the sub-committees above referred to:—Messrs. E. D. Archibald, C. V. Boys, Prof. H. L. Callendar, Messrs. Forbes, Carpenter, W. H. M. Christie, J. H. Dallmeyer, Prof. J. A. Ewing, Mr. S. Z. de Ferranti, Prof. J. A. Fleming, Messrs. R. E. Froude, E. H. Griffiths, J. Mansergh, T. Matthews, W. H. Maw, Dr. L. Mond, Hon. C. A. Parsons, Prof. A. W. Reinold, Captain H. R. Sankey, Messrs. J. Swinburne, G. J. Symons, H. A. Taylor, Prof. S. P. Thompson, Messrs. J. I. Thornycroft, C. H. Wordingham, and A. F. Yarrow.

Mr. Glazebrook is to enter office at the beginning of the new year, and a definite scheme of work is to be arranged during the autumn. The announcement of this will be of great interest, as it seems certain that some of the electrical questions must be among those to be dealt with first. Of all the appointments Mr. Glazebrook's is, of course, by far the most important, and we hope he will obtain a reputation for energetic administration and initiative not inferior to that which he now enjoys for scholarly exactness. He has hitherto come into contact with electrical engineers principally through his official comparisons of standards of resistance at the Cavendish laboratory at Cambridge.

SOME CONSIDERATIONS AFFECTING GAS ENGINES.

In connection with our recent remarks on the Westinghouse gas engine, it may not be amiss to go further into the subject with a view to establishing some fixed idea as to the working of gas engines in the production of electricity. When the gas engine was first introduced it was wasteful. It is wasteful still, but it was more especially so in its early days. Almost the whole of the endeavours to improve gas engines are along the line of economy. Something of this is due to the fact that gas engines were more essentially the small manufacturers' motive power, and the only available source of gas was the town main. Economy of gas was more valuable than regular turning. It mattered very little that a chaff-cutter or a small printing press had a very variable speed, and the gas engine, as developed in Europe, has almost invariably been constructed on the hit-and-miss principle of governing in order that the superior economy of this principle of action might be secured. Illuminating gas has been so costly in America, that the progress of the gas engine has been very slow up to recent dates; but now that it has been proved capable of being constructed in large sizes, the gas engine has appeared to Americans as eminently suitable for use with their cheap natural gas and with producer gas, and we cannot but think that in abandoning the more economical principle of hit-and-miss governing in favour of more wasteful moderated charges, American constructors have followed correct lines. Unless a gas engine is worked up to its maximum load, it cannot be other than irregular in action under the hit-and-miss principle, and so far irregular as to unfit it, in the opinion of some, for direct connection to lighting dynamos.

The Westinghouse engine, when using London gas at full load, will generate 40 KW.-hours on a consumption of 1,000 cubic feet of gas. At 2s. 6d. per 1,000 feet, this is equal to ¾d. per KW.-hour, or 1½d. including attendance, maintenance and depreciation, which compares favourably with the prevailing price of 4d. to 6d. per unit.

But 2s. 6d. is a very high price to pay for gas, and far away in excess of the cost of an equivalent capacity of energy in the form of producer gas, and there can be no doubt that a H.P.-hour can be produced by means of gas engines with not more than 1 lb. of fuel. Under these circumstances, it may well be doubted whether it is worth while to neglect the gas engine simply because it works to best advantage when governing on the system of moderated charges. Obviously, under any system of governing, the gas engine will be most economical when it is working up to its maximum effort. When working near to its maximum capacity, it cannot matter much whether one or the other system of governing is practised, for it is only at reduced load that the difference of the two systems is felt. There is no difference in the engines to account for any difference of economy—it is simply a question of the gas mixture. In the Westinghouse engine, the less economical system has been adopted, a system so far adopted by few others, and we believe by no maker of large engines. If the purchaser of a gas engine can lay down a gas plant and produce power with the requisite steadiness for less cost than he can produce the same power by means of steam engines, we are inclined to think he will adopt such gas plant, even if he is told that he might purchase other gas plant, say, 20 per cent. more economical, but not productive of equal regularity of turning. The large power user must have a certain steadiness of turning effort. This is his *sine quâ non*. Give him this and he will use that agent which gives it to him for least money. Offer him less regular turning at half the cost, and if he be a cotton spinner, he must decline the offer because he cannot produce an even yarn, and will also make much waste; if he be an electrician, he will have to decline again, because irregular turning shows itself in an unsteady light; if he be a water-

Digitized by Google

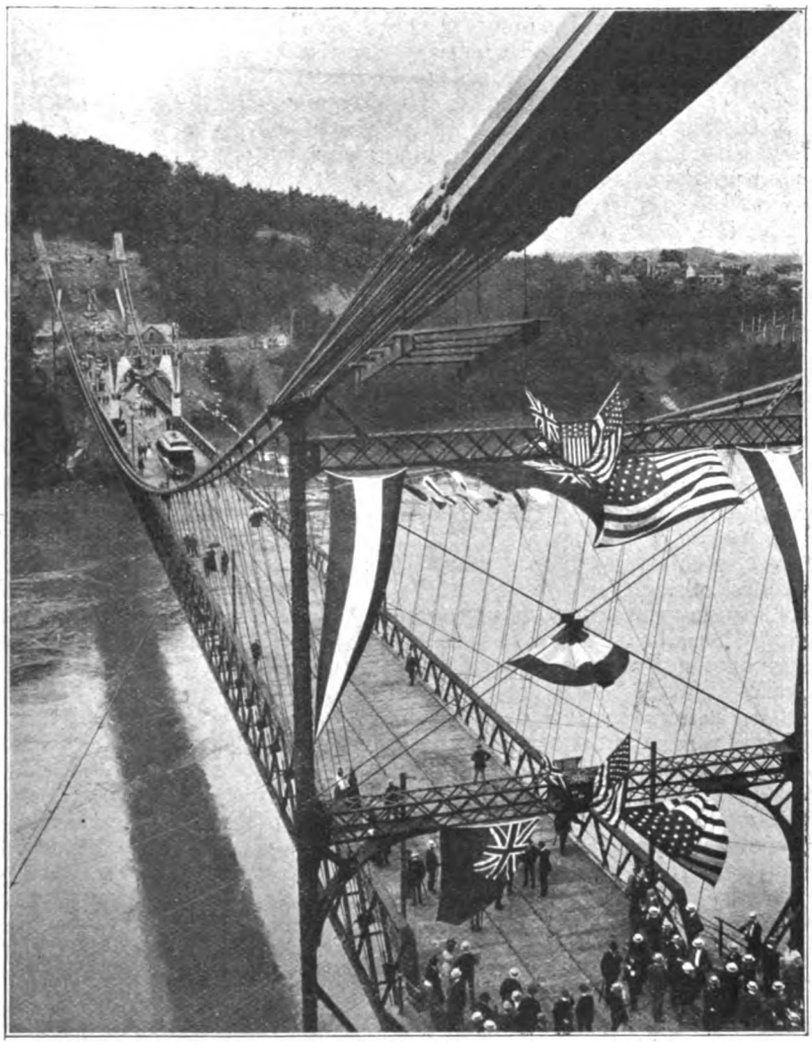
works engineer, he will accept because a few per cent. matters nothing in pumping, and it is worth while to save even 5 per cent. of fuel and accept a speed variation of, perhaps, double as much in doing so. It is claimed by the Westinghouse Company that the cost of power produced by gas engines fed by gas from a central gasworks, the engines being placed where now the rotary transformers are placed, should not exceed 50 per cent. of the cost of power produced by steam plant with high tension and step-down transformation. The suggestion is worth considering, but it should not be overlooked that if producer gas be intended, its volume per unit of capacity is very considerable, and a large gas engine will demand a gas main of correspondingly large capacity.

Natural gas will be consumed in a Westinghouse engine at the rate of 10½ to 12 cubic feet per H.P.-hour. It must be remembered that this gas is very rich; it has a calorific value of 1,000 B.T.U. per cubic foot; it is thus about tenfold richer than producer gas. Taking the case of an engine of 1,000 H.P., the consumption being 10 cubic feet of natural gas per H.P.-hour, we have no less than 100,000 cubic feet of producer gas to be conveyed to the engine. For argument, we will assume a velocity of flow of 100 feet per second. The engine is using 1,666 cubic feet per minute, or, say, 28 feet per second, so that the pipe area must be nearly 36 square inches. Thus each 1,000-H.P. engine would require a supply pipe 6 inches square, and for gas at low pressure square pipes would be quite suitable. According to Unwin, a desirable initial velocity of flow is 45 feet per second, at which velocity an initial pressure of 16·71 lbs. per square inch will transmit 31,815 cubic feet of gas per hour through a 6-inch round pipe 5,000 feet long, a rate less than half we have assumed above. Obviously, therefore, the question of gas transmission is of some importance, though the laying of a 6-inch pipe is not expensive, and 500 H.P., which could be carried by it, according to Unwin, is no small power at a sub-station. Considering the cheapness of gas-power under modern conditions there appears every reason to anticipate a considerable use of gas engines in the near future, if only gas engine makers will give an engine of sufficient regularity of turning effort as the Westinghouse Company now propose to do, and as any of our English makers are at full liberty to do if they will accept the system. Is it not better to use 1 lb. of coal by gas power than 2 lbs. by steam power? Yet the latter is adhered to, because when using its 1 lb. of coal the gas engine is not at its best. It is clear that if economy is specially desirable the gas engine must be worked as closely to its maximum duty as is consistent with certainty of action. If hit-and-miss governing be retained for its economy then must it be considered—we refer here to power purposes only, and more particularly to traction work—whether the voltage variation, which goes with economy of gas, can be permitted. The question is very much one for compromise between the best economy, steady turning and voltage, and fly-wheel weight.

THE NIAGARA SUSPENSION BRIDGE.

THE new electric railway suspension bridge of the Lewiston Connecting Bridge Company and the Queenston Heights Bridge Company, now controlled by the International Traction Company, was formally opened to the public on Friday, July 21st, in the presence of a notable assemblage of guests. Invitations of an elaborate character were issued by Hon. W. Caryl Ely, president of the International Traction Company, and these had the Stars and Stripes and the Union Jack in colours at the top.

Electric cars are now running across the bridge, but, says our correspondent, the belt line, of which the new structure is to be a link, has not yet been inaugurated, owing to the lack of connection on the New York side with the upper steel arch. This connection will be made as soon as the Commissioners of the New York State reservation grant the necessary right. The new bridge has a cable span of 1,040 feet, and a suspended span of 800 feet. It is 25 feet wide, and a single track for electric cars is laid through the centre of the floor. It is expected that



THE NIAGARA SUSPENSION BRIDGE.

all the cars of the Niagara region will be fitted so that they can make the round trip. On the day of the opening the structure was beautifully decorated from end to end, forming a magnificent scene. The American and British flags waved at both ends, and both were cheered to the echo.

WHAT'S A' THE STEER, KIMMER?

So far as we can gather from the local press and other sources, the Glasgow hubbub is, as the *Evening Times* dubs it, a case of "first she would, and then she wouldn't."

If our information is correct, the electrical adviser to the Tramway Committee was commissioned to draw up a general specification, so that all engine makers would be free to tender on their own standards, but for the purpose of assisting many British firms, the leading dimensions of the principal parts were set forth, qualified by the statement that these dimensions were not insisted upon.

Messrs. E. P. Allis and one English firm tendered to these

Digitized by Google

dimensions, but the other makers varied greatly therefrom and from one another.

We understand that the E. P. Allis Company were considered to have sent in the best tender, both as to design, weight, guarantees as to efficiency, &c., and delivery, with one exception to this latter point. Messrs. D. Stewart & Co. could have delivered in the quickest time, but as their tender was only for about half the sum quoted by the Allis people, there was probably some misconception on the part of these contractors as to the nature of the specification.

We believe Messrs. Musgrave & Sons were well in the running for design and efficiency, but required 2½ years to complete, as against the 20 months of Allis.

Messrs. Stewart have apparently taken some decided steps over the matter, and the upshot of the whole thing is, that the Council has decided that a new specification be issued.

This seems hardly just to makers who have already tendered on a clear understanding of the requirements, since the Glasgow firm now knows what those contractors, whose estimates were in order, will again tender upon, and also their prices, and nobody seems to have thought that a similar course should be adopted with regard to the generators as well.

En passant, we may say that a good illustration of the Allis type of engine was given in the ELECTRICAL REVIEW for March 4th, 1898, but we have but little information on this side as to what renders American engines so superior to those of English manufacture for traction work.

During the discussion which followed the reading of Mr. Cuningham's recent paper on "Mechanical Traction by Electricity" before the Institution of Civil Engineers, considerable divergence of opinion was manifested as to the relative advantages of high speed and low speed engines for traction work, some of those taking part in the discussion manifesting a preference for low speed, others for high speed, and a third section stating that they used either type indifferently.

For our own part, we see no reason why the high speed of revolution which has become such a leading feature in English lighting practice should not be equally useful in traction work.

In the first place, the quick revolution engine is invariably a vertical, or, rather, inverted engine, whilst the slow speed engine, or, at any rate, the slow speed engine which has been sent over here from America is as invariably a horizontal one.

We are sure that there is no necessity for us to dilate on the many points of advantage which the vertical engine has over the horizontal type. It is quite sufficient to remind our readers that 30 years ago horizontal engines were common in marine practice, and that to-day the vertical type is universal, and that, moreover, in central station practice the same tendency has been manifested. We could instance numerous electric light stations which have been started with slow speed horizontals, but continued with vertical engines at more or less high speed of revolutions.

There is too much tendency on the part of those who have not the necessary ability to think for themselves to accept the view that the American practice is bound to be right because of the extensive experience they have had in matters connected with electric traction on the other side of the Atlantic. But is this necessarily so? We may remind our readers that in the States they were going on with belt drive and even using countershafts long after direct coupling had been recognised as the best practice and become of almost universal application here. We have no doubt but that in the States, as here, the vertical type of engine will become standard for traction work, and that the speed of revolution will be materially increased in the near future.

At present we take it that the type of engine which is being offered by the American builders as the best for traction work is either a tandem compound horizontal single-crank, with the generator at the side, as at Glasgow and Bristol, or a compound side-by-side double-crank, with the generator between, as for the Central London Railway. How does such an engine compare with those previously described at the Waterloo and City station, for instance, as representing English practice?

We have already pointed out the great advantage the vertical quick revolution engine offers in the way of space occupied. No doubt the experience at some of the lighting stations we know of will yet be repeated in connection with some of the power stations for traction work under conditions somewhat as follows:—

The necessity for additional plant is forcing itself upon the attention of the engineer, his station has been built in, and land for extension is unobtainable; it is necessary, therefore, to make the most of such area as he has left, or otherwise to incur the very considerable outlay involved in building an additional station elsewhere. Under these circumstances, although he may be prepossessed in favour of low speed engines, he succumbs to the logic of facts, and goes in for high speed sets.

We know of at least one important traction station at the present time where it is actually in contemplation to fill up the spaces between the existing low speed sets with a high speed set of three times the power of those originally installed.

Of course, with the reduced ground area, there is the smaller building to cover it, and lighter travelling crane of less span required. The reciprocating parts of the quick revolution sets are so much less massive and cumbersome than the similar parts of the low speed engine, parts which, in the quick revolution engine, can be easily handled by one man; in the other engine they require a crane and a man to work it before they can be moved. Compare, for instance, the size of the L.P. cylinder at the Waterloo and City station with that at the Glasgow station. Although the Glasgow engine is of approximately the same power the L.P. cylinder there is 24 diameter × 24 stroke against 14 diameter and 9 stroke at the Waterloo and City station. The disparity is startling, and when it is considered further what such a large piston involves in the way of load on the bearings and the much greater impact there will be on the crank pins, particularly if a load is suddenly thrown on when near the end of the stroke, it is clear that all the advantages do not lie with the low speed engine, bearing in mind that the piston speed of the so-called low speed engine may be, and often is, higher than that of its quick revolution rival, and that the impact depends on the piston speed and not on the speed of revolution.

Following on the large L.P. piston, it is not surprising to find that the American engine is distinguished by a large fly-wheel—in fact, for such an engine a large fly-wheel is a necessity if anything like even turning is to be had.

The fly-wheel performs a double function—first, to maintain a uniform angular velocity during each revolution; secondly, to serve as a reservoir of energy to meet the momentary variations in the load characteristic of the traction load diagram.

So far as the first of these functions is concerned, the Waterloo and City engine has, of course, an enormous advantage. A three-crank engine with a complete engine on each crank is the nearest possible approach to absolutely even turning, short of a steam turbine.

The American engine, with its single crank, is the reverse of this. Careful calculations we have made have shown that to attain the same degree of even turning with the Glasgow engine, as with the Waterloo and City set, the fly-wheel for engines of the same power would need to be 16 times as heavy.

The large fly-wheel is, of course, useful as a store of energy, but when the enormous dimensions and weights of the fly-wheels on some of the American engines are considered, one is constrained to consider whether the same result could not be obtained with something less. Take, for instance, the fly-wheels of the engines at the Brooklyn power station, particulars of which will be found in the *Proceedings of the Institution of Civil Engineers* for 1895-6, these being communicated during the discussion following Mr. Cuningham's paper on the Montreal Street Tramways. Fly-wheels 24 feet in diameter, and weighing 65 tons, for engines of 2,000 H.P., and working in conjunction with armatures 10 feet in diameter, and weighing 27 tons, are of truly Herculean proportions.

We estimate from the particulars given that the kinetic energy will not fall very short of 4½ foot-tons per E.H.P., the similar figure for the Waterloo and City station being 2½ foot-tons, and the perfection of governing attained shows that even this may be reduced for the future.

We have always understood that the close regulation on which American engine builders plume themselves was due

Digitized by Google

to the perfection of their automatic expansion governors, but it would seem that the immense fly-wheel effects they use have more to do with it than the automatic expansion.

Unfortunately, too, these large fly-wheels have an awkward knack of going to pieces when least expected, with results worse than a boiler explosion; in fact, one might almost as well have a powder magazine in the engine room as some of the American engines, from the sensational narratives which are received from the other side from time to time.

We have seen some wonderful devices designed to meet this tendency of the fly-wheels to distribute themselves over the neighbourhood, but it does not seem to occur to our cousins across the water to alter the design of their engines, and so avoid the use of such monstrosities altogether.

The English type of engine for traction purposes is generally self-lubricating, which is a decided point of advantage; there is no running about with oil cans, careful adjustment of oil syphons, lynx-eyed supervision of numerous oil pipes to see that every bearing is getting its proper quantity of oil, and not too much of it either, no feeling the bearings at frequent intervals as with the low speed engines. This naturally results in a reduced cost for attendance. It is not unusual to enter a quick revolution station and find one man in charge of three or four 500-H.P. engines, but no one would think of running low speed sets of the same power with less than one man to each.

With respect to oil consumption, this again is in favour of the quick revolution type. The same oil is used over and over again, with the result that the consumption is reduced to a figure which is surprisingly low, and not only does the low speed or semi-high speed open engine use a great deal more oil, but the oil is thrown about the engine room with consequent discomfort and mess. Specifications for open engines used to read "Engines of the enclosed type will also be considered." It is now common to find a paragraph reading as follows:—"The engines must be of an enclosed or cased-in pattern so as to be clean running and to avoid throwing oil about the engine room."

Returning to Glasgow and its troubles, we may now consider what is likely to be the impression amongst engineers throughout the kingdom, since American firms have also carried off (if the Tramway Committee's recommendation is approved) three-phase generators, auxiliary generators, exciter generators, transformers and rotary converters, and boosters, to the tune of well over £100,000.

A consulting engineer is appointed to advise the Corporation at a fee not exceeding £10,000, whatever the capital expenditure. Presumably the object in view in making such an appointment is the saving of money by securing the best advice, so as to avoid, on the one hand, the risk of getting the work into the hands of incompetent contractors, who would land the Corporation in failure, and, on the other, to prevent paying through the nose to competent firms. If, however, the consulting engineer soars away over the heads of eminent engine builders, such as Hick, Hargreaves and Co., and Messrs. Musgrave & Sons, not to mention others, and recommends a higher American offer because the trans-Atlantic firm knows all about the work, having built so many similar engines before, does it not seem that money might have been saved by simply going in the first instance to a few of the best known American makers and placing oneself in their hands, without engaging an expensive consulting engineer at all?

The tramway department possesses a keen, shrewd, and able business man in Mr. John Young as general manager, an excellent and thoroughly practical engineer in Mr. Clark, and a perfectly competent and experienced electrical engineer in Mr. Le Rossignol.

These gentlemen were surely able to put the requirements of the department in such form that competitive offers could have been obtained from those firms which are known to have carried out such work before, and they would have had no difficulty in deciding to order all the dynamos from the British Thomson-Houston Company, the rotary converters and transformers from the Westinghouse Company, and the main engines from E. P. Allis & Co. The prices, probably, would not have been more than at present, and the consulting fee would have been saved.

We do not assert that this would have been the wisest course to adopt, but we do think that after employing a gentleman of such eminence as Mr. Parshall to draw up a specification, English engineers should have had no difficulty in complying with it; that this was by no means the case is evidenced by the letter of Messrs. Hick, Hargreaves & Co., which we publish on another page, although the E. P. Allis Co. contends that it contained nothing but the results of the best accepted practice. If everything had been plain sailing, and the American offers turned out lower with more speedy delivery, there would have been an end of the matter, but if the estimates of competent English builders are below those of the Americans, how is it that the expert is still obliged to advise the acceptance of the American offer at a much higher price?

What, in the eyes of the impartial observer, seems to have been done—and this is borne out by the Glasgow *Evening Times*—was to issue a specification with very little more than a general outline in it, and then a list of suggestions of what would be considered satisfactory, this list, however, not forming part of the specification, as there was no desire to hamper engine builders by tying them down to any particular pattern.

Quoting from the *Evening Times*, "Mr. Parshall, in his reports, pointed out that he had strongly hoped that some British engine maker could rise on this occasion and tender on an engine in all ways suited for electrical traction work. It was with the view to assist them in this direction that he gave dimensions and particulars in the specification. He should much prefer to be able to recommend the product of some first-class British firm, since he was alive to the feeling against engineers who recommended foreign-made apparatus. In the present case he had no alternative to recommending anything but the Allis engine. It was best for their purposes, the price was not unreasonable for what they proposed to supply, and this could be considered quite apart from the fact that they had greater experience than any other firm, and could supply what was required with absolute certainty, and without constructing anything that was new to them."

When the tenders were in, the process adopted seems to have been, judging from Mr. Paton's exhaustive comparative comments at the Council meeting, to take the Allis engine as the specification and judge all the others by it, condemning them in every detail wherein they differed from it.

A significant remark was that of Bailie King, who said that if anyone had given reasons for taking back the minute which was before the meeting, Bailie Paton himself had done so, when he stated that if Mr. Parshall drew out specifications for an engine, he could only draw one out for an engine such as the Allis people made.

We have tried to ventilate this very important subject, important alike to the English engineering industry and to the Corporation of Glasgow, with a mind free from bias, and we respect the sentiments of our evening contemporary which concluded its editorial comments with the following:—"If we must have the Corporation work done by purely British or purely Glasgow contractors, then the conditions of contract should be drawn out accordingly. That would be bad business, but it would certainly be more dignified than the system of inviting outsiders to tender and then searching for a loophole of escape. The city must above all things preserve its reputation for fair dealing."

One thing is quite certain—the Glasgow Corporation has perfect freedom to seek the best machinery in the market, and if, in the opinion of their expert, who, presumably, has an intimate knowledge of all and everything connected with the best electric traction practice, the plant is not forthcoming here, but is available and ready to hand in the States, he is within his rights in advising his clients to adopt a course which is based on the results of his own unique experience. If any blame attaches to anybody, surely it should rest from the beginning on the shoulders of the Tramway Committee.

We shall probably refer to this matter again in our next issue, when we hope to give our own opinion on the manner of drawing up the specification, which we have seen only since this article was written.

Presentation.—Mr. C. A. L. Prüsmann, who has left the Bradford electricity works, where he was assistant electrical engineer, to take up a chief engineership at Doncaster, was last Friday presented with a photograph of the members of the department, an illuminated address, and a travelling bag and dressing case, by the members of the staff at Bradford.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1899.

Compiled expressly for this journal by W. P. Thompson & Co., Electrical Patent Agents, 322, High Holborn, London, W.C., and at Liverpool, Manchester, and Birmingham, to whom all inquiries should be addressed.

16,094. "A watchman's electrical tell-tale system." A. Eckstein and H. J. Coates. Dated August 8th.

16,132. "Improvements in method of and means for inducing and controlling magnetic circuits." The British Thomson-Houston Company, Limited. (C. P. Steinmetz, United States.) Dated August 8th. (Complete.)

16,133. "Improvements in alternating electric current motors." The British Thomson-Houston Company, Limited. (C. P. Steinmetz, United States.) Dated August 8th. (Complete.)

16,140. "Electrical resistances and heating bodies composed of metallic oxides." V. I. Feeny. (Allgemeine Elektricitats Gesellschaft, Germany.) Dated August 8th. (Complete.)

16,167. "Improvements in or relating to switches for electric traction systems." H. O. Joedicke. Dated August 8th. (Complete.)

16,175. "Improvements in and relating to electric batteries." C. Lievetus. Dated August 9th.

16,191. "Safety guides for trolleys used in overhead electric traction." A. W. Murray. Dated August 9th.

16,198. "Improvements in and connected with multiple switchboards." H. Oppenheimer. (Actiengesellschaft, Mix & Genest, Germany.) Dated August 9th.

16,199. "Improvements in and connected with switches for high voltage." H. Oppenheimer. (Actiengesellschaft, Mix & Genest, Germany.) Dated August 9th.

16,200. "Improvements in and connected with lampholders." H. Oppenheimer. (Actiengesellschaft, Mix & Genest, Germany.) Dated August 9th.

16,210. "Improvements in the manufacture of thin tubes or sheets of copper or other metal by electro-deposition." S. O. Cowper-Coles. Dated August 9th.

16,215. "Improvements in electrolytic baths." W. Walker, jun., F. R. Wilkins, J. Lones, and J. Lones. Dated August 9th.

16,225. "Improvements in conduits for laying electric cables." W. H. Nichols and W. T. Henley's Telegraph Works Company, Limited. Dated August 9th.

16,247. "A new material adapted for electrical insulation and also for many purposes for which ebonite, wood, and such like materials are used." A. Smith. Dated August 9th. (Complete.)

16,250. "Manufacture of colouring matters and their reduction products by electrolysis." R. M. Salher. Dated August 9th.

16,267. "Improvements in electrical apparatus for sorting articles according to one of their dimensions." W. H. Lock and J. J. Milner. Dated August 10th.

16,285. "Improvements in plugs for telephone switchboards." E. D. Pearmain. Dated August 10th.

16,290. "An apparatus for the temporary closing of an electric circuit-current by means of Herz's undulations." J. Levy. Dated August 10th. (Complete.)

16,293. "Improvements in the manufacture of leaden plates for secondary batteries or accumulators, and in moulds and tools to be used in such manufacture." P. J. Davies. Dated August 10th.

16,300. "Improvements in safety fuses for electric circuits." E. T. Goslin. Dated August 9th.

16,308. "An improved operating device for electric bells and house-telegraph signals." F. Schuchhardt. Dated August 10th. (Complete.)

16,311. "Improvements in or connected with dry core electrical cables." H. Savage and W. T. Henley's Telegraph Works Company, Limited. Dated August 10th.

16,330. "Improvements in switches for connecting electric machinery." W. F. Jones. Dated August 11th.

16,336. "An apparatus for controlling the supply of electricity." W. L. Hardman. Dated August 11th.

16,350. "A magnetic needle-threader." M. Molitar and F. Kern. Dated August 11th. (Complete.

16,352. "Improved system of telegraphy and transmission of currents of electricity." F. Bedell. Dated August 11th. (Complete.)

16,368. "Duplex electrical alarm." A. R. Warden and A. Hunter. Dated August 11th.

16,373. "Improvements in vibrating switches or contact breakers for induction coils, bells, and the like." J. Burns. Dated August 11th. (Complete.)

16,382. "Improvements in connection with spindles and the driving of the same by electricity.' J. G. Lorrain. (H. B. Sawyer and R. Robb, United States.) Dated August 11th.

16,387. "Improvements in brush-holders for electric machines." S. H. Short. Dated August 11th. (Complete.)

16,395. "A new and improved arrangement for controlling electric elevators." E. A. Wahlström. Dated August 11th.

16,410. "Improvements in electric arc lamps." A. Eckstein and A. E. Angold. Dated August 12th.

16,417. "Improvements relating to jointing electric cables." R. H. Hayne. Dated August 12th.

16,439. "Improvements in or relating to arc lamps." G. C. Dymond, of the firm of W. P. Thompson & Co. Dated August 12th. (Complete.)

16,444. "A method of receiving telegraph signals as displayed or photographed by magnetically deflected cathode rays." Siemens Bros. & Co., Ltd. (Siemens & Halske, Actiengesellschaft, Germany.) Dated August 12th.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson and Co., 322, High Holborn, W.C., and at Liverpool, Manchester, and Birmingham, price, post free, 9d. (in stamps).

1897.

12,714. "An improved insulating and carrying frame for accumulator electrodes." F. W. Schneider. Dated May 22nd, 1897. Relates to framework for insulating and supporting cylindrical or trough-shaped electrodes in vehicles and other places. It consists of perforated plates of hard rubber connected by bolts on which, between the plates, are fitted rubber sleeves. The bolts support the electrodes. 2 claims.

12,820. "Improvements in transforming continuous electric currents." A. Muller and H. Tudor. Dated May 24th, 1897. Relates to the transformation of continuous currents by means of secondary batteries. The batteries are divided into groups which are connected to the sections of a commutator, and an equalising battery is placed in shunt with the generator or translator. The conductors are connected to the brushes of a commutator driven by a motor. The secondary battery is divided into groups which are connected to the sections of the inner ring of the commutator. A high tension current is thus obtained in the conductors. To obtain a low tension current for the consumers, a similar arrangement of apparatus is employed, but the lamps, &c., take the place of the generator. To prevent sparking at the commutator, a separate contact-breaker is employed. It comprises a disc fitted with segments corresponding to the contacts of the commutator. Methods of arranging both batteries in groups to obtain any desired ratio of transformation are also described. 2 claims.

12,902. "Improvements in series parallel controllers for electric motors." P. V. McMahon. Dated May 25th, 1897. Consists of switching gear, of the kind known as series parallel controllers, for starting motors in series and placing them in parallel after a certain speed has been attained, as in the case of an electric locomotive or other electrically-propelled vehicle. An ordinary rheostat or starting switch, with contacts which are preferably circular, but may be rectilinear or of other convenient design, and a separate paralleling switch, with contacts mounted on the fixed insulating plate, are mounted on the same base and operated by the same handle. The brushes or the contact fingers of the paralleling switch are mounted on an insulating disc or arm, which is free of the handle of the rheostat switch, except during a certain portion of the movement of the latter towards each end of its throw when the projections engage with each other. It results that the change from parallel to series or *vice versâ* cannot be made without first putting in or out of circuit, as the case may be, the necessary resistances for preventing sparking. 2 claims.

12,942A. "Improvements in electrical ignition apparatus for explosion engines and for other purposes." C. M. Johnston. Dated May 25th, 1897. The sparking terminals in the cylinder of an explosion engine are connected with the secondary circuit of an induction coil. The primary circuit containing the condenser is excited by a battery, which is charged by a generator; it is broken and completed at the proper time by a switch. A large coil may be used without the condenser, or a large condenser without the coil. 8 claims.

12,945. "An improved electric arc lamp." F. Fouquet and J. W. Keys. Dated May 25th, 1897. Relates to arc lamps. A clockwork lamp, for continuous or alternating current at constant potential, is constructed as described. The upper carbon holder is attached to a long rod and the lower one to a short rod sliding in guide tubes. The rods are attached to the ends of a cord, which passes over two pulleys and under a pulley. The pulleys are carried by a lever at unequal distances from its fulcrum. The longer end of the lever supporting the lower carbon is drawn down by a spring separating the carbons when the lamp is not in use. The shorter end of the lever carries two cores within the two shunt coils of a fixed electro-magnet. The pulley turns on a stationary axis, and drives an oscillating balance when a pin on this is released by a notched plate on an arm of the lever by the action of the shunt magnet. The motion of the lever is limited by screws, and the tension of the spring is adjusted by a lever and screw. 1 claim.

14,010. "Improvements in electric motors for driving motor carriages, winches, and stationary machinery, also a portable motor for rotary hair and cleaning brushes for milling, drilling, and other purposes." H. W. Headlang. Dated June 19th, 1897. Relates to electric motors for driving motor carriages, tram-cars, winches, and stationary machinery; also, in a portable form, for drilling, milling, rock and blasting drills, rotary hair and cleaning brushes, dentists' tools and other purposes. The armature is fixed on its shaft, and the field magnets are carried by a casing running loosely on the shaft, and the shaft and casing are connected by bevel, skew, or worm gearing with one or more intermediate shafts which transmit the power. In a form shown, the armature shaft and field-magnet casing carry bevel-wheels which gear with bevel pinions on an intermediate shaft which by means of a worm may transmit the power to a motor-car axle. A second shaft and axle may be driven in a similar manner. The armature shafts and driven shafts are supported in ball bearings in a frame. This frame may be pivotally suspended from the underside of a motor-carriage frame. When employing worm gearing, worms of opposite pitch on the field-magnet hub and armature shaft gear with two parallel, which they drive in the same direction. The form of the supporting-frame may be variously modified. 6 claims.

14,023. "Improvements in alternate current motors." A. Semmes. Dated June 19th, 1897. To facilitate the starting of alternating current motors, the field-magnet is provided with two sets of windings, one of which is adapted to produce a larger number of poles than the other. The former is employed when starting the motor, after which it is switched out and the other brought into circuit for continuous running. A field magnet is shown, the running winding of which is composed of four coils in conjunction with their usual starting coils, while the other winding is composed of eight coils together with their starting coils. The armature may be wound with a single winding having a resistance adapted to the running winding of the field magnet; or it may be wound with two windings, one of which is operative at starting and the other in continuous running. 4 claims.

15,011. "Improvements in brush-holders for dynamo electric machines." J. H. Yearsley. Dated June 22nd, 1897. Brush-holders.—The brush is contained in a box and is pressed against the commutator by a pair of arms pivoted to a bracket on the box, and united by a bridge-piece acted on by a spring. The tension of the spring can be adjusted by means of a screw with nuts. 2 claims.

15,239. "An improved manufacture of electrical resistances." J. F. Bachmann, A. Vogt, J. Kirchner, A. Konig, C. C. Weiner, and A. Jorg. Dated June 25th, 1897. Resistances are made of mixtures of powdered conducting and non-conducting or badly constructed materials, which may be rendered plastic or liquid and moulded or cast to any desired forms, and dried or baked, or may be used as powders. The conducting material may be formed in the baking by using decomposable ingredients, such as tar, sugar, or metallic compounds, or may be powdered metal or carbon. The other materials may be aluminia, gypsum, cement, clay, &c., and binding materials, such as water, glass, zinc, chloride, sugar, gum, &c. The resistances may be hardened with alum solution, and may be glazed or otherwise protected. Such resistances may be moulded in the form of receptacles which can be electrically heated for cooking or other purposes; the powders may be enclosed between a pot and an inner receptacle. 1 claim.

15,288. "Improvements in electric arc lamps." L. Bardon. Dated June 26th, 1897. Relates to lamps. The regulating mechanism of a brake lamp for continuous or alternating current at constant potential is shown. The carbon holders, of which the upper is the heavier, are hung by pulleys in loops of a cord; this is attached at one end to the top plate of the lamp, passes round three pulleys on fixed supports, and is attached at the other end to a pivoted regulating lever; the third pulley is attached to a brake-wheel. The lever is bent to carry cores over two shunt coils, and is linked to a counterweighted lever. The wheel is acted on by a brake lever when this is not raised by the action of the coils on the regulating lever and a contact piece linked to it. On starting the lamp the cores hold up the brake until the greater weight of the upper carbon holder places the carbons in contact; they then allow the lever to move so that the brake is applied and the lower carbon lowered, an arc being thus struck. 3 claims.

26,660. "An improved electric arc lamp." R. W. L. Holsten and the Elektrische Bogenlampenfabrik Naeck and Holsten Gesellschaft mit beschrankter Haftung. Dated November 15th, 1897. Relates to arc lamps.—A weighted upper-carbon-holder and a lower one, not shown, are suspended by a chain on a chain-wheel and a pulley. The wheel is geared to a rotary fly in a fixed frame and normally is prevented from rotating by contact of the fly with a finger, supported by a feed-lever which is pivoted and acted on by a spring. The pulley is carried by a striking lever pivoted at and acted on by a spring. The levers carry cores near a shunt solenoid. When current is supplied, the lower carbon is raised by the action of the core and pulley, and an arm of the lever tilts the finger so that the fly is released, and the carbons move together; they short-circuit the solenoid, which drops the core, so that the lower carbon strikes the arc. For continuous current, the solenoid and cores may be replaced by an electro-magnet and armatures. 1 claim.

THE USE OF GAS AND ELECTRICITY.

SOME few weeks ago one of our building contemporaries, in summarising what is considered the peculiar condition of London gas affairs, stated that: "In spite of the increasing adoption of the electric light, the annual output of gas continues to increase, and has reached a volume almost inconceivable in its magnitude." The most pessimistic holder of gas shares could hardly fail to be favourably impressed with such a statement, and we feel sure that no member of the great rival industry would be sorry to learn that gas companies are generally having a good time. It is not long ago that orators on electrical subjects endeavoured to modify the scare among that section of the public interested in gas companies, by pointing out that wherever electricity had been adopted for lighting the gas company had gained in prosperity. If gas were used only for illuminating purposes, such a statement would soon cease to possess any significance, for it can hardly be doubted that the growing use of electricity must have had an appreciable effect on the consumption of gas for merely lighting purposes. It is not difficult, however, to ascertain the real cause of the continued prosperity of gas undertakings, for Mr. George Livesey, the chairman of the South Metropolitan Gas Company, declared in evidence before a Select Committee of the House of Commons that 50 per cent. of the gas sold by his company was used for purposes other than lighting. Unless some extraordinary changes take place in the method of utilising gas for illuminating purposes, electricity ought in the very nature of things to supplant it as a lighting agent; but what a long road to travel before we reach such a desirable consummation! At the present moment in some of the larger towns there is probably sold twenty times as much gas as electricity, and if such a demand were to be met by electrical works it would need a radical departure from the present system of carrying out extensions.

It is, of course, difficult to estimate precisely what effect the introduction of the Welsbach burner has had upon the electricity supply industry, for hitherto the only limit to the increased use of electricity has arisen from the difficulty in obtaining the necessary electrical machinery. In all probability the introduction of the incandescent burner has caused many people to retain gas, who otherwise would have adopted electric lighting, and it cannot be denied that it possesses some marked advantages. At the same time the disadvantages of the system are apparent, and in spite of the improvements effected from time to time, it cannot be expected to reach the pitch of perfection by providing a light that burns in a vacuum, and thus guarding against the vitiation of the atmosphere. The breakage of delicate mantles has still to be reckoned as part of the system, but according to our contemporary, other causes have tended to prevent the wider use of incandescent gas mantles, for we read that, "Owing to

Digitized by Google

the manner in which the incandescent burner and mantle business has been handled in this country, the cost of every mantle to the London gas consumer is some 300 per cent. higher (1s. instead of 3d.) than to consumers in certain Continental towns. Similarly, the prices charged for incandescent burners are, in this country, absurdly high. Ceaseless litigation, and what we must consider the over-capitalisation of a great company, is largely responsible for the fact that in past years London consumers of gas have paid far too heavily for incandescent gas appliances, and the friends of the gas industry will have cause to rejoice when the master patents expire, and mantles and burners can each be purchased for a few pence apiece." If our contemporary is correct in its views, the rivalry of the incandescent gas burner might have been a more formidable affair than it has proved; but one cannot help remarking that, in spite of the cheapness of gas mantles on the Continent, electricity undertakings there do not appear to have suffered to any great extent. Probably by the time the master patents of the gas burners expire, a form of incandescent electric lamp may have been evolved, which will ensure for electricity a continuance of past favours; we have already indicated the direction in which investigators are working.

It cannot be denied that of late years the gas companies have shown remarkable activity in developing the use of gas for heating and cooking purposes, and doubtless the greater portion of the 50 per cent. of which Mr. Livesey spoke goes in this direction. Both as a means of cooking and heating gas has proved itself to be an economical agent, and the hiring out of appliances has aided very materially in advancing this side of the business. With even greater facility electricity can be applied to similar purposes, and that the merits of electric heating are fairly widely appreciated is evident from the use that is made of electrical heating appliances. The electric heater itself is probably one of the most efficient devices in existence, but it is doubtful, under present systems of generation, whether it will ever achieve a popularity similar to that of gas. We are not unmindful of the fact that electric heating possesses the features of cleanliness, convenience, and facilities for regulation and control that render it unapproachable under certain conditions, but, unfortunately, it is likely to remain expensive for some time to come. Mr. Alton D. Adams, in investigating the various systems of heating, showed the total combustive energy which could be derived from different devices. Steam heat, with good boilers, gave 70 per cent., steam heat, with ordinary house boilers, 40 per cent., hot water heat, with ordinary house boilers, 40 per cent., heat from stoves, 30 per cent., and heat from electric heaters, 7 per cent. The unfavourable position occupied by electricity arises from the losses in the boiler, the steam engine and dynamo, and the conducting medium. As we have indicated, there are many directions in which electric heating might be used with advantage, and in some cooking operations where the cost of labour was high compared with the cost of heat, there might be a favourable field, but for general every-day use there does not appear to be any immediate prospect of electricity competing very seriously with gas.

Where electricity can be obtained for motive power purposes, there does not appear to be any great likelihood of its being ousted by gas, for gas motors have none of the facilities of starting or of regulation that are possessed by the electric motor.

There are certain directions, however, in which gas ought to have been used to a greater extent, that is, in the driving of electric generators. We are not unmindful of the splendid work that has been done in private installations, but we have rather in view the use of gas in driving large public electricity works. It is true that two or three of the public instances in which gas-driven electric generators have been employed, have been comparative failures, but the causes are clear, and if they are properly recognised by gas engine builders, similar troubles are not likely to occur again.

There are many electrical men who are convinced that the most economical method of distributing electricity through a town would be to place dynamos and gas engines at substations and utilise the gas from the street mains for driving purposes. Such a scheme has much to recommend it, but it is doubtful whether the modern gas company would appreciate it sufficiently to bring down the price of a gas to a point at which the experiment could be tried. There was a time, not far distant either, when the gas companies of this country, by adopting some such policy, could have controlled the future of electricity supply; they missed their opportunity and have had to face a competition, which, with the apparently limitless possibilities before electricity, is bound to become more severe from year to year.

Viscosity.—A discourse, given by Prof. H. S. Hele-Shaw at the Royal Institution seven months ago, on "The Motion of a Perfect Liquid," has at last, after many retardations and eddyings, trickled through to the press, and appears in the form of an illustrated article in the *Engineer*. We are first shown diagrams representing the stream lines in the case of water passing through channels of various forms, and the tumultuous conditions under which water moves when it has to dodge through sluices, or along narrow river beds. The effect of a widening in the waterway is next discussed, the inertia of the particles is considered, and we are led to see that the impact of the particles in the wider portion necessarily involves greater pressure in that part. By introducing colouring matter or air-bubbles into the water, bands appear, whose widths indicate the local velocities and pressures. Having then determined the pressure at every point of the liquid, the directions in which the particles are moving, and their velocity at every point, we may know, or may think we know, all about its motion. Unfortunately, at this juncture viscosity comes into the problem, and hence arise immense differences between the flow of an actual liquid and the behaviour of a so-called "perfect" liquid. Viscosity turns out to be the cause of half the troubles and all the sea-sickness of the universe, but with some compensations. If there were no viscosity there would be no waves raised by the wind, there would be no tidal flow, rivers would move with incredible velocity, and rain would fall in one big unhesitating drop.

Naming the Motor Carriage.—Let it not be thought that there is an end to the American controversy as to what we are to call a motor carriage. Mr. C. E. Woods, of Chicago, does not allow our contemporary, the New York *Electrical Review*, to have it all its own way, for, although to our namesake's mind the matter was settled once and for all, he suggests to the public in the American *Electrician* a name claimed to fulfil all requirements:—

> That is the name *autobaine*, which, translated, means automatic waggon, *baine* being derived from an old Greek word, meaning waggon; so we have for the name of the vehicle, *autobaine*, *autobainer*, as applied to a man operator, *autobainess*, as applied to a woman operator, and *autobaining* or *autobaineering* for the act of using the vehicle, in addition to which, this name is applicable to any kind or form of self-propelled vehicle.

THE GLASGOW CORPORATION CONTRACT.

Since our article of last week we have had the opportunity of perusing the specification of Mr. Parshall, which it will be remembered was issued as a guide, not as a binding specification. He states that he wished to allow the "fullest latitude" to contractors. Now, from the letters of the Allis Company and Messrs. Hick, Hargreaves & Co., it appears that the dimensions given by Mr. Parshall are some of the points in dispute. Though not forming a part of the obligatory specification, these dimensions are there, and may be assumed to represent Mr. Parshall's ideas of design. They are endorsed by the Allis Co. as the best practice. There are two alternatives in the specification, but both are for engines of 75 revolutions, 150 lbs. pressure, and for 2,500 KW. capacity. In each the stroke is the same, and it may be assumed that the cylinders should be the same. Yet in one case the H.P. cylinder is to be 42 inches diameter, in the other 44 inches. We do not think much of this discrepancy. H.P. cylinder proportions may be varied with little or no difference in economy. The difference, however, is there, and appears needless.

Two 60-inch L P. cylinders in one engine are assumed to be the equivalent of one 88-inch L.P. cylinder in the alternative. Is not this serious? Allowing for the rods, it amounts to almost exactly 8 per cent., and it is 8 per cent. the wrong way, for had any difference been made it should have been in the other direction.

Then, again, the diameter of the piston rods for 60-inch and for 88-inch cylinders is given as 10 inches. Is not this altogether wrong? When Messrs. Allis claim it as good practice, we feel inclined to ask them, Is this your practice? because if it is, your practice does not seem correct. At first we could hardly believe it was Messrs. Allis's practice, and were inclined to set down their letter as so much sheer bluff on this point. We must also say that Messrs. Hick, Hargreaves & Co. are perfectly correct in bringing up marine practice in large engines in respect of shaft sizes. The shaft stresses in a marine engine are much greater than in a traction engine. In marine practice, in heavy weather, the load varies from zero to a maximum with a suddenness equal to anything in traction work. The truth is, that far too much is, and has been, made of the stresses in traction work, and we would refer our readers to an article in another column, dealing with this point at some length. This supposed enormous engine stress has been worked for all it is worth in electric traction by American contractors. It may be perfectly true that the Americans have made their engines for traction work very much heavier than those they had been accustomed to construct, but we doubt whether American traction engines are so particularly substantial and strong as Messrs. Allis would have people believe. We very much doubt if they compare in strength with engines sent out by Messrs. Hick, Hargreaves & Co. to some of the Indian mills, engines very much larger than these Glasgow engines, and very considerably over what is necessary for 2,500 KW. The idea that American engines are so very heavy and substantial is quite a myth. Let us look about us at a few American engines in tramway work in such places as Stoke, Cork, Dudley, and Dublin. At Stoke there are some McIntosh & Seymour engines. They are not particularly substantial, according to our English ideas. At Dudley, some engines by another maker, Ball & Wood, have a distinctly light appearance, and like other American engines, lack the finish and neatness of English work. At Cork, another type of McIntosh and Seymour engine may be seen. Is it 200 or is 500 the number of joints and pins of that most fearful assemblage of valve gear? But, except for this, we do not think the engines can be called badly designed in respect of excessive weight, though, probably, the valve gear might be lightened a ton or two. At Dublin may be seen a vertical McIntosh and Seymour engine at the old Balls Pond station, and some fairly large Allis engines at the new station in course of erection at Ringsend. But surely Messrs. Allis do not wish to claim for these Ringsend engines any substantiality over English work! Messrs. Hick, Hargreaves & Co. wrote a perfectly courteous letter to the *Manchester Courier* and other papers, which we reproduced last week, and they did not sneer at their American rivals. The Allis Co. wrote in very questionable taste indeed, and endeavoured to imply inexperience and ignorance on the part of Messrs. Hick, Hargreaves and Co. It is a claim put forward by the Allis Co. that the valves of their engines are often placed by them in the heads of the cylinder to the great reduction of waste space. This is a good arrangement for horizontal engines if properly carried out, but it is not a monopoly, and is of very doubtful value in a vertical engine.

But to return to the specifications. Alternative designs were called for, the one with two, the other with one low pressure cylinder. It is usual, in asking prices for alternative schemes, to place the more desired plan first. We believe that, acting under this impression, the English firm tendered for the three-crank engines. If we are correctly informed, the American tender for the apparently secondary two-crank engine scheme appears to have been the one accepted. This is a point which may have arisen from Mr. Parshall's ignorance of custom, but it is one which, on the face of it, certainly calls for explanation. The Corporation of Glasgow are not noted for their courtesy in their dealings, but it passes all bounds that they should have invited Messrs. Hick, Hargreaves & Co. to meet them at a special interview to discuss tenders and then have refused to discuss the question of their tender. Mr. Parshall owes an explanation of this. He was advising the Corporation, and unless he can explain it, this extremely discourteous conduct will also be laid to his charge. It is admitted that Messrs. Hick, Hargreaves tendered for an engine of satisfactory weight. This disposes of the Allis Co.'s claim of special substance. It differed in detail, and it ought to have differed in detail from the Allis engine if this was so designed as Mr. Parshall's figures would appear to prove. Then the English tender was £20,000 less than Allis's, which disposes of their claim about competing at 3,000 miles distance. £20,000 is good pay for sending even a well-paid man round the world, while the carriage item from Milwaukee is probably less than what the Bolton firm would pay under the paralysing charges of the London and North-Western Railway.

The special features of the engines, such as the so-called emergency valves, are English in origin. The emergency valve is the knock-off motion of the factory engine, and there is nothing in the demands made that Messrs. Hick, Hargreaves & Co., or any other high-class engine maker, would not easily have filled. Even the boring out of crankshafts was first practised largely by the Bolton firm. In fact, throughout the specification there is nothing very abnormal, previous to the dimensions above referred to, which could not have been explained if it had been desired to afford explanation. What Mr. Parshall apparently wanted, and he might have plainly said so, was simply a vertical cross compound (two-cylinder) engine. It looks as if he made himself appear to want a three-crank engine, and having received a tender reluctantly decided to pay £20,000 more for the two-crank type. The engines he seemed to desire were of a type of which more have been made in Great Britain than in all the rest of the world put together. That they were to be used for traction work was a mere incident, unworthy of serious argument.

Taking into review the whole of the circumstances, it will probably be considered by many that there is strong evidence of a foregone conclusion. The Soho Works at Bolton may not be so large as the Milwaukee Works, but they are equal to making much larger engines than are required for those little 2,500-KW. sets. We know less of Messrs. Duncan, Stewart & Co., of Glasgow, who tendered at less than half the price accepted, but what we do know of that firm is to their credit. We have tested their engines and found them economical. The firm is well known as a rival of an eminent Manchester works in some departments of engineering, and is well able to carry out anything it may undertake, and to give good work even if its tender may appear low. The consulting engineer has practically specified for an ordinary Lancashire factory engine. The biggest cylinders in the primary alternative are 60 inches × 60 inches, the exact size, if we mistake not, of the single cylinder of the "Iron Duke," put down by Messrs. Hick, Hargreaves & Co. at Eagley Mill, near Bolton, about the year 1884. This engine has Corliss valves in the cylinder heads on Messrs. Hick, Hargreaves & Co.'s plan,

Digitized by Google

and resembles one half of the engine asked for by Mr. Parshall. He has stated that Messrs. Allis had guaranteed a lower steam consumption than any English firm. This statement, we believe, is not in accordance with fact. Messrs. Hick, Hargreaves & Co., says the *Engineer*, guaranteed 1½ lbs. less than the Allis people.

So much in disagreement with the methods of Mr. Parshall, and of Glasgow. On the other side, putting aside any thought of undue partiality, the Allis Company may properly complain, if they can do so courteously, that they have not been fairly treated. They gave in, it is said, a shorter time for completion than any English firm. This is something. But there is a doubt whether they would, or could, have kept to time, and we find that the penalty clause is usually not enforced. There are always some extenuating circumstances. We hear that American contractors are by no means so punctual in delivery as a few specially reported cases—*e.g.*, the Atbara Bridge—have led people to believe. There is quite considerable delay in delivery of American machinery, and we cannot think that the difference in time was so serious as to warrant the rejection of the English tender. It appears that the Allis Company accepted the dimensions of Mr. Parshall *in toto*; it would be interesting to know how he arrived at them. But this does not prove the Allis designs to be good. They are not considered good by firms fully their equal in experience. Given only as suggestions, and put *outside the specification in order not to hamper contractors*, the non-acceptance of Mr. Parshall's dimensions is counted against Messrs. Hick, Hargreaves & Co. for sin. While, therefore, the Allis Company may feel aggrieved, they must have known there would be an outcry against such shabby treatment as was meted out to Messrs. Hick, Hargreaves & Co. by the Committee in refusing to discuss their tender after specially inviting them to be present for that purpose. After all, when a committee travels widely with a view to inspect foreign tramways, and learns so little as to require to pay an outside fee of £10,000, much surprise need not be felt at any blundering they may be guilty of, for, look at the matter as one will, Glasgow has blundered. Its Tramway Committee has blundered headlong into this traction business. They have their own employés fully competent to have dealt with the matter, and they must have been fully alive to the fact that if they employed an American consulting engineer, he was extremely likely to be partial to America. In a case like this of Glasgow, the step was entirely unnecessary. We say nothing of the electrical plant at present, as the case may be less strong in this respect, but in the matter of large steam engines we do say that no American firm has yet produced better steam engines than are turned out in our English shops. As regards finish, the English engine is far better. In material generally, the English engine is fully abreast of its rival, while in the wearing quality of the cylinders, we possess an undoubted and considerable superiority. As regards finish, however, it is probable that neither in England nor America is it equal to that of some of the work done in Switzerland. Whatever may be the final outcome of this Glasgow business, we hope it may draw special attention to the great amount of work to be done in electrical traction. Our English firms are many of them very remiss in pushing work. We have called attention to the excessively disagreeable tone of the Allis Company's letter, but this is as nothing compared with one shown to us a few days ago from a firm of electrical contractors to large users of electrical plant. The tone of this was downright insolent. Busy engineers are very little better than members of the A.S.E. in their callous disregard of the feelings of their customers, and we are not surprised that insulted customers should sometimes go elsewhere. Because the Bolton firm in their correspondence show evidence of a now too rare courtesy and refinement, in marked contrast to the quips and sneers of their American rival, we all the more regret their unfair and churlish treatment at the hands of the Glasgow Committee.

We have read somewhere the usual sneer that, after all, Englishmen are not free traders. But this is not a question of free trade. A gift of £20,000 is to be made to a foreign firm for an article in no way superior to the home production.

There is no feeling against American goods in England, as is well known. We are content to take them on their merits in fair competition, and to welcome them. But this Glasgow business goes altogether beyond the fair limits of competition. Lest it be thought we have made too much of what we deem the faulty designs of Mr. Parshall, we would observe that in the three-crank engine the crank pins are respectively 12 inches, 16 inches, and 20 inches diameter, and between these cranks come shaft bearings of 22 and 24 inches, while beyond the third crank pin the shaft suddenly jumps up to 32 inches diameter, a size altogether out of the way in respect of torsion, and unnecessarily heavy for a wheel of only 98 tons (220,000 lbs.). There is to be a 32-inch bearing on each side of this 98-ton wheel. We may conclude that the space occupied by the fly-wheel is small. The wheel carries no ropes or belts, and only needs to be wide enough to give the weight. Probably its bearings are not a yard apart. A dozen years ago a 72-ton fly-wheel 30 feet diameter placed on a shaft 12 feet long from centre to centre of bearings was allowed a shaft 19 inches diameter at the bearings and 24 inches diameter under the wheel. This was ample; it allowed a bearing intensity considerably below 130 lbs. of the projected area of the bearings. In one bearing of the proposed Glasgow engine the bearing figure is as low as 52 lbs. If the shaft should be very strong anywhere in a traction engine it is between the wheel and the generator. If a 32-inch shaft neck is required to carry the work of the engine increased, say, to double stress beyond the fly-wheel, how big a shaft is needed for torsion between fly-wheel and engine? Obviously if both shafts are bored out with a 12-inch hole the diameter would be 26 inches, which would have been ample in place of the 32 inches. Then, again, if a piston rod of 10 inches diameter is ample for a 60-inch low pressure cylinder, how does Mr. Parshall justify the same diameter for a rod of equal length on a cylinder of over double the area? As regards the Allis Company's remarks on the 100-tons fly-wheel and its bearings, it matters nothing to what duty an engine is put; this cannot affect the bearing pressure on the journals in direct driving, and the sneers at Messrs. Hick, Hargreaves & Co. on this point are quite unnecessary. The figures given look like misproportions, and if they do represent the best American practice, then so much the worse for it. They do not meet with the approval of engineers on the Clyde, and, after all, and despite the disclaimer as to marine practice made by the American company, something may be conceded to men who have engined a *Lucania*.

Since this article was in print the matter has been again considered by the Tramway Committee; the result of their deliberations may be seen in our "Notes" columns.

THE LABOUR CLAUSE QUESTION.

It may, perhaps, be thought that we have harped upon this string somewhat frequently during recent months. Our excuse must be that we are painfully impressed with the very serious consequences which municipal labour clauses must have upon the electrical engineering industry of this country unless a strong braking influence is speedily brought to bear upon the policy of labour interference.

The extent to which this intermeddling is carried on was shown very clearly in the statements contained in a Parliamentary return issued some months ago and published in abstracted form in the Electrical Review for *May 19th*, 1899. The data there collected may be re-studied with great profit at the present moment. Recognising at that date how general the practice was becoming, we stated that manufacturers would be compelled to offer combined resistance to it. Although, for certain reasons, one or two firms stood outside the combination, those who came to an understanding formed a very solid square, with the satisfactory results already recorded in the cases of West Ham and Sheffield electrical contracts.

But these are only two out of hundreds of Councils which may be expected to cause trouble within the next few years, considering that the great extension of electrical development is proceeding concurrently with the extension of the dictatorial policy. It is pretty certain that there are stormy times ahead for employers who determine not to submit to trade union interference as practised by local authorities.

Digitized by Google

We hope, nevertheless, that they will stand firm, and insist upon the rights of capital being not only recognised but respected.

It seems to point to something rotten in the electoral system of this country, that an intolerable system of trade union wire-pulling should control the placing of nearly all municipal contracts. The fact is, that rational people are few and far between on local government bodies. The rights of the working man, whose rates are very low, are too often considered at the expense of the large ratepayer. But this part of the question is too political to enter into at length here, particularly as it is hopeless to look for any immediate improvement in the *personnel* of our Councils. It seems that the quality of the article supplied, efficiency, price, and delivery are of less consequence to the municipal member than the insertion of clauses to determine what wages the contractor shall pay his employés, and to impose onerous and unnecessary conditions as to hours of work and the manner of conducting the factory. We say unnecessary conditions because there is no such thing as sweating existing in the electrical engineering trades, and, generally speaking, the wages of workmen are excellent for the class of work performed. Were there no disorganising combination of the trade union class, employers would, we believe, be able to look after the best interests of their workmen by giving them freer chances of promotion than is possible under the restrictive *régime* of union management.

We fail to see what legal right local authorities possess to dabble in trade unionism at all. It seems out of their province altogether. If a council wants certain apparatus supplied, so long as it gets a good thing at a fair price it should have no power to interfere with the wages that are paid or the hours that are worked, unless there is clear evidence that sweating is carried on at the particular works in question. A higher contract price is an obvious corollary of the imposition of restrictive conditions. Additional outlay, trouble, and anxiety must be paid for somehow, and all contractors, in sending in estimates, will take good care that there is sufficient margin allowed for it. Therefore a municipal body not only pays for the actual goods supplied, or the work done, but it pays the contractor a sort of gratuity to fall in with its whims and fancies as to labour employment. We are tempted to ask whether the Local Government Board quite appreciates the position in which it is placed by this state of affairs. This body is very ready to come down upon local authorities when an extra £10 or £100 has been spent in an irregular way, but the matter under consideration at the moment seems to us to call far louder for redress. The Local Government Board holds its inquiries regarding proposals to raise monies for certain public works. In the course of the hearing it transpires that a contract is to be given to So-and-so at, say, £10,000. There is no question raised as to what percentage of this sum is included by the tenderer as insurance against the probable effects of labour clauses. It is a point that might be raised with considerable advantage, and we think it would be a revelation to the ratepayers, who may be filled with the most sympathetic regard for the working classes, until they have it brought home to them that the public pocket is drawn upon somewhat deeply. They might then be also awakened to the fact that what they are paying for is nothing other than a meddlesome interference with private enterprise. We believe if the British public knew what costly extravagance these clauses are bound to engender, the principle of trades unionism would not receive anything like the support which is now given to it. In this respect the matter is one of general interest, and we are surprised that the leading daily papers have not devoted more attention to it. It is a gross misappropriation of public monies, calling for some action on the part of Parliament.

But from the standpoint of the employer the position is even more serious than from that of public morality. If he accepts the conditions, he is handicapped in securing the best output from his works, and is left at the mercy of his employés, for if they like to lodge a fanciful complaint an inquiry must be held by the Council as to its accuracy. In a large works this might lead to a dozen or more inquiries at one and the same time, so that the poor employer would be for ever involved in disputes which would do nobody any good, and in view of the municipal partiality for the workman might lead to the cancelling of the order after it had been three parts finished.

When so much is being written and said about masters being old fashioned or too orthodox, it ought to be borne in mind that they have been to an enormous extent hindered in their operations by the hysterical cries of a party which has been too much pandered to of late. How far the labour problem has been responsible for their slowness in adopting heterodox methods would be difficult to define to a nicety.

When the great engineering strike came to a close, conditions of management were mutually agreed upon between the Federated Engineering Employers and the Allied Trades Unions. The general principle of freedom to employers in the management of their works was approved as follows :—

The federated employers, while disavowing any intention of interfering with the proper functions of trade unions, will admit no interference with the management of their business, and reserve to themselves the right to introduce into any federated workshop, at the option of the employer concerned, any condition of labour under which any members of the trade unions here represented were working at the commencement of the dispute in any of the workshops of the federated employers; but, in the event of any trade union desiring to raise any question arising therefrom, a meeting can be arranged by application to the secretary of the Employers' Local Association to discuss the matter.

Nothing in the foregoing shall be construed as applying to the normal hours of work, or to general rises and falls of wages, or to rates of remuneration.

This clause introduced no new condition of labour. It simply provided for equality of treatment between the Unions and the Federation by reserving for all the members of all the trade unions, as well as for all the federated employers, the same liberty which many trade unionists and many employers had always had. Special provision was made in the clause and in the subsequent "Provisions for avoiding future Disputes," to secure to workmen, or their representatives, the right of bringing forward for discussion any grievance, or supposed grievance.

It is a fact, however, that some municipal authorities are attempting to go behind this decision in the clauses which they are endeavouring to get inserted into engineering contracts to-day. Let us take the case of Sheffield. The "fair contracts" clause which the Council wished to impose upon Messrs. Ferranti was as follows :—

THE ORIGINAL CLAUSE.

The contractor will be required by the contract to agree that all workmen employed in carrying out the contract in the City of Sheffield shall be paid not less than the standard rate of wages recognised by trade societies in Sheffield in each branch of trade represented in executing the contract, and to observe the recognised hours and proper conditions of labour. And for all work prepared outside the City of Sheffield and to be used in the city the minimum standard rate of wages paid by trade societies where such work is prepared, and if there be no such standard of wages in such place, then the contractor will be required to adopt and pay the Sheffield rate of wages and abide by the other conditions, as if such work had been executed in Sheffield. The contract will prescribe as the liquidated damages to be paid by the contractor, in case of breach of that condition as to wages, a sum of money equal to three times the amount by which the actual rate of wages paid by him at any period during the execution of the contract for any particular class of work is below the minimum standard rate of wages ruling in Sheffield and district for the same class of work during that period. These conditions shall also apply to sub-contractors.

THE CLAUSE AS AGREED TO.

That all workmen employed in carrying out the contract shall be paid at a rate of wages and observe the hours and conditions of labour as recognised by the Masters' Federation and the representatives of the Men's Trades Unions for the Oldham District. These conditions shall also apply to sub-contractors.

The contractors further agree that the engineer for the Corporation shall at all reasonable times during the progress of the works, have free access to the workmen of the contractors, and to the wage books of the contractors, and to the factories or other places which shall for the time being be in the occupation of the contractors for the purpose of this contract, and shall on behalf of the Corporation, be entitled to make full inquiry with the object of ascertaining that the stipulations in respect of rates of wages, and the conditions of labour, are being duly observed by the contractors.

Messrs. Ferranti objected to the clause in its original form because it was in no sense a "fair wages" clause, and because it would put the contractor working under it into an exceptional position, differing from that generally existing in the engineering trade. The firm is working its shops on

Digitized by Google

exactly the same lines as the rest of the engineers of the country as agreed upon between the Federation and the Unions as mentioned above. The firm proceeded to re-draft the clause so that it should comply with that agreement, and from the parallel columns arrangement on the previous page will be seen the difference between the suggested and the accepted terms. In one of their letters to the Council, Messrs. Ferranti wrote as follows:—

We objected to this clause, because, as a matter of fact, there is no such thing as a standard rate of wages which applies to all men of a class in any district. We fully admit that there is a standard rate of wages which applies to some of the men, that is, to the fully qualified men in their respective trades, and it is these rates which are called the standard rates of the district. At the same time, we must point out to you that it is the general custom of engineers to employ very various grades of men for doing the same classes of work, and to pay them lesser amounts in wages than the so-called standard rates, where the full amount of skill is not required for the work they are expected to do.

We have been into this matter very carefully with the Employers' Federation, and we find that we are in practice doing what is common amongst the various members of the trade, and what is, in fact, recognised by all the shops where trades unionists are daily at work.

It is to be deeply deplored that after a settlement had been arrived at in January, 1898, between the employers and the trades unions, the Sheffield Council or any other Council should use its influence to subvert that arrangement. It is quite in keeping, however, with the dishonourable and high-handed action which has characterised most of the dealings of the trade union party.

The extent to which the labour party is wrapped up in its so-called "fair" clauses is evident from a remark in a Sheffield paper:—

The electric light undertaking had far better go slow for another winter, if need be, rather than lead the Council into a reversal of its labour policy, while it tamely holds the candle for an organisation which is trying to undermine trade unionism.

It is but a short step further to say "we will place the order abroad." Of course, if this sort of thing were carried far the employés would find that they were working out their own damnation. And we wonder if in giving contracts abroad the Councils make, or would make, the least inquiry as to the conditions of workmen in foreign factories!

We note, by the way, that at Sheffield the local branch of the A.S.E. pledged itself to give its best "moral and financial" support to the labour councillors and the Trade Council in their endeavours to bring about a reversal of the committee's decision to submit to Messrs. Ferranti's terms. Presumably the A.S.E. never intended to adhere to the 1898 agreement with the Employers' Federation!

When the Council met to discuss the question, the rejection of the committee's minutes was moved in a very lengthy speech by Mr. Hobson, who referred to the breakdown of the West Ham labour clause, and quoted from the ELECTRICAL REVIEW'S comments upon that matter, and our forecast as to the determined stand which the Federation intended to make. He said that what was being done in regard to the Sheffield contract fitted in exactly with our prediction of May last. West Ham had left the fight to Sheffield; was Sheffield going to allow the employers to have their own way? And much more of this in the same vein fell from Mr. Hobson's lips. He failed to appreciate that the determination of the contractors rendered it a case of Hobson's choice! The amendment was rejected by 26 votes to 23.

By this decision Messrs. Ferranti are at liberty to apply the principle of paying wages according to merit to every branch engaged on the work, and sub-contractors may do likewise. This is nothing more than the 1898 settlement, to which we hope and believe the employers will stand firm.

The urgency with which this particular plant was required for the Sheffield electric lighting installation was, we suppose, a point in Mr. Ferranti's favour, as any delay in placing the contract would prevent the supply of the works keeping pace with the demand.

We have dwelt at some length upon this subject because, as we have said, it is one pregnant with the most serious consequences to our national industries. We trust that there will be the most solid unanimity on the part of all engineering employers, and that in due course, by gaining here a little and there a little, the true position of affairs may be better realised by the public, and the employers will reap the reasonable and just reward for their struggles. To bring this about we should rejoice to see the matter taken in hand by the writers of the leading daily journals, for it is really a national question. In that way, and with the wise local co-operation of borough engineers and electrical engineers, and electric lighting committees, the present suicidal policy of trade unionism may be effectually abolished.

REVIEW.

Journal of the Institution of Electrical Engineers. No. 141. London: E. & F. N. Spon, 125, Strand.

The general contents of this number are as follows:—Continuation of discussion on Messrs. W. Duddell and E. W. Marchant's paper on "Experiments on Alternate Current Arcs by Aid of Oscillographs." Paper by Mr. J. Elton-Young on "Capacity Measurements of Long Submarine Cables." Paper by Mr. P. V. McMahon on "Electric Locomotives in Practice, and Tractive Resistance in Tunnels, with Notes on Electric Locomotive Design."

Abstract of a paper read before the Students' Section by Mr. W. G. Royal-Dawson on "Alternating Currents of Very High Frequency." Abstract of a paper read before the Students' Section by Messrs. M. R. Gardner and R. P. Howgrave-Graham on "The Synchronising of Alternators." "Obituary Notices."

LIABILITY FOR STREET ACCIDENTS.

IN a case which was recently heard in the Court of Appeal, a question relating to the liability of a contractor for a street accident came before the Court for consideration. The excavation of the highway, which is so often a necessary part of the contractor's duty, is not infrequently attended with injury to the wayfaring public. In view of the number of foremen and sub-contractors which are often employed, questions relating to the liability of the original contractor sometimes assume considerable importance.

The laying of an electric cable or the establishment of a system of electric tramways involves the delegation of special work to the care of a sub-contractor, who selects his own workmen. What, then, is the liability of the head contractor for accidents which arise, whether by reason of the negligence of a foreman or not, in a department over which he has no direct personal control?

It will be seen that in the solution of this question we need not enter upon a discussion as to the liability of a master for accidents to his servants. Our sole object is to consider the liability of those whose actions are the cause of direct or indirect injury to the public, and whose responsibility is to be determined upon principles of common law unfettered by the existence of any contractual relationship between the parties. And this question is of no mean importance to the head contractor, for the injured party will generally seek to draw water from the deepest well by proceeding against the most substantial person.

Where work which, if properly conducted, can occasion no risk of injury to others, is placed in the hands of a builder or contractor, who selects his own workmen and servants for the performance of the work and directs the manner of doing it, it may be taken as a general rule that such contractor, and not the person who employs him, is the person responsible for injuries to strangers from the negligent execution of the work. Such is the state of the law in cases where evil consequences need not necessarily follow. But where a man orders work to be executed, lawful in itself, but from which, in the natural course of things, injurious consequences to others must be expected to arise, unless means are adopted by which such consequences may be prevented, he cannot relieve himself of his responsibility by employing someone else to do what is necessary to prevent the act he has ordered to be done from becoming wrongful.

In Black *v.* the Christchurch Finance Company, Limited, (1894) A.C. 48, which was heard in the Privy Council, the

Digitized by Google

law upon the subject was fully discussed, if not finally settled, by the members of the Court. The plaintiff there sued the defendant company for damage occasioned by fire which had arisen on their land and had spread to the plaintiff's part of the bush. It was pleaded by the defendants that the mischief had been done by their contractor. It was held that the defendant company were liable in damages for the act of their contractor in negligently and improperly lighting a fire on their land, and permitting it to spread to the plaintiff's lands; even though such contractor in so doing, disregarded special stipulations contained in such contract relative to the time at which such fire would be lit.

The same principle was laid down in Hardaker *v.* the Idle District Council (1896) 1 Q.B. 335. In that case the defendant council, being about to construct a sewer under their statutory powers, employed a contractor to construct it for them. In consequence of his negligence in carrying out the work, a gas main was broken, and the gas escaped from it into the house in which the plaintiffs (a husband and wife) resided, and an explosion took place, by which the wife was injured, and the furniture was damaged. In an action by the plaintiffs against the district council and the contractor, it was decided that the council owed a duty to the public so to construct the sewer as not to injure the gas main; that they had been guilty of a breach of this duty; that, notwithstanding they had delegated the performance of the duty to the contractor, they were responsible to the plaintiffs for the breach; and that the damages were not too remote to be recovered.

In the case which forms the subject matter of this article, the facts were as follows:—The National Telephone Company were lawfully laying down wires along the pavement in Clapham. In order to make the connections at the joints, they left the trench open at those points along the lines of piping where the joints were to be made. George Highmore, a plumber, was employed for this work, which was to be done "to the satisfaction of the foreman in charge of the work for the sum of 12s. per connection, bends included. While Highmore was doing the work he found it necessary to plunge a benzoline lamp into a ladle of molten metal. It was proved that the safety valve on the lamp was out of order. The lamp exploded and injured the plaintiff, who now brought his action against the National Telephone Company. It was proved that a servant of the company was assisting George Highmore when the accident happened. It was contended by the defendant company that Highmore was an independent contractor, and that they were not liable for his negligence, which was not part of, but collateral, to the work which he had been employed to do. It was held by the Court, which consisted of the Lord Chancellor, A. L. Smith, and Vaughan Williams, L.J.J., that the defendants were liable. The Lord Chancellor said, "In my opinion the defendants, who authorised these works to be done, whether they delegated the execution of them to another person or not, were under an obligation to protect passers-by from injury arising from the execution of their works."

It will be seen from the above decision that the liability of the National Telephone Company extends to a very wide limit. Had the accident happened owing to the negligence of someone in their own direct employ, no question would have arisen, and this case proves that they cannot delegate their responsibility to a sub-contractor.

SMOKE PREVENTION IN BERLIN.

At present Berlin has no Smoke Act, but has been considering the question, a committee having been appointed in 1892. But Paris in the meantime has drawn up smoke prevention rules, and this has stirred up Berlin, and now it is announced that after January 1st, 1900, all black smoke will be forbidden. Thus has another "verboden" been added to the already formidable list. Being legally and properly verboden, the committee thoroughly believe that there will be no more black smoke.

It will cease suddenly at 12 midnight next December 31st. Efficient devices are believed to be obtainable, and no hardships are going to be inflicted by the rule on any proprietor of a scoty chimney. During a discussion on a paper read on the subject in Berlin, it appeared, however, that smoke was not looked on by all as so great an evil. Was not London one of the healthiest of cities? We expect that the Berlin committee will be wiser and sadder men before another year has elapsed. We read of a new form of forced draught grate not much different from one described by Mr. Foley in his paper at Newcastle before the Institution of Naval Architects, which employs hollow bars perforated on the top, and fed with air by a blower. It is said that excellent results have been obtained by this bar in the way of smokeless combustion. One man deliberately states, says the *Trades Journals' Review*, that the appliance has reduced his coal cost by three-fourths. We know what this means. It may represent sound practice, but it may equally represent merely a change of fuel. We have known where a much cheaper fuel has been used by some patented apparatus, and reduced costs enormously, but after all, the cheaper fuel would have shown even better results with the original apparatus. It was by such means as this that the Hopcraft furnace was floated, great stress being laid on the reduction of one-half the fuel cost in a particular case. We happen to know the boiler, and found it was simply a case where Welsh coal had been used, whereas the cheaper fuel used by the new furnace could just as well have been used all along. The ways of patent furnace men are so wonderful, that we have become sceptical of all appliances until we have actually seen them for ourselves under a combustion rate of 18 to 20 lbs. About 12 lbs. per square foot of grate per hour seems to be a favourite rate with patent furnaces.

THEORETICAL v. PRACTICAL EFFICIENCY.

By SYDNEY F. WALKER.

The development of the electric lighting industry, and still more, that of its big brother, the use of electric currents for power purposes, renders the question of efficiency more and more important. Every fraction of 1 per cent. efficiency that the engineer can obtain in any part of his apparatus is something saved in cost. But the writer believes that in very many instances the use of the term is really misunderstood, and that engineers and committees often specify, and insist on obtaining from manufacturers, a so-called efficiency which takes from, instead of adding to, the real practical efficiency.

Let us consider first what is meant by efficiency. At once we are met by the fact, well known to the engineer who has to study the commercial side as well as the engineering side of the problem, that there are two efficiencies. Every engineering problem consists in the transformation of some form of energy, which is inconvenient for the purpose in hand, into some other form which is convenient; and the final transformation is usually only obtained after a series of intermediate transformations. One kind of efficiency, therefore, is:—The proportion of energy we obtain in the final form in which we use it, of that which is present in our initial source. In the case of the ordinary electric lighting station, for instance, we have, as our initial source of energy, the heat generated by the combustion of the coal, oil, refuse, or other combustible we use in our furnaces, or the energy present in the water, wind, or other natural source of power, that we use to move our turbines, &c. The useful energy in its final form is the sum of the energy present in the light rays furnished by the arc or incandescent lamps on the service. The efficiency of transformation is the proportion which this latter bears to the energy utilised at the source, and, as engineers know, this is very small. But there is another kind of efficiency, more important even than the efficiency of transformation, and which may be termed the commercial efficiency, viz, the proportion which the cost of the article supplied, the

Digitized by Google

electrical energy, bears to the price obtainable for it. The price obtainable for any article, even for electric lighting currents, is ruled by conditions over which usually the maker has no control whatever. When sold for lighting purposes the current has to compete with other means of illumination, and though the price obtained is in many cases higher than the cost of some of the rival illuminants, it is still ruled by how much extra the consumer can afford to pay for the increased convenience, increased safety, &c., and is still beyond the control of the supplier. The two forms of efficiency naturally work together over a large portion of the cycle of their operations; but, in the writer's opinion, there are many points at which, by an ill-judged extension of the efficiency of transformation, the commercial efficiency is lowered. One point that at once occurs to one is that of the cost of apparatus. In the commercial efficiency the interest on the capital expenditure is a most important factor. In efficiency of transformation it has no bearing at all. Now it may easily, and often does happen that in his efforts to obtain an extra 1 per cent. or 2 per cent. efficiency in any particular part of the plant, the engineer has added more to the interest on capital than he has taken off the bill for coal and other incidentals. On the other hand, by an unwise economy in certain other portions of the plant, the engineer may again be losing more on his station by current unaccounted for than he has gained in interest by the saving in cost. Again, it very frequently happens that an increase in the efficiency of tranformation is obtained by cutting everything very fine in construction, by "sailing very close to the wind," as sailors express it, with the result that very trifling extra strains, such as are unavoidable in practical work, cause a breakdown of the apparatus, a stoppage of whatever portion of the work it was performing, and a cost many times in excess of the saving due to the extra efficiency obtained.

Passing from the general question to details. If a natural source of power exists, such as water or wind, it may be economical, and therefore commercially efficient, to make use of it, notwithstanding the fact that a very large quantity of water may be used to perform the work that would be done by the combustion of a very small quantity of coal or oil. Yet, again, if, as often happens, the supply of water is uncertain, so that steam plant must be kept as a reserve, or if the cost of making reservoirs, laying pipe lines, &c., is above a certain figure, the interest may be so great as to neutralise even the full advantage of obtaining the source of energy for nothing. Again, coming to engines and boilers, the higher the pressure to which steam is raised the smaller is the proportionate quantity of coal or other combustible necessary to be consumed in the furnace, but this advantage is more than lost unless a large portion of the expansive force of the steam can be utilised. And here, again, the conditions of commercial efficiency and that of transformation do not always agree. For an ocean-going steamer there can be no possible mistake. Steam can be raised to the utmost pressure the appliances will warrant, and that can be economically utilised by means of triple and quadruple expansion engines; but the central station engineer who made use of the same engines would be most unwise, as he would add very largely to his coal bill. *En passant*, a very striking instance of the difference between real or commercial efficiency, and that of transformation, is the case of the tramp steamer. The economical speed for these ships is the low figure of 8 knots. Passing on again to the matter of engines and boilers, Welsh coal is by far the most efficient in the world, considered from the view of transformation, while town refuse is probably one of the lowest on the scale of combustibles; yet if the town refuse can be delivered and consumed, as in many cases it can, at a cost to the town less than that previously incurred in disposing of it, or even at a slightly higher cost, it evidently becomes more efficient in the commercial sense than the best coal, or other combustible which has to be paid for. The limit is reached, of course, when the extra cost of dealing with the refuse, including interest on special refuse plant, exceeds the cost of the coal for which it is substituted. Again, after the gases formed by combustion in your furnaces have done all they can in raising steam, there is still a good deal of energy remaining in them; and after the steam raised in the boiler has done all it can in driving the engines, there is still a considerable quantity of untransformed energy remaining in it. Every heat unit that can be extracted from either the gases or the steam after they have passed through their respective apparatus, is so much added to the commercial efficiency, provided that the cost of working the energy saving plant, and the interest on the capital outly, does not exceed the value of the units recovered. So, again, high speed engines which can be coupled directly to dynamos are necessarily more efficient, the combined plant, than slow speed with belt or rope driving. As they also take less floor space, their use may have an important bearing on the commercial efficiency where the land upon which the station stands is valuable, as in the centre of large towns; yet, if the use of these engines demands the presence and the time of highly skilled attendants, the commercial efficiency may possibly be lowered, rather than raised by their use. But perhaps the apparatus upon which the engineer is most tempted to proceed to extremes, in his striving after efficiency of transformation, is the dynamo and the motor. Electrical engineering is in a more advanced state, notwithstanding its so recent development, than any other branch of engineering in the sense that electrical engineers have more complete command of their work than any others. The electrical engineer who understands his work can design a dynamo or a motor for any efficiency he pleases within certain limits. It is no more trouble for him to design for 95 per cent. than for 85 per cent. His troubles commence, of course, when the cost is gone into, and it is then that he is often tempted to increase his transformation efficiency by certain measures, which in very many instances seriously affect the commercial efficiency. To take one frequent case that is often met with—transformation efficiency requires that the space occupied by air insulation and active conductors between the iron core of the armature of a dynamo or motor and the iron faces of the field poles should be as small as possible, and so the engineer is tempted to make his insulation thin radially, and the clearance between the external periphery of his armature and the polar faces very small. Sometimes Providence is kind, and the machine works all right for some time, but more frequently some trifling expansion, due to the passage of an increased current, or to some other cause, takes place, and the conductors rub on the polar face, and the machine has to stop for the time. The designer would say, of course, that the increased current, or the increased expansion from, say, another source of heat, ought not to have taken place. Experience, unfortunately, proves that it always does, or nearly always. Or if the machine escapes this fate, it will, if the insulation has been cut fine, probably fall a victim to the property the electric current has of throwing a spark across between two conductors through all kinds of intervening material when temporarily possessed of several times its normal E.M.F., as when induction takes place.

What then should be the course of the engineer who wishes his plant to be efficient commercially, as well as in the transformation sense? The answer, in the writer's opinion, is, CALCULATE! CALCULATE! CALCULATE! Calculate each item in the cycle of transformations from every point of view. Watch the loss in each transformation, and watch the cost of reducing it. One golden rule may be taken. *Nothing is so commercially efficient as continuous running.* Whether you are furnishing lights for streets, shops, &c., current for hauling tramcars, for pumping, or cutting coal, or whether you are running a cotton mill, driving a steamer across the ocean, the one thing that you can always be quite certain will pay, is continuous running; and while every possible improvement, every possible source of economy should be carefully considered and carefully tested, nothing should be adopted which admits of even the remote probability of stoppage. A striking instance in point comes from America. An electrical engineer in the States was asked to advise a man who had 100 sewing machines working as to driving them by electric motors. The question was, should one 10-H.P. motor be put in to drive the lot, 10 motors of 1-H.P. to drive groups of 10, or a motor to each machine. After the question had been explained to him, the proprietor himself decided for a motor to each machine. As he put it—if one motor of 100 goes wrong, it means one girl idle; if the one motor which drives the lot goes wrong, it means complete stoppage. In the writer's opinion, the proprietor was quite right, provided the $\frac{1}{10}$-H.P. motors were as reliable in work as the larger ones.

INDISPENSABLE ACCESSORIES OF ELECTRIC TRACTION.

By HENRY E. P. COTTRELL, A.M.I.C.E.

(*Continued from page* 305.)

Bonding.

In the early days of electric traction the earth was assumed, in accordance with telegraph practice, to be devoid of resistance, and was therefore selected to form the return circuit to the generating station. It was not long, however, before the excessive fall of pressure at the end of the line observed in working, and involving serious loss of power, was correctly attributed to the great and varying resistance possessed by the earth return. In addition to the loss of power involved, the currents which found their way back through the earth to the generating station, in seeking the path of least resistance, passed through all the metallic conduits which lay in proximity to their course, and caused most serious damage therein by setting up electrolytic action. Gaspipes, waterpipes, hydraulic mains, telephone and telegraph cable conduits were subject to most mischievous and serious deterioration, and traction companies had to make this damage good at ruinous expense. The careful investigation of the subsoil conditions led to the recognition of the following facts:—

1. That salts of ammonia, potash and soda, and carbonates of calcium and magnesium of a soluble character were always more or less present in the ground.
2. That a mere directive force in the nature of difference of pressure was sufficient to cause a current to flow.
3. That the presence of a small amount of soluble salt was sufficient to set up electrolysis, which continued as long as a current flowed.
4. That the amount of current depended upon the relative resistance of the soil and the pressure causing the current to flow.
5. That the corrosion due to electrolysis depended on the amount of current flowing from a given area and the nature of the salts present, the order of activity being chlorates, nitrates, and sulphates.
6. That there is no actual transference of iron from the anode to the cathode, this being deposited in the soil as hydroxide of iron.

From the above it was apparent that with continuous currents electrolytic action must always occur wherever a sensible difference of potential existed in the return circuit, whether that was wholly or partially composed of the earth, or so long as any of the currents found their way back to the generating station through the earth. With alternating currents the whole of these difficulties would disappear, but so long as continuous currents are used for electric traction purposes, the question of the return circuit must remain of primary importance.

Were it not for the question of cost, the difficulty involved in setting up electrolysis in surrounding metallic conduits could be met by placing them in metallic connection with the rails, so as to keep them at a uniform potential, but this would seriously interfere with the telephone and telegraph services using earth returns, by inducing heavy currents in their cables.

An ideal return circuit would evidently be an insulated copper wire of no less capacity than the feeder, with which connection could be made at every instant as freely as with the feeder, but this again is out of the question on account of the cost.

On the whole, the only reasonable alternative seems to be the utilising of the rails as the return circuit, insulating them as far as possible and improving their joint connections so that the conductivity should be uniform, or, in other words, that the joints should be abolished electrically and the drop throughout the return circuit should not exceed the restricted limits of loss due to the specific resistance of the rails. This involves the whole question of bonding and bonds, the latter being daily more and more recognised as among the most indispensable accessories of electric traction.

The specific resistance of steel rails of the ordinary composition, *i.e.*, with the high percentage of carbon now usual for railway and tramway purposes, at the ordinary atmospheric temperatures, is from 10 to 11 times as great as that of copper; but the cross section of the rails in common use for tramway purposes is from 200 to 300 times the area of the feeders, so that the conductive capacity of the rails, irrespective of the joints and insulation, as compared with the feeders, is from 20 to 30 times as great as would be theoretically necessary. It is evident that with bonds joining their ends giving approximately a conductivity equivalent to that of the rails themselves, the drop in potential due to leakage at the points of contact between rails and their supports and the rails and the earth could be reduced to a negligible amount in excess of the loss due to the specific resistance of the steel composing them. In other words, a return circuit of a uniform specific resistance equivalent to that of the rails between joints, would present such an easy channel for the return current that practically none would find its way to the generating station through earth, and the electrolytic action set up in the neighbouring pipes and mains by stray currents would be insignificant, while the drop in potential or the loss of power in the circuit through leakage, would approximate to the irreducible minimum involved in the molecular changes set up in the material of the rails, by the passage of the current. The question, therefore, of the more or less loss of power in a circuit and the production or non-production of damage to the pipes and mains existing in the neighbouring subsoil, resolves itself into the question of the effective electrical bonding of the rails.

The conductivity of a joint evidently depends upon both bonds and fishplates. That the latter, even when the rails have been in use for some time, have an appreciable effect on conductivity has been conclusively shown by Mr. H. F. Parshall in a recent paper before the Institution of Electrical Engineers. Both by laboratory tests and tests on rails in actual use with bonds and without bonds, Mr. Parshall shows that the resistance at the joint with the fishplates removed was more than double that of the combined fishplate and bond, and that the conductivity which the fishplate contributed to the joint did not sensibly deteriorate with age, the contact between rail and fishplate being preserved fairly well, even when not fully tight through the bright patches always existing on both surfaces. On the whole, the resistance at a joint increases inversely with the tightness of the fishplates and the cleanness of the contact between them and the rails, and that independently of the character of the additional bond used for the joint. Mr. Parshall expresses the resistance of the joint in terms of the equivalent rail length added to the general resistance of the return circuit by the joint,

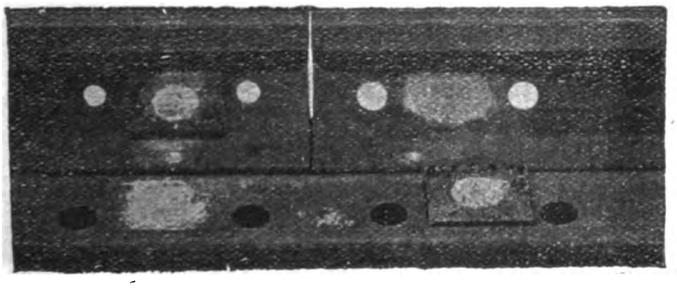

Fig. 79A.

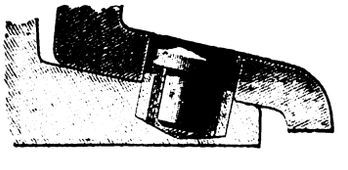

Fig. 79B.

Digitized by Google

and this seems to be a particularly happy way of expressing the matter.

There are three ways in which the ends of rails may be bonded electrically:—

1. By utilising their usual fastenings.
2. By adding bonds independent of these fastenings.
3. By dispensing with the usual fastenings and substituting a special joint or doing away with the joints altogether.

The first method involved the utilising of the ordinary fishplates with the addition of a plastic metallic composition to form a bond between them and the rails.

The only form of bond of this character which is in use is known as the Edison-Brown plastic rail bond (fig. 79A). In this bond the contact between the rail and the fishplate is established by a special metallic plastic composition inserted between the web and the fishplate, after contact spots about 2 inches in diameter have been cleared of scale and rust and treated with a solid alloy which instantly silvers the surfaces and prevents rusting. The plastic composition is held in a 1½-inch hole in an elastic cork case treated on the surface with a sticky compound, and these cases are placed in position as near the end of the rail as possible. The conductivity of the completed joint is practically equal to that of the fishplate. Some plastic bonds which have been in use for five years have shown no sensible deterioration, the explanation being that, when correctly applied, these bonds never rust.

The plastic bond is also applied (fig. 79B) in a somewhat different manner, when used for rebonding old T and girder rails, with fishplates having angle projections over the rail foot. At the end of each rail a hole is drilled diagonally through the angle plates, and into, but not through, the base of the rail. These holes may be of any suitable diameter from ⅝ inch upwards. The drill used for boring these holes is made with a specially obtuse angle, so that as it penetrates the lower surface of the plate, it carries down a burr into the surface of the rail. A part of this burr is forced between the rusted surfaces between the fishplate and the rail, and forms a telescope hole perfectly smooth on the inside. To avoid the surface being lubricated with a non-conducting substance, a solution of soda and water is used instead of oil in drilling, and the drill chips are removed with a permanent magnet. The holes are then amalgamated with the solid alloy, and partly filled with the plastic compound. An amalgamated copper plug of T shape is driven into the hole dipping into the plastic alloy, and is locked in place by a burr made with a blunt chisel. Mr. Parshall's experiments before alluded to, with 1½-inch plastic bonds and 83-lb. rails, demonstrated that the resistance of the joint expressed in inches of rail, which, with one plate only bonded, and no contact between rail and plate, except through the bonds, amounted to 24 inches of rail; by double bonding could be reduced to 14 inches, and by allowing free contact between rail and plates, to 9 inches only, the bonds being apparently responsible individually for $\frac{5}{24}$ths of the total resistance each, the contacts between fishplate and rail collectively to about the same amount as one bond, the balance being divided between the four bolts and the resistance induced by the "gathering" of the current at the bond terminals and in the neighbourhood of other points of contact between the rails and the fishplates, and amounting to about $\frac{9}{24}$ths or $\frac{3}{8}$ths of the total joint resistance. To make these plastic bonds as efficient as possible, it appears to be necessary to connect both fishplates with the rails, and to keep the fishplates in as close contact with rails as possible, or, in other words, to screw up the bolts as tightly as possible, and use some form of lock-nut that is not liable to working loose under service conditions.

The category of added bonds, independent of ordinary fastenings, comprises what might be called bonds proper, and here the ingenuity of inventors has been lavishly expended in scheming devices of infinite variety of form to meet the requirements of the case. They, however, all belong to two groups, viz:—

(A) Long and uncovered bonds;
(B) Short and covered bonds;

Group A being bonds external to the fishplates, and Group B bonds that are placed between the fishplates and the rails. These groups are each of them sub-divided into four classes according to the character of the contact established between the rails and the bonds, viz.:—*a*, mechanical contact; *b*, soldered contact; *c*, welded contact; *d*, amalgamated contact. The phenomenon termed "gathering of current," which occurs in the neighbourhood of the joints in a conducting circuit, seems to be analogous to the retardation induced in the flow of water through pipes by bends or contracted orifices, and is no doubt produced by the same causes, viz., the increased friction or resistance due to the contraction of the effective sectional area of the channel through which the flow is taking place. Successful bonding, therefore, means the limitation of "current gathering" at rail ends to the irreducible minimum involved in the flow of a current across the physical boundary or gap existing between one conductor and another. In the case of mechanical contact this gap is filled by a film of air occluded between the contiguous surfaces of rail and bond. In the case of soldered and welded contacts the gap is filled by the film of soldering or welding material, and in the case of amalgamated contact by a film of amalgam, and in all three of these latter cases by some portions of occluded air films in addition. The resistance of the gap may be further increased by the presence of a film of dirt or oxide on the surfaces. The following conditions have obviously to be observed in all bonds to ensure successful results:—

1. The sectional area of the bonds and of the rails they unite must be sensibly in the relative proportion of the conductive capacity of the metals composing them, *i.e.*, the effective areas of the channels offered to the flow of the current by rail and the bond respectively must be practically equal.

2. The contact surfaces must be as few as possible, and their areas as restricted as possible, subject to their being proportioned to the lesser conductive capacity of the two metals; *i.e.*, in the case of steel and copper, the area of the contact surface must be in proportion to the conductive capacity of the steel and not the copper, or from 10 and 11 times as great as would be necessary between copper and copper.

3. The gap between the contact surfaces must be as restricted as possible; *i.e.*, the surfaces must be brought as close together as possible.

4. The contact surfaces must be absolutely cleared of all dirt and oxides before the contacts are made, and kept clear thereafter.

If the above first condition is complied with, it is obvious that the bonds comprised in Group A must all be more costly than those comprised in Group B, which will inevitably replace them sooner or later, irrespective of the question of the relative merits of the designs.

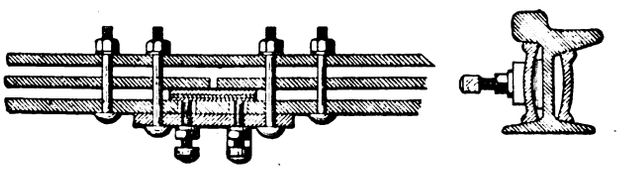

Fig. 80.—Ajax Bond.

In a similar way the constructive difficulties involved in the use of bonds composed of metals whose conductive capacity is inferior to copper must as inevitably be replaced by bonds made of the latter metal, if for no other reason than their relatively more bulky and unwieldy dimensions.

Condition 2 disqualifies all compound bonds, *i.e.*, those composed of more than one metal or of more than one piece on the score of the multiplication of contact surfaces and of the gaps between them. Condition 3 demands that the contact between the bond and the rail should be brought about by the application of considerable force in such a way that its effect shall persist, after the force is withdrawn, unaltered. Condition 4, in addition to the careful cleansing of the contact surfaces previous to bonding, also demands that they shall be treated as for Condition 3, so that the film of air imprisoned may be reduced to a minimum, and with it the chance of the future formation of a film of oxide between them similarly reduced.

This much being premised, it becomes possible to critically examine the details of the various leading bonds in use and determine their merits and defects.

Digitized by Google

Class *d*, or "amalgamated contact bonds," contains very few examples, the "Ajax bond" (fig. 80), belonging to Group B, being about the only one now used. It consists of a strip of copper placed under the fishplates and pressed against the rail ends by set screws working through the fishplates, the contact surfaces being amalgamated. The defects of this bond are:—(1) Complexity of parts and multiplication of gaps; (2) impossibility of maintaining gaps at a constant minimum interval; (3) disturbance of contacts when contraction or expansion of rails takes place, and consequent increase of resistance; (4) cost.

Class *b*, or "welded contact bonds," also contains very few known examples. The "Payne welded bond" (fig. 81) also

Fig. 81.—Payne Welded Bond.

belonging to Group B, consists of a corrugated strip of copper with flat terminals welded in any position on to the rail ends. The objections to this form of bond are:—(1) impossibility of obtaining a really perfect weld under the conditions of track-laid bonding; (2) the unavoidably increased resistance introduced by the residual film of spelter remaining between the welded surfaces; (3) increased cost involved in welding.

Of Class *c*, the only "soldered contact bond" which is at all used is the "Syracuse bond" (fig. 82). This is used

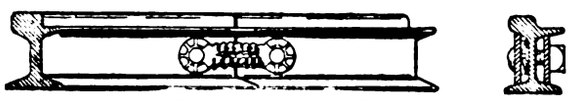

Fig. 82.—Syracuse Bond.

in forms belonging to both the long and short groups. This bond consists of broad flat terminals connected to wires by soldering, which are themselves soldered to the webs of the rails. The objections to this form of bond are due to its compound character and to the multiplicity of the gaps between its various parts; and also the relatively high cost of its application owing to the process of soldering involved.

CORRESPONDENCE.

The Glasgow Contract.

Such of your readers as are engaged in supplying local authorities with tenders for electrical or steam plant, will, I am sure, be ready to extend their sympathy to Messrs. E. P. Allis & Co. in this their hour of affliction. Although it has fallen to the lot of some of us to miss contracts at or near the bottom prices, our sorrow on these occasions has been tempered by considerations similar to those which consoled the fox when he failed to get the once coveted, but now despised, grapes. Whether our philosophy would have supported us if we had only just missed booking a top price, and such a top price as that before us, I hesitate to consider.

Permit me to suggest, for the comfort of Messrs. Allis, that, now they have come to do business in England, they must endeavour to realise that the municipal system, with all its virtues, is attended with certain inconveniences under which we all suffer. These inconveniences are known to the corporations as well as to engineers, but both are powerless to remove them.

There is not an engineer in England that has not had his brains picked and the details of his schemes published, not of malice or chicane, but of necessity, and he, recognising this fact, endeavours to possess his soul in patience.

Personally, I think Messrs. Allis made a tactical mistake in addressing their letter to the *Manchester Courier*, for Lancashire is a county of mechanics, who are just as cocksure that everything they turn out is the best that money can buy as are our American friends; and, further, they have learned by experience to render so much respect to the firm of Hick, Hargreaves & Co., and to have such confidence in all the products of Soho Foundry, that no amount of assertion would make them believe that any engine built therein could be either "inefficient, unreliable, or antiquated."

John S. Raworth.

August 30th, 1899.

THE CHARGING SYSTEM OF FIRING.

This method of firing was recently advocated in the columns of the *Practical Engineer*, and we have inquired further into the system, which we have always advocated as suited to forced draught working on the contention that fire thickness, draught, and fuel dimensions are more or less interdependent. The charging system cannot well be carried out when the rate of combustion exceeds 10 to 12 lbs. per square foot. At such rates it can be managed without difficulty, but even then some selection is required in the coal, which is best when it consists of a mixture of slack and moderately round coal. When this mixture is properly charged right along the centre of the grate, the rounder pieces tend to roll down the heap and towards the sides of the grate. The sides of the fire are thus more open than the middle, and the draught penetrates more freely, and when charging is properly done there is a belt of flame on each side of the fuel heap which curls round the furnace, and meets at the crown of the furnace. A fair natural draught of about ½ inch water gauge is necessary. As the whole heap cakes through, it is finally burned into holes, which need to be filled up, and when burned sufficiently low, the mass can be approximately levelled and recharged. With such a mass of fuel on the grate, and a reserve of draught, there is great command over the working of the boiler, and steam can be made readily. We believe that with forced draught this system has not been attempted, but we see no reason to doubt that a good stoker, who should be allowed to try the system for a time to acquire the practice necessary to a new system, would, with forced draught, secure similar results upon a heavier rate of fuel consumption. It must be clearly understood that there is no spreading of the coal upon the bars; only so much goes to the sides as rolls there by gravity, and an experienced man is able to so charge a furnace as to heap up the centre of the ridge to within a short distance of the furnace crown. It might be thought that in this system there would be a large volume of smoke produced, but this is not so. Such smoke as is produced comes off from the surface, and the whole volume of gases from the mass requires a long time to evolve, and, as it does come off, it does not come into contact with the furnace crowns, but finds itself in the narrow space between the fuel mound and the arch of flame which rises up from the sides of the grate.

In charging a fire on this system, the stoker commences against the bridge and fills up this end first, the mound sloping gradually towards the firedoor. A longitudinal section of the fire would show a line parallel some distance with the furnace crown and then sloping downwards to the dead plate in a curve, convex upwards. Similarly, a cross section would show an approximately parabolic, or haycock, form. Such a form enables the condition of the whole length of furnace to be seen from the furnace door, and is also favourable to the proper admixture of any necessary fresh or auxiliary air, the admission of which may be in smaller volume and of greater duration than when small charges of fuel are made upon a bright thin fire. In such case the hydro-carbon gases are at once liberated in great volume, and a short period of very copious air admission is necessary. As said above, with ordinary chimney draught the system cannot very well be used with a rate of combustion above 10 or 12 lbs. per square foot of grate per hour.

Mr. Ingham, a Manchester engineer of great experience in steam boiler work, rightly says, however, that with forced draught almost everything can be done, but he lays stress on

Digitized by Google

some amount of selection being necessary as regards the coal—that it should have a proportion of round coal which will roll to the sides as charged and secure the action aimed at—the flame belts round the furnace plates.

The principle underlying the method is the preservation in the furnace of a large mass of fuel ready to be quickly put into a condition of more rapid combustion as soon as a demand is made for more steam. But the method demands what is technically known as boiler room, and as we have already pointed out, where double the fire-grate area could be arranged with a given heating surface, it would appear desirable to do this or to secure the same end by means of fan-assisted draught. The tendency of late has been to claim unduly high possibilities for steam boilers. It is likely that more moderate figures will be worked to in the future.

Probably some of the excessive smoke of electric light stations is due to the too heavy work demanded from steam boilers. Where anything over 20 lbs. of coal per square foot of grate area per hour is to be consumed a fan draught will be required, and with a fan draught and bituminous coal there must be provision to bring the fan pressure to the auxiliary air ducts, for the blast pressure will prevent any fresh air being admitted at the furnace doors, and such auxiliary air must be forced into the furnace.

LONG DISTANCE TRANSMISSIONS FOR ELECTRIC RAILWAYS.*

There seems to be no doubt that in the near future long distance transmissions by means of polyphase currents will form an important feature of electric railway practice. A number of instances of this practice have already been mentioned in the *Review*, and a new road has just been projected in the Kootenay country of British Columbia which will be operated by means of a power plant which contains a number of most interesting and unique features. It should also be added that this is but one of a considerable number of polyphase transmissions in the Pacific North-west, where there has lately been remarkable activity in the projection and construction of long-distance transmissions operated by water-power. While for the purpose of supplying power for general purposes, and especially to mining machinery, the induction motor has now become a worthy rival of direct current machinery, street railways will undoubtedly continue to be operated from sub-stations containing rotary transformers for the production of 500-volt direct currents.

The West Kootenay Power and Light Company, whose plant is described in detail in the *Journal of Electricity* of May, 1899, contains an unusual number of useful and instructive features. This plant is essentially a power plant, only a small percentage of its output being applied to lighting purposes, and so various are the uses to which this power has been applied and with such eminently satisfactory results that a considerable extension of the service is to be made, including an electric railway, which is to be installed at once.

The engineering features of this plant are most interesting. The power house is situated on the Kootenay River, which forms a connecting link between Kootenay Lake and Columbia River, and the Bonnington Falls, from which the power is supplied, are situated near the lower end of this river. At low water these falls, both upper and lower, are capable of delivering 267,000 H.P., but the lower falls, a part of which the West Kootenay Company has utilised, have an available head of 40 feet at low water, and are capable of delivering 100,000 H.P.

The company constructed a canal cut out of hard rock, 650 feet in length, and 26 feet wide, the lower end of which widens out into a forebay 54 feet wide. The forebay is shut in by a dam of solid concrete, 82 feet high and 26 feet wide at the bottom, tapering to 6 feet wide on top. Across the head-race, 250 feet from the concrete dam, is a wooden dam sloping at an angle of 42°, constructed of sills and timbers securely fastened between the two high b'uffs. This dam is 44 feet high, and has five sluiceways across the bottom, the object of which is to control the supply of water to the forebay at all times.

The back of the dam really forms one side of the power house, and of the tail-race, which runs at right angles to it, being a pit 20 feet wide by 30 feet deep, and extending nearly the length of the power house, which is 66 feet. The dam is provided with two feeders of 9 feet each, and one of 10 feet, the upper ends of which are closed with wooden gates. Two outside frames extend upward of 30 feet, and the racks for raising and lowering the gates are bolted to the wall of each pit. The gates are each provided with a small iron flood-gate, and the main gates are raised and lowered by means of head-gate irons bolted to the top of the dam. The winch controlling these is operated by one man. Three steel penstocks run through the dam into the hydraulic room of the station, each penstock carrying a standpipe nearly as high as the top of the dam. To the lower end of each penstock is bolted a housing which contains a pair of 39-inch horizontal cylinder gate turbines, the housing being supported on I-beams laid on the retaining walls of the tail-race. The draft tubes 22 feet long and 10 feet in diameter are bolted to the bottom of the housings. The generators are coupled direct to the turbine shafts, and three exciters are driven by three independent 12-inch horizontal gate turbines contained in cast-iron flumes connected to the housings of the large wheels, from which they derive their water supply.

The dynamo room contains two 750-KW. generators and one of 1,500-KW., all of the standard General Electric revolving field type. These run at a speed of 180 revolutions per minute, have 40 poles and deliver three-phase currents at 1,100 volts.

The transformer room is a separate compartment at one end of the dynamo room, and contains the necessary capacity of air-blast transformers; they are 12 in number, each of a capacity of 250 KW. These deliver at a pressure of 20,100 volts to the line. The pole line is a double line extending to Rossland, a distance of 31 miles, the profile of which varies in height by over 2,200 feet, and a step-down transformer station is situated at the latter town. A branch is taken off the main line at a point three miles from Rossland which runs to Trail, B.C., a distance of four miles. At this town is situated the great smelter of the Canadian Pacific Railroad, and a transformer station at this point provides three-phase currents at 550 volts for the operation of various parts of the smelter. At this point an electric tramway is to be immediately built, the operation of the plant in all kinds of weather having been so successful as to encourage the company to extend its operation to railway work.

* *Street Railway Review.*

BUSINESS NOTICES, &c.

Bankruptcy Proceedings.—The creditors of Lawrence John Lawrence, electrical engineer, 5, Stafford Street, Old Bond Street, W., met on Thursday at the London Bankruptcy Court. The debtor commenced business about four years ago without capital. Six months later he was joined in partnership by Mr. W. H. Butcher, who introduced £200 capital, and the style of the business was altered to Lawrence & Butcher. That partnership was continued for about a year when it was dissolved by mutual consent, Mr. Butcher taking £120 in cash and the debtor retaining the stock and book debts. All the partnership liabilities were settled and the dissolution was duly gazetted. The debtor continued the business by himself up to last Christmas. In December, negotiations were entered into for the formation of the business into a limited company with a capital of £2,000, but nothing came of them, and the matter is at present the subject of litigation. Accounts filed under the failure show unsecured debts £334 8s. 7d., and assets, doubtful book debts, £50. The reasons given for the failure are bad debts, illness, loss in business, and insufficiency of capital. No offer being submitted the creditors left the matter in the hands of the Official Receiver to be wound up in the usual course of bankruptcy. The public examination is appointed for September 19th. Appended is a list of the principal creditors, viz.:—Unsecured.—General Electric Company, Limited, £81 12s. 8d.; W. McGeoch & Co., £42 8s. 11d.; Paterson & Cooper, £38 3s. 8d.; John Russell & Co., Limited, £20 2s. 3d.; H. M. Salmony & Co., Limited, £33 17s. 7d.; and various sums under £20. Partly secured.—H. J. Lawrence (security valued at £70), £100. Preferential creditor for rent, £37 10s.

A receiving order has been made in the case of H. W. Thane, electrical and general engineer, The Hill, Northfleet, Kent, on debtor's own petition. The first meeting is to be held at 115, High Street, Rochester, on September 6th, and the public examination will take place at Court House, Eastgate, Rochester, on September 4th.

Book Received.—"The Electrical Engineer's Central Station Directory." Third edition. Biggs & Son, London. 3s. 6d.

Catalogue.—The new complete catalogue just issued by Messrs. Veritys, Limited, belongs to that class of trade publications which one keeps along with directories and the other works essential in a commercial establishment, so as to be always ready to hand for reference. The catalogue being a complete collection of all the classes of electrical machinery and wares in which Messrs. Veritys do business is necessarily bulky, but it is so neat and unobtrusive in its binding, &c., that it will be quite in keeping with the most elaborately furnished offices. It is complete in nine sections, which we mention in outline: (*p*) plant and machinery; (*m*) motors and motor driving (from which we published a selection of illustrations showing motor applications some weeks ago); (*w*) wires, cables, and wiremen's sundries; (*a*) switchboards and accessories; (*b*) bells and telephones; (*s*) surgical and medical appliances; (*e*) electric light fittings; (*d*) ship, mine and dock fittings; (*g*) reflectors, glass and silk shades. In addition to a host of illustrative and descriptive matter, we notice several interesting features, viz.—Estimates for complete private plants; comparative costs of gas and electric light; hints on house wiring and joint making with wiring rules and tables; metric measurement tables; electric bell and telephone connection diagrams. The electrolier, standard and statuette fittings section has a special glazed paper which shows the illustrations up to best advantage. Some of the designs are very pleasing.

The Chitty Dynamo and Motor Company, Limited.—The senior Official Receiver, Mr. G. S. Barnes, has issued a summary of the statement of affairs on the date of the winding up (June 26th, 1899) as submitted by the directors, together with his observations thereupon. The gross liabilities are put at £32,556, expected to rank £32,342. The amount estimated as available to meet unsecured creditors (subject to cost of liquidation) is £20,912 13s. 9d., and there is thus an estimated deficiency of assets to meet the liabilities of the company, of £11,429 10s. 10d. There is no unpaid capital liable to be called up to meet the above deficiency. The capital issued is £33,030, and adding to this the deficiency above stated, there is a total deficiency of £44,459 10s. 10d. The chief cause of the failure appears to be the insufficiency of working capital. The company went to allotment on December 18th, 1897, upon a total cash subscription of £5,540. The purchase price was originally fixed at £56,000 without any valuation by Mr. Chitty and his solicitor (£11,000 cash and £45,000 in shares), but in consequence of insufficiency of cash capital, these terms were modified, and it was arranged that Mr. Chitty should be paid £28,000 (£1,500 cash and £26,500 shares), and the remaining £28,000 to be payable in proportion to a further issue of capital. Mr. Chitty was to be appointed for five years as managing director at £1,000 a year, but for the first year only £500 was paid, the deficiency to be made up in the following year by cash or shares. The expenses of carrying on the business have been £1,955 plus directors' fees, £160, salary to managing director (cash and shares) £1,530, ditto claimed to end of agreement £3,4:9, depreciation in plant, &c., £897, depreciation in letters patent £36,000. The gross receipts have been £19 15s. 9d. A dynamo motor has been supplied at £40 14s., but £10 odd has to be spent upon this before it will be in working order and payment obtained. Mr. Chitty and the other directors have valued the letters patent at £20,000, but, says the receiver, it is doubtful whether any such amount will be realised unless some scheme is formulated for working the patents. The liquidation of the company has been left in the hands of the Official Receiver with a committee of inspection.

Directory.—The "Universal Directory of Railway Officials," for 1899, has now been published from the offices of the *Railway Engineer*, 8, Catherine Street, Strand. This directory contains very useful information regarding railway officials all the world over. It is divided into sections dealing with England and Wales, Europe, Asia, Africa, Australasia, North America, South America, but there is also an alphabetical index for ready reference comprising every name included in the other sections.

Dobson & Curtis v. Weldon.—At Dublin Courts (Chancery Division) last week, this action was brought by Messrs. Dobson & Curtis, Limited, electrical engineers, Stephen's Green, Dublin, against Mr. Joseph V. Weldon, Rathgar Road, for £47 11s. 11d. for goods supplied and work done.—Defendant's counsel applied that the action be remitted to the Recorder of Dublin sitting at Kilmainham, and the Court made the order.

Electrical Progress in Germany.—From the official statistics just issued by the German Electrical Bureau in Berlin for the year March 1st, 1898, and March 1st, 1899, we learn that the increase of electrical works, &c., in the German Empire during that period has been unprecedented. For whereas in the preceding period the number was 96, it was at the end of last year 105, and it is calculated that in the current year or so the number will be increased by no less than 123 new works more. In these figures are not included installations for the working of tram and railways, or private concerns. All these works have been started since 1880, indeed, the Great Berlin Electrical Works are only 15 years old. These figures speak eloquently enough, but the figures compared with the gas statistics are still more pointed. For whereas the first gasworks in Germany were started in 1825, there are now only 816 such works, *i.e.*, in the period of 75 years the gasworks only outnumber the electrical by about 300, whilst the latter have only a history of 20 years. Indeed, it is estimated that in another four years the number of both will be equal. As regards agency of working it may be of interest to mention that three-fifths of the electrical works are driven by steam engines, and one-tenth by water turbines. The largest electrical concern in Germany is the Rheinfeld Transmission Works in Baden, capable of developing 12,000 KW., the central station in Hamburg coming next with 7,000 KW. The Berlin Electricity Works have three stations, developing respectively 1,700, 5,500, and 5,000 KW., whilst the works at Frankfort-on-the-Main produce 4,200 KW. All other works develop no less than 4,000 KW. Coming to the lighting statistics we learn that whereas in 1894 all glow lamps in Germany only numbered 500,000, they now number 2,000,000 in round figures, whilst the number of arc lamps have increased in that period from 12,500 to 41,500. The motors in working at present represent nearly 70,000 HP. As regards the future progress of electricity in Germany there is still a wide field of operation open, as although all the seven cities with a population over 350,000 have now electrical works, and all those with a population under half a million will be similarly provided at the end of the year, and only eight towns with a population below 100,000 will then still be without such, there remains nearly 3,000 towns with a population below 50,000 which possess no electrical works.

The Institution of Junior Engineers.—The summer meeting of this Institution has just taken place, the rendezvous being Portsmouth, with excursions to Southampton. There was a larger attendance than usual, being about 12 per cent. of the total membership. The party reached Portsmouth on Friday, August 11th. Among the works of interest visited was the Portsmouth Corporation Electricity Works, and it was very evident that the undertaking, under the superintendence of Mr. E. Price, was in a healthy condition. New plant was being laid down to meet the increasing demand for current. The accounts for the year ended March 31st last, showed a credit balance on revenue of £9,650. The total maximum supply demanded was 1,132 KW.; there were 261 public lamps, and the total quantity sold had been 1,224,949 units. The Southampton electricity works were also visited. The Summer Dinner was held at Portsmouth, Mr. B. H. Joy presiding.

Liquidations, Dissolutions, &c.—The Porcelain Electrical Fittings Company is to be wound up voluntarily, Mr. T. W. Hayes, Cheapside, Hanley, Staffs., being appointed liquidator.

Mr. A. Shuttleworth was in July appointed liquidator for the winding-up of Browett, Lindley & Co., Limited, now reconstructed.

Creditors of Galloways, Limited (the old company now liquidating for reconstruction), must send particulars of debts, &c., to Mr. J. W. Pollitt, 7, Pall Mall, Manchester, the liquidator, by October 7th.

Messrs. H. G. Massingham and G. N. C. Mann (Massingham and Mann, electrical engineers, Torquay) have dissolved partnership. Mr. Massingham attends to debts.

The *London Gazette* records that on August 10th a committee of inspection was appointed to act with the official receiver and liquidator of the Chitty Dynamo and Motor Company. Messrs. E. E. Barrow, A. C. Bean, and D. J. Edmonds, were appointed on the committee.

Rope v. Central London Railway.—At the Sheriff's Court on the 24th ult., Mr. Under-Sheriff Burchell and a special jury, had under consideration an action for compensation brought against defendants by Messrs. John, James, and Walter Frederick Rope, refreshment contractors, carrying on business in the Bayswater Road. The claimants, as we gather from a report in the *City Press*, had cause to make serious complaints as early as 1896, shortly after the new line was begun, about the effect of the works upon their premises and since then the damage and inconvenience had been considerable. The tunnel ran beneath the pavement, and

Digitized by Google

the oscillation caused by the work was felt continuously day and night. The property had suffered to a considerable extent, and damages were consequently sought. On behalf of the railway company several expert mining engineers were called, and expressed an emphatic opinion that the damage complained of by the claimants could not possibly have resulted from the work in operation in connection with the construction of the line. They attributed the cracks in the walls, and other damage to the age of the building, the clay surrounding the foundations, and certain recent structural alterations. The jury found that the damage had not been caused by the railway works, and gave a verdict for the defendants.

Tower Wagons.—The well-known Heathman ladders have been in use for some time at Dublin, Swansea, Prescot, and Newcastle-under-Lyme, and Messrs. Heathman & Co. are now building tower wagons for Carlisle and Sunderland. They are considered to be specially suitable for electric trolley wire construction and repair work.

Trade Announcements. — Mr. Felix Chapman, of Birmingham, has been appointed sole agent for that city and district for the British Electric Works Company's parts and fittings.

Messrs. Donnison, Burton & Co., electrical engineers of Llandudno, have opened a branch at Bangor.

Mr. Walter Gray, electrician, has just opened premises at 342, Fulham Road, S.W., as St. Mark's Metal Company.

Messrs. Sax, Slatter & Co., Limited, have removed from Foresters' Hall, Clerkenwell, E.C., to 1, Basil Street, Sloane Street, S.W.

Messrs. Laing, Wharton & Down, Limited, announce that in consequence of the rapid development of their export business, and the necessity for dealing with it in a systematic way, they have arranged with Messrs. Fry & Co., Limited, 18, Billiter Buildings, London, E.C., to attend to this department, as their special knowledge of this kind of business will enable them to deal with it to the best advantage. All correspondence relative to export business, addressed to Messrs. Fry & Co., Limited, will have prompt attention.

ELECTRIC LIGHTING NOTES.

Aberdeen.—Tenders for electrical supplies for the current year have been opened in committee and remitted to Mr. Bell, the electrical engineer, for tabulation and report.

Asylum Lighting.—The plans for the proposed electric light installation at Rainhill Asylum have been approved by the Lancashire Asylums Board. Subject to the Secretary of State's approval, £24,000 has been granted for the work.

Aycliffe.—Messrs. Cox-Walker, of Darlington, have reported to the Parish Council on the water-power available for electric lighting, and a resident, Dr. Lambert, has offered to present a dynamo to the village.

Ayr.—A letter from Mr. Hammond was before the Town Council last week in the minutes of the Lighting Committee with reference to the decision of that body to accept the proposal to exchange one of the present low speed plants for a high speed plant. Mr. Hammond asked Messrs. Siemens to quote their lowest price for the 200-kw. set and their tender was £2,880 (for a Siemens-Belliss steam alternator similar to the two recently supplied to the Ayr Corporation). Mr. Hammond asked the E.C.C. and Messrs. Fowlers to quote for a 200-kw. set, to comply with the high speed plant specification. Messrs. J. Fowler & Co. quoted £2,765 and the E.C.C. £2,575. The committee had advised the Council to settle with Messrs. Siemens on the terms quoted less £100.

Bath.—The "noisy" arc lamps led to another animated discussion at last week's meeting of the Electric Lighting Committee, a further report from Mr. Hammond as to the working of the lamps being read. It was again contended that the lamps worked without undue noise when the pressure of supply was fairly constant. Mr. Hammond recapitulated at length the steps which had been taken during the past month to place the lamps in satisfactory working order, pointing out that since the introduction of the choking coils there had been considerable improvement, the sound emitted being within the limits allowed for lamps working with alternating current. A report as to the week's test ended with the following paragraph:—"Taking the test as a whole, I am of the opinion that the carbons used by the works are quite good enough, and that the regulation of the pressure on the Brush machines should be controlled with much greater accuracy than at present." At the close of his report Mr. Hammond urged that the variation of the generating pressure was a matter over which the contractor had no control, and they could not be held responsible for any unsatisfactory results in the working of the lamps arising from the excessive variations which had been proved to take place. Under all the circumstances, he did not feel warranted in refusing any longer to grant a certificate to the contractors for the retention money, and in future he should recommend any members of the Committee who encountered unduly noisy lamps to make certain whether they were being run under proper conditions before placing the blame on the contractors or on the consulting engineer. Mr. Hammond said it also appeared, upon investigation, that it was the custom of Mr. Metzger to run the arc lamps in the small hours of the night with the Brush machines taken over from the old company, in connection with which the methods for regulating pressure were most primitive.

The chairman, Alderman Taylor, remarked that if they were compelled to believe all this report contained, it would place them in a very serious position indeed with their own engineer.

Mr. Metzger, the engineer at the works, replied in detail to the communication from Mr. Hammond. He said it was known to Mr. Hammond and the Electrical Construction Company that it was always intended to run the arc lamps off the Brush plant, but to satisfy the contractors they were run off their own machines at all tests, and at some risk to the new plant. The results always proved, in spite of what Mr. Clayden might report to the contrary, that the different machines made no difference to the humming of the lamps. Mr. Todd, Mr. Hammond's own representative, reported, as the result of special experiments on May 11th, that "a variation on the primary volts to the extent of 50 from the normal either way did not affect the noise given out by the lamps to any practical degree. As regards variation of speed, I am not of opinion that this makes any appreciable difference in the lamps beyond the fact that at the lower speed, and consequently lower periodicity, the test-room lamp seemed quieter." Mr. Hammond, writing in reference to this report of Mr. Todd, said: "For my own part, I believe the noise is due to the vibration of the working parts, and especially the core, and I cannot understand why they do not tackle the problem from this standpoint." Dealing with the report of Mr. Clayden, Mr. Metzger said it was a pity that Mr. Hammond did not observe the working of the lamps personally rather than rely altogether upon the opinions expressed by his subordinates. In his (Mr. Metzger's) opinion, the choking coils had effected a great improvement in the working of the lamps, and it only remained to be seen whether such improvement was permanent.

Mr. Shum moved a resolution to the effect that, while they could not adopt or agree with Mr. Hammond's report, they recommend the Council to pay the bill.

Mr. Shum's resolution was carried.

Mr. John then moved an additional resolution to the effect that the committee, having heard the reply of Mr. Metzger, express their entire satisfaction with their engineer's method of running the plant and general management of the station.

This was seconded by the chairman and carried unanimously.

Belfast.—The question of improving the lighting of the upper portion of North Street has been before the Police Committee, but, pending the report of the sub-committee as to the desirability of adopting electricity, action in the matter was deferred.

Brighouse.—The Council's electricity department for the year ended March 31st last, showed a loss of £205 18s. 3d. The price is to be increased from the same date 2d. per unit for lighting purposes, viz., from 5d. to 7d. per Board of Trade unit.

Bristol.—An architect is preparing plans, &c., for the further extension of the electricity works. Mr. Bell, the assistant engineer, has resigned his post, and the question of a new appointment rests with the Electrical Finance Sub-committee.

Cleethorpes.—The District Council has decided to engage Mr. A. S. Barnard as electrical expert, and the Hull Corporation is being asked to give its consent to the arrangement. The tramway company has informed the Council that plans and specifications for the power station are nearly ready.

Cobham.—The Epsom Rural District Council has been notified by the Cobham Gas Company of its intention to apply for a provisional order for electric lighting at Cobham. The Cobham Parish Council asks the Epsom body to strongly oppose the application. It is stated that the gas undertaking has been bought up by a syndicate, which intends to keep out a private electric lighting company if possible.

Coventry.—The quarterly report of the Electric Light Department, presented to the City Council on Tuesday, showed satisfactory progress. The amount of current supplied was 18,925 units, as compared with 14,178 in the corresponding quarter last year; rentals, £429 12s. 7d., as against £328 1s.; number of consumers, 147, an increase of 30.

The City Council has completed negotiations with the National Electric Free Wiring Company, for introducing its system of free house wiring.

Dover.—The Town Council will arrange for electrical illumination of the Granville Gardens and the Monument during British Association week.

Dyce.—Ratepayers were called together last week to pass a resolution forming Dyce into a special lighting district. Messrs. P. C. Middleton & Co., electrical engineers, have submitted a proposal to the Council, under which they would pay £50 per annum for spare water-power at the water works and supply electric lamps of 16 c.p. for public lighting at 25s. 6d. per annum, and for private lighting at 16s. to 25s. per light.

Epsom.—The Board of Trade has approved of the electricity supply scheme.

Fenton.—The Royal assent had been given to the Fenton Council's electric lighting order.

Godstone.—At a recent meeting of the District Council a letter was read from Edmundson's Electricity Corporation, Limited, in reference to their application for a provisional order for electric lighting in the parish of Warlingham. It was proposed to put a generating station down for the supply of both Caterham and Warlingham.

Digitized by Google

Fulham.—Messrs. Willans & Robinson, who are one of the sub-contractors under the General Electric Company, Limited, for the electrical contract for the Fulham Vestry, have offered resistance to the labour clause, which was made one of the conditions in their contract. The course matters have taken may be gathered from the following report, which we have reproduced from our exchange, the *Contract Journal*:—

"A special meeting of the Electric Lighting and Dust Destructor Committee of the Fulham Vestry has been held to consider communications from their consulting engineer, the General Electric Company, Limited, and their sub-contractors for engines, Messrs. Willans & Robinson, with regard to trade union rate of wages. The following letter was submitted from Mr. Medhurst, the engineer, who attended:—

Westminster Chambers, 13, Victoria Street, S W.,
August 14th, 1899.

W. J. H. Denselow, Esq.,

Dear Sir,—I enclose herewith copy of letter received from the General Electric Company, Limited, from which you will see that Messrs. Willans & Robinson, the sub-contractors for some of the smaller engines in your electric lighting station, refuse to be bound by the terms of the contract in respect to the payment of trades union rate of wages. You will see from the General Electric Company's letter that Messrs. Willans & Robinson have prepared a full statement of the wages, &c., that they pay their workmen, and that these they are prepared to pay for work undertaken for your Vestry. I shall be glad if you will arrange for a committee meeting at an early date for the purpose of discussing this question.

Yours faithfully,
F. H. Medhurst.

"The General Electric Company wrote as follows:—

Peel Works, Adelphi, Salford,
August 9th, 1899.

To F. H. Medhurst, Esq.

Dear Sir,—We regret to inform you that Messrs. Willans & Robinson refuse to be bound to pay the union rate of wages, and we give you below extract from their letter: "We have no reason to fear a comparison of the rates we pay with those paid by any other firm in our district, but we must decline, and always have declined, to accept union rates, or anyone else's as a standard binding upon us. Under these circumstances, unless you get the clause withdrawn, we must ask you to place the order elsewhere. We enclose list showing the rate of wages paid here, which was prepared for the information of firms tendering to the Battersea Vestry, whose order for the engines, you may remember, has been placed with us. We are willing to accept any clause which falls in reasonably with the payment of these rates. We are, of course, very sorry that this opportunity for working with you should fall through, but the acceptance of this clause would be contrary to the principles to which we have definitely decided to adhere." Will you, therefore, please instruct us if you still wish us to place the order with Messrs. Willans & Robinson, whose rate of wages (copy of which we enclose) appear to favourably compare with the rates paid in their district, or whether we are to place the order elsewhere, in accordance with the rider embodied in Clause 39 (sub-letting, &c.). We may say that we have already prepared drawing of our dynamo coupled to Willans engine, but we are delaying sending this in for your approval until we learn your decision. Unless you decide that the clause can be altered or ignored in this particular instance, we should propose to supply Musgrave engines. Your kind and immediate attention will much oblige.

Yours faithfully (for the General Electric Company, Limited),
(Signed) Tom Hawkins.

"A list of rate of wages paid was subjoined. It was decided that the Committee saw no reason why Messrs. Musgrave & Co. should not have the contract for the exciter engines. This was agreed to."

Gloucester.—The applications which have already been received for the electric light are stated to be very satisfactory, and show that the installation will result in a clear profit.

Haslingdon.—The site originally proposed for electricity works is not considered suitable, and the Sub-committee has been recommended to look for a better one.

Hornchurch.—The Cottage Homes Visiting Committee of the Shoreditch Board of Guardians have considered the question of lighting the Cottage Homes at Hornchurch by electricity, at an estimated cost of £4,000. The Guardians generally are favourable to the scheme.

Ilford.—A Local Government Board inquiry has been held here *re* the Council's proposed loan of £4,400 for a site for electricity supply and tramway works.

Kensal Town.—The Kensal Town members of the Chelsea Vestry will bring before a special Vestry meeting, arranged for September 26th, a proposal to apply for a provisional order for electrically lighting their portion of the parish.

Larne.—The District Council has passed a resolution to the effect that a committee be appointed to consider the entire question of the lighting of the urban district, with power to obtain legal advice, and to consult experts.

London, E.C.—An explosion occurred in a Bartholomew Close electric light main box on Tuesday afternoon.

Lowestoft.—The Town Council last week further discussed the question of electric trams. It was proposed that "in consequence of the decision of Her Majesty's Light Railway Commissioners with regard to the non-construction of the light railway from Gorleston to Lowestoft, the Council is now released from its engagement to support the East Anglian Light Railway Company," and that it was advisable to take a municipal electrical scheme in hand, the Drake & Gorham Company to be informed accordingly. This was not carried, as the Mayor moved and it was resolved—

That in view of the guarantee by the Drake & Gorham Electric Power and Traction Company, Limited, to proceed in the next Session of Parliament to obtain powers under the Tramways Act to construct as a tramway the portions of the proposed light railway, for which they failed to obtain the sanction of the Light Railway Commissioners, and to substitute for the proposed route of Railway No. 6, an alternative route to be agreed to by the Council, this Council will continue its support to the scheme of the said company on certain conditions.

It was stated by the clerk "that the purport of the amendment was that the Corporation would postpone their application for powers until they saw how the company fared with their application."

Middlesbrough.—The Corporation has accepted tenders for building the works for the electricity station.

Newark.—Mr. Vesey Brown has been engaged to advise the Council on an electricity supply scheme for the town.

Newcastle-on-Tyne.—The Sanitary Committee of the Corporation has decided to appoint a Committee to consider the advisability of using the city refuse for the generation of steam. It has been thought that steam thus raised might be employed for generating electricity for the Tramways Committee's purposes.

Oldham.—The Borough Council has considered and approved the minutes of the Electric Lighting Committee, referred back by the previous meeting. The committee proposed to expend about £4,000 on a boiler house at Rhodes Bank, in order to meet the increasing calls for electric light, and to prepare for the demands which will be made upon them when the local tramways are municipalised, and converted from horse and steam to electric traction.

Perth.—Tenders for the electric light installation plant have been received from over 50 firms. They were to be considered on Tuesday.

Pontypool.—The Urban District Council is to approach the Electric Light and Power Company with the view of opening negotiations for the purchase of the company's works.

St. Helens.—A Local Government Board inquiry was held on the 29th ult. *re* the Corporation's proposed loan of £3,600 for electric lighting extensions. The town clerk gave particulars of previous loans raised for electric lighting, and said that in 1897 the Corporation purchased the local tramways and resolved to build a station for generating electricity on the continuous current system, both for lighting and traction purposes. A considerable demand for motors had sprung upon the town, and the Corporation now proposed to lay new continuous current mains and relay the old alternating current cables in the districts of Parr and Sutton, two new areas to be opened. The current to the new areas would be supplied on the alternating system from the Warrington Road works. The change of current would mean that the people now using electricity would have to change their lamps, and the Corporation proposed to bear the cost of such changes, as the consumers could not be expected to bear the expense. The town clerk added that the demand for electric lighting was steadily growing. Up to March in 1897 the number of 8-c p. lights in use was 2,570; in 1898, 4,752; in 1899, and from March last to June last the number had increased to 6,714. The price for electricity up to June last was 6d. per unit, but it was now 4½d. per unit, while for power it was 3d. for three hours and 2d. afterwards. Besides the total amount of money borrowed under the Local Government Board authorities £25,000 had been obtained for tramways equipment and other purposes by permission of the Board of Trade. Mr. Highfield, the borough electrical engineer, then gave details of the scheme, and said that it would not be necessary to take up all the cables from the streets where they were already laid. They would take out only the high tension feeders. The plant for the new districts would be capable of supplying 3,500 lamps of 8 c p. The Corporation had demands for 1,200 lamps. The inquiry then terminated.

St. Paul's Cathedral Lighting.—It is stated that a contract has been given to a West-end firm for the electric lighting work at the Cathedral, and a start has been made with fitting up the necessary tubes for carrying the wires.

Shoreditch.—The proposal of the Committee to spend £4,000 on the electric lighting of the Cottage Homes will not be acted upon by the Guardians until the report has been circulated among the members.

Southampton.—The borough engineer is to prepare plans for the Works Committee of the City Council of the proposed positions of the electric light and tramway pillars on the Shirley route.

Staines.—The General Purposes and Drainage Committee has had an interview with Mr. Offor, of the Electrical Power Distribution Company, Limited, with reference to the company's proposed application for a provisional order for the district. Mr. Offor will submit terms upon which an order could be worked.

Stirling.—The Burgh Buildings, King Street, are to be lighted electrically. The master of works is to submit a specification and estimate of the cost.

Sunderland.—On Tuesday a Local Government Board inquiry was held as to the proposed loan of £40,000 applied for by the Corporation for the extension of the electric lighting station and plant. The Corporation have already spent £71,000 over electrical plant, and a profit has been realised. In view of the electric tram scheme more plant is needed.

Swansea.—It is stated that the tenders received for electric lighting plant, &c., are higher than was anticipated, and they have been referred to the engineer to report upon.

Wales.—The Urban Council of Bala has rescinded a resolution to erect gas lamps in certain parts of the town, and will re-consider the whole question of lighting, electricity having been mentioned in connection with the matter.

Walker.—Application was made at the meeting of a committee of the Newcastle Corporation last week by the Walker authorities for the erection of a power station to generate electricity. The matter will be brought up at the next meeting.

Digitized by Google

West Ham.—In connection with our account of the electricity works last week, we omitted to mention that the installation of the electric light in all the public offices, amounting to nearly 1,000 lamps, was carried out by Mr. H. J. Rogers, A.I.E.E., of Watford.

Wigan.—The Corporation has applied to the Local Government Board for sanction to borrow £90,000 for electric lighting purposes. The erection of a dynamo house and other premises will be at once proceeded with.

Woodhall Spa.—There is a good deal of talk about an electric lighting scheme which is expected to take shape directly. Our local correspondent says that an engineer has been asked to send in an approximate price for putting down a lighting plant at the sewage works and carrying current into the town by overhead wires.

Wrexham.—The Local Government Board has requested the Council to furnish certain details regarding the electric lighting work, for which it wishes to borrow £2,000.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Barcelona.—The chairman of the Barcelona Tramways Company, on Wednesday, told the shareholders that electric traction was inaugurated on their system in January last with the running of only nine electric cars. At the present time they had 78 electric cars and 42 mule cars at work, but the number of the former is being added to.

Bradford.—The City Council is to make application to the Light Railway Commissioners for an order authorising the Council to undertake to construct and work a light railway between Bradford and Leeds.

Returns showing the working of the electric tramways for the fortnight ending August 20th, show that on the Bolton section 5,467 miles were run, and the receipts amounted to £299 19s. 9d., which is equal to 13·16d. per car mile. The total receipts since April 1st, 1899, amount to £2,619 19s. 6d., or 12·49d. per car mile. On the Horton section during the past fortnight, 10,090 miles were run, and the receipts were £668 9s. 1d., which is equal to 15·89d. per car mile. The total receipts since April 1st, 1899, amount to £5,602 2s. 6d., which is equal to 14·25d. per car mile.

Dublin.—The Dublin United Tramways Company has written to the town clerk with reference to the committee's "strong conviction" that it is necessary "to provide for each car a driver or motorman, a conductor to start and stop the car, and a collector of fares." The company says that, since the opening of the electric tramways, more than two years ago, only one accident occurred, due to the falling of wires, which was attended with the slightest injury to any person, viz., the recent falling of the wires under the railway bridge in Amiens Street, where, owing to the bridge being so low, the overhead construction was of a difficult and complicated character. Since the accident occurred the committee have approved of a method of improving the construction of the overhead wires under this bridge which will prevent the possibility of such an accident occurring again. The board therefore see no necessity for employing a third man to manage the trolley rope on each of their cars, which is not required anywhere in the world where electric traction on the overhead system is in operation. It is added:—"The trolley rope is not an essential feature in this system of electric traction, and it is in contemplation to discard its use altogether, as a new type of trolley head is being introduced, which will not be liable to catch in the overhead wires."

A trolley pole broke on one of the electric cars last week, but no one was injured.

The Rathmines section of the Dublin electric tram system (between Terenure and Nelson's Pillar) was inaugurated on 28th ult.

Dundee.—The Tramway Committee last week had before it the tenders for the overhead line equipment of the Perth Road and Lochee Road routes, and these were remitted to the convener and the engineer to report as to the most advantageous tender.

Eccles.—Last week a meeting was held at Eccles of representatives from the Little Lever, Radcliffe, Barton Rural, Farnworth, Worsley, Whitefield, Urmston, and Little Hulton District Councils and the Eccles Town Council to consider a scheme for the construction of electric tramways to connect the above districts with the Salford Docks. The length of the proposed line is about 12 miles, and it will pass through districts with an estimated population of 250,000 and a rateable value of £500,000. The conference was private, but it is stated that a decision was come to to recommend the various authorities represented to agree to the construction of tramways through their districts, the trams to be electrically equipped and worked by a private company. It was decided to seek the necessary powers under the Tramways Act. The conference then adjourned for a month to enable the representatives to lay their views before their respective Councils.

Glasgow.—The Corporation Electricity Department has decided to construct a motor car for conveying members of the Committee and leading officials on their visits to the various power stations. The car will accommodate four persons and obviate the use of cabs.

Greenock.—The Police Board last week considered motions regarding the municipalisation or leasing of the tramways system, and resolved that: "If suitable terms can be arranged, the Board make immediate arrangements for leasing the whole line of tramways within the burgh as an electrical system."

Hastings.—Those who have so far successfully advocated the introduction of tramways into the borough are doing their best to educate public opinion as to the advantages of an electric tram service, by public meetings and the distribution of literature.

Italy.—The authorities of the Late Mediterranea Railways have placed a contract with the Thomson-Houston Company for the conversion of the railways between Naples and Castellammare, Rome, and Frascati, and Milan, and Gallarate into electrical lines.

Leeds.—There was a short stoppage of the electric car service on the 27th ult. through a defect in the Sheepscar feeder.

Limerick.—A private meeting of the Borough Council was held last week to consider a proposal to introduce electric trams into the city at a cost of £67,000. Messrs. Fitt, solicitor, and Fuller, C.E., attended on behalf of the promoters, and explained the scheme at length. The application was adjourned for further evidence.

Liverpool.—The Tramways Committee has decided, upon the advice of the city engineer, the city electrical engineer, and the general manager, to recommend the Council to apply for Parliamentary powers authorising them to construct various lines of electric tramway in order to complete the system for the whole city. A special Council meeting will consider the recommendation. The city engineer is to arrange with Messrs. Blackwell & Co. for the execution of the overhead work in Stanley Road between the Rotunda Theatre and the Bootle boundary at their present schedule of prices, while with regard to the other routes and extensions the engineers were authorised to obtain tenders.

The laying of the lines for the north extension to Walton of the electric tramways has been carried out so expeditiously that within a week the whole of the street works will have been completed up to Spellow Lane. It is said that early in October the line may be equipped with cars. The laying of the metals from the Rotunda Theatre to Bootle is being pushed forward, and the street works have been carried out up to Commercial Road. It is anticipated that in a fortnight's time the lines will have been laid up to the Bootle boundary, and the Aintree and Fazakerley route will next be proceeded with.

The cart owners are protesting against the rapidity with which the Corporation is pushing forward its electric tram scheme, because of its effect upon the ordinary street traffic.

London.—A correspondent of the *Daily Chronicle* advocates electric traction as a remedy for the overcrowding in London, and he urges the County Council to push forward with its scheme with all possible speed and establish a record for good and quick work. Fixed stopping places are recommended. Our contemporaries might do worse during the silly season than open their columns to a discussion showing the advantages accruing from the adoption of electricity on tramways. These benefits are matter of ancient history to the electrical engineer, but the average Londoner knows little thereof, and he would be more enlightened by such a correspondence than by the trashy rubbish on impossible subjects which has been appearing of late.

Mirfield.—The District Council has resolved to invite the Huddersfield Corporation to extend the proposed electric trams to Mirfield.

Mumbles.—The British Electric Traction Company have, it is announced, just taken possession of the Mumbles Railway and Pier.

Newcastle.—The city engineer has submitted his observations upon the recommendations of Prof. Kennedy and Mr. Hopkinson *re* electric tramways. They are as follows, says the *Newcastle Leader*:—

Both of these gentlemen (Prof. Kennedy and Mr. Hopkinson) agreed that the use of conduit and overhead together is quite practicable; but neither of them is enthusiastic in advising its adoption, and both of them seem to me to have rather a leaning towards the surface contact system, which they both consider to promise well in the future. Kennedy puts the cost of the surface contact system at about the same as trolley; Hopkinson does not give any estimate.

Hopkinson does not advise the combination of the trolley and conduit, and suggests the installing of the trolley throughout, but regarding it as only temporary in the central streets where it may be replaced in future by the perfected surface contact system. I accept Kennedy and Hopkinson as authorities, and adopt their electrical conclusions as accurate. Mr. Hopkinson's proposal to instal the overhead trolley temporarily in the central streets seems to me, however, a doubtful policy. I was inclined at first to agree with it, but on second thoughts it does not settle anything, and leaves the old difficulty untouched. If, on the other hand, the surface contact (or the conduit system) is installed at once in the central streets, it settles the disputed matters once and for all. There may be some future expense in following up the improvement of the system, but, if the experts are right, it will only be in matters of detail that changes will have to be made.

Considering all things then, I am of opinion that the least risky plan will be to put down the surface contact system at once in the central streets at least, to be worked in conjunction with the trolley outside, and to discard the conduit, which is apparently not favoured by the experts, though Kennedy's report to the London County Council is much more favourable to it.

The City Engineer will probably live to rescind his present decision. The New Tramways Committee, it will be remembered, recommends the adoption of the trolley for the centre of the city, and the matter comes before the Council on September 6th.

Digitized by Google

Rothesay.—The Council has considered the agreement between a committee and the British Electric Traction Company, who propose to purchase the present tramways and run them electrically. There were two clauses submitted. The Council generally adopted the proposal, but one clause was altered so that granite setts will be laid between the rails, and for 18 inches on each side of the rails, the remaining part to be tar macadam.

Sheffield.—On Friday last week Sir Francis Marindin, chief inspector of the railway department of the Board of Trade, inspected the track of the new electric tramways, with satisfactory results.

On Tuesday, Mr. A. P. Trotter, electrical adviser to the Board of Trade, inspected the new electric tramway power station.

South Shields.—Public meetings are being held here to stir up a movement in favour of municipal electric trams.

Walsall.—It is feared, says a local correspondent, that the notice which has been, or is to be given by the Town Council to the South Staffordshire Tramways Company of their intention, six months hence, to determine the agreement dated February 11th, 1892, as to the use of electricity on the lines, and also of the intention of the Council to purchase so much of the tramways as was authorised by the Walsall and District Tramway Order, 1882, may lead to some inconvenience by dislocation of the traffic.

Southampton.—A deputation recently waited upon the secretary to the Board of Trade (Sir Courtenay Boyle) relative to the proposed reconstruction of the permanent way and to the necessity of obtaining increased borrowing powers for the tramways undertaking. The Council last week resolved that, having regard to the satisfactory interview with Sir C. Boyle, "The Tramways Committee do exercise the power given them by the Council on July 26th, 1899, to accept tenders for the reconstruction of the tramways between Portswood Terminus and the Docks, and that it be an instruction to the Finance Committee to provide for the payments from time to time to be made to the contractors in respect of these works from a Special Suspense Account to be created upon the best terms that the Committee may be able to obtain." The provisional order, it seemed from the discussion, was not obtained when it ought to have been, but it was considered that it would not prejudice the Council in the eyes of the Board of Trade when applying for the order if they did not delay the works.

TELEGRAPH AND TELEPHONE NOTES.

A Cape-Australia Cable.—In the following extract from an Australian paper it will be seen that the Eastern group of cable companies do not yet despair of maintaining their hold on telegraph traffic from Australia. They have, it is true, abandoned the absurd claims they advanced for subsidies, guarantees, and a monopoly of the right to land cables at all the numerous places where their existing cables already land. They also volunteer a reduction on the present charge for telegrams to Australia (a reduction which may cause a delay in the reform of the rates to India). The return they ask for this self-effacement is apparently insignificant, but we hope that the experience which the Colonies have had in the past of the dealings with these companies will not fail to show them that the closest scrutiny should be made, and the greatest publicity possible should be given to the terms of the "privilege" asked for. We should not be in the least surprised to find that the nature of this "privilege" will be such as to amount, indirectly or directly, to a joint-purse agreement with the Colonies of West and South Australia at least, as these Colonies are the proprietors of the trunk landlines, the "harassing and annoying delays" on which have driven their old allies, the submarine cable companies, to project the laying of a cable, which will be in direct competition with these inefficient Government landlines, unless some agreement is come to between the companies and the Governments. The extract is as follows:—"The Eastern Extension Company has forwarded to its representative here, by cable, the following outline of a new scheme for an alternative cable *vid* the Cape:—'As public opinion in Victoria apparently favours an alternative cable *vid* the Cape, rather than by the Pacific route, and according to the Chancellor of the Exchequer's admission, the company's Cape proposal was also preferred by the Imperial Government, but fell through because Australia refused to assist it, we are willing to meet the difficulty by making the following liberal concessions, namely: We will entirely waive the renewal of subsidy and guarantee against competition, and, in addition, to providing a cable from the Cape all the way to Glenelg, *vid* Perth, will agree to at once reduce the tariff to 4s. per word, and make further reductions on a sliding scale as the traffic increases. In return for the above the company would only require the same privilege in the Colonies as they have hitherto enjoyed in Great Britain, of directly delivering and collecting national telegrams to and from the public. The length of proposed line would be about 7,700 knots, including connections, thus: Natal to Mauritius, 1,818 knots; Mauritius to Rodrigues Island, 406 knots; Rodrigues Island to Cocos Island, 2,218 knots; and Cocos Island to Perth, 1,862 knots. From Perth the cable would be submarine to Glenelg, South Australia, which would remove the harassing and annoying delays which are experienced with the landlines.' The cost of the line is estimated at £1,500,000. Sir George Turner, when seen in reference to the proposal, said he could not state his views until he had consulted the Postmaster-General; and it was quite possible the matter would have to be referred to a conference of the Australian Premiers."

Glasgow Corporation and the Telephone Service.—The Corporation had another debate last week with reference to the rights of the Postmaster-General to open the public streets and give the National Telephone Company a right of way. There were also some hard things said about the anomalous state of affairs caused by the Government Telephone Act. The Statute Labour Committee's report was before the meeting, and it was stated with reference to the recent decision of the Railway Commissioners against the Corporation in their refusing to allow the Post Office authorities to open the streets for post office purposes, that the sub-committee had had a meeting, and had resolved to appeal against that decision to the Inner House of the Court of Session. The committee had taken the opinion of counsel. It would cost a little money, but after they had gone so far, the committee felt bound, on behalf of the Corporations generally throughout the country, to fight the issue to the bitter end. This course was agreed to.

The Pacific Cable.—A Reuter dispatch from Wellington (August 29th) says that the New Zealand House of Representatives, in committee, has adopted resolutions authorising the Government to contribute towards the cost of the construction and maintenance of the proposed Pacific cable.

Wireless Telegraphy.—A New York telegram from Laffan's Agency to the *Times* says:—"Encouraging experiments in wireless telegraphy, in which kites were used, have been made between Harvard College and Milton, Massachusetts. The distance was 12 miles, and there were considerable difficulties, owing to the electric power houses, electric trolleys, &c., on the route. In spite of this, however, it was possible to telegraph at the rate of 10 words a minute, and it is thought that greater success will be achieved when the disturbing elements have been overcome. The process employed was practically the same as Signor Marconi's, but wires hanging from the kites were substituted for poles. It is claimed that these have an advantage over poles, as being more easily adapted for any height or distance."

CONTRACTS OPEN AND CLOSED.

OPEN.

Barking Town.—October 24th. The District Council wants tenders for boilers, pipe work, two 100-kw. steam dynamos switchboard, motor and trailer cars, trucks and electrical equipment overhead equipment, underground feeders, conduits, road work, &c. for the Barking and Beckton light railways. See "Official Notices" this week.

Barnsley.—September 16th. Tenders are wanted for electric light wiring and fittings at the Harvey Institute, Eldon Street, for about 700 lights. See "Official Notices" August 18th.

Barnsley.—Tenders are to be invited for wiring the Public Hall for electric lighting.

Belfast.—September 31st. The Electric Committee wants tenders for c.i. floor plates and w.i. rails for the electric light department. Specifications from the city electrical engineer on payment of one guinea, returnable as usual.

Digitized by Google

Bermondsey.—September 13th. The Vestry wants tenders for electric lighting work at the Town Hall. See "Official Notices" this week.

Carlisle.—September 11th. The Corporation wants tenders for extension to steam, drain, and feed pipes, feed pump, and extension of economiser at the electricity works. See "Official Notices" August 18th.

Carlisle.—September 18th. The Corporation wants tenders for extension of switchboard for dynamos 5 and 6, and for traction work. See "Official Notices" this week.

East Ham.—September 9th. The Urban District Council wants tenders for combined electric light and traction plant, engines, generators, overhead line equipment, cars, switchboard, arc lamps, &c., water-tube boilers, condensers, and other steam plant, electric light cable. Mr. W. C. Ullmann, The Limes, White Post Lane, East Ham, is the Council's electrical engineer. See "Official Notices" August 4th.

Germany.—September 20th. Tenders are being invited until September 20th by the Cotton Wool Exchange authorities in Bremen for a complete installation of electric lighting in the new Exchange. Tenders are to be sent to Das Banbureau für die Bremer Baumvoll börse la Dechanatstrasse, Bremen, whence particulars may be obtained.

Hackney.—September 12th. The Vestry wants tenders for four sets of direct current steam dynamos (either high or low speed). See "Official Notices" August 11th.

Heckmondwike.—September 20th. The District Council wants tenders for the supply of water-tube boilers, economiser, pipe work, steam dynamos and motor boosters, accumulators, switchboard work, travelling crane, mains, arc lamps and posts, and station lighting. See "Official Notices" August 25th.

Ilfracombe.—September 25th. The District Council wants tenders for boiler plant, engine plant, dynamos, condensers, switchboard, mains, lamp-posts, accumulators, meters, crane, buildings, &c. See "Official Notices" August 18th.

Luton.—September 22nd. The Council wants tenders for boilers, superheaters, engines, dynamos, switchboard, steam and other piping, batteries, street conduits, boxes, feeders, arc lamps and posts, and various other plant and machinery for the electric lighting installation. See "Official Notices" August 25th.

Malmo.—September 1st. The Gas Works' directors want tenders for the erection of electricity works for the city. Particulars on application to the clerk of the Gas Works (deposit 12s).

Middleton.—September 20th. The Corporation wants tenders for Lancashire boilers, superheaters, economisers, steam pumps, condensers, steam dynamos, balancer and boosters, switchboard, accumulators, cables, crane, &c., for electricity works. See "Official Notices" this week.

Moscow.—*Commercial Intelligence* says that electrical engineers and contractors will shortly be invited to compete for the electric railway for Moscow. The contract will probably require an expenditure of about 20,000,000 roubles.

Oldham.—The Electric Light Committee invites tenders for rolled steel girders, concreting, and other works required in the foundations for "Kleins Tower Water Cooler" at the electric light station, Gas Street, Oldham.

Poplar.—September 6th. The Guardians want tenders for high speed engine and dynamo, electric motors, Lancashire boilers, economiser, and other plant, as briefly particularised in our "Official Notices" August 18th. Mr. Warden-Stevens, the consulting engineer, asks us to notify that Section L., Steam Jet Plant, relates to ejector condensers, jet pumps, and injectors; and Section M., Auxiliary Pumping Plant, to air compressors, centrifugal pumps, and three-throw pumps.

Portugal.—September 6th. Tenders are being invited by the municipal authorities of Cascaes, Portugal, for the concession for the electric lighting of the town.

St. Annes-on-the-Sea.—September 11th. The Council wants tenders for high speed engines, continuous current dynamos, and balancing booster, for electric lighting. See "Official Notices" August 18th.

Salford.—September 12th. The Tramways Committee is inviting tenders for 100 tramcars. See "Official Notices" this week.

Sunderland.—The Corporation wants tenders for four 270-kw. three-crank direct current steam dynamos, and two surface condensers and cooling tower. See "Official Notices" August 18th.

Sydney (N.S.W.).—November 3rd. The Municipal Council of Sydney is inviting tenders for the construction and erection of a refuse destructor for treating 60 tons of refuse per day (24 hours).

Tiflis.—The Town Council is inviting tenders for a tramways concession, one of the conditions being that the present horse traction shall be replaced by electric traction, the new lines to be also worked by electric power. The Managing Department of the Town Council, Tiflis, Transcaucasus, is open to receive offers until the beginning of October.

CLOSED.

Blackpool.—The Electric Lighting and Tramways Committee have decided to recommend the Council to accept the tender of the British Thomson-Houston Company, Limited, for the 10 car equipments, for which tenders were recently asked.

Cape Town.—Both electric light and electric traction are making headway at Cape Town. At the last meeting of the Municipal Council of the city tenders were under consideration for machinery for the extension of the Dorp Street generating station. The tenders recommended for acceptance were those of Messrs. Sissons & Co. for the supply of two engines, each of 500 I.H.P., for £2,200; Messrs. Clayton & Shuttleworth, four boilers of the locomotive multitubular type for the sum of £2,390; Messrs. Bailey & Co., a pump, £225; and the South African General Electricity Company two dynamos, each capable of an output of 350 kw. as a continuous load, £3,150. It seemed, however, that the South African General Electricity Company had requested a definite reply to their offer in a fixed time, and as the Council could not give this the tender was withdrawn. The Public Works Committee were empowered to accept the next lowest tender. With regard to the electrical tramways, formal consent was given to an extension by the Metropolitan Tramway Company of the lines to Tamboer's Kloof.

Halifax.—The contract for electric lighting work at the Municipal Technical School has been given to Messrs. Laing, Wharton and Down at £405. There were altogether 16 tenders ranging from £361 to £628.

Ingleton.—Ingleton Electric Light Company have let the contracts for the construction of a weir, pipe track, launder and turbine house works, and the electrical machinery contracts are to be let in a few days.

NOTES.

The Glasgow Corporation Contract.—We were credibly informed that the Allis Company tendered for the alternative two-crank engine for the Glasgow tramways, and before our article on page 343 went to press we inquired telephonically at Mr. Blackwell's office whether this was correct. Unfortunately he was away in Glasgow, the gentleman who looks after the Allis engine matters was out, and nobody in the office could give us one word of information. Since we went to press a telegram from the North informs us that the American makers tendered for the three-crank. That portion of the article, therefore, alluding to what we understood to be the American tender need not be seriously considered, nor our remarks on Mr. Parshall's apparent requirements, which are now shown to be unwarranted.

On Monday the Tramway Committee met the representatives of the four offerers, to each of whom eight questions were put. The matter was afterwards discussed for some hours. Bailie Thomson moved that the contract for the four main engines be given to Messrs. John Musgrave & Sons, Limited, Bolton, on condition that they be completed within a stipulated time. Their estimate is £95,516.—Bailie Steele moved that the contract for two of the engines be given to that firm and two to the Edward P. Allis Company, the American firm, whose tender to construct the four engines for £114,000 was originally accepted by the committee. On a division Bailie Thomson's motion was carried, but as Mr. Musgrave could not agree to the stipulation laid down, the meeting adjourned without coming to any definite conclusion. Another meeting of the Tramway Committee was called for the following afternoon to reconsider the matter.

Personal.—Mr. A. F. Malyon Eatrill has resigned his position as engineer-in-charge at West Ham electricity works, he having obtained an appointment with the Electrical Power Distribution Company.

(*Continued on page* 366.)

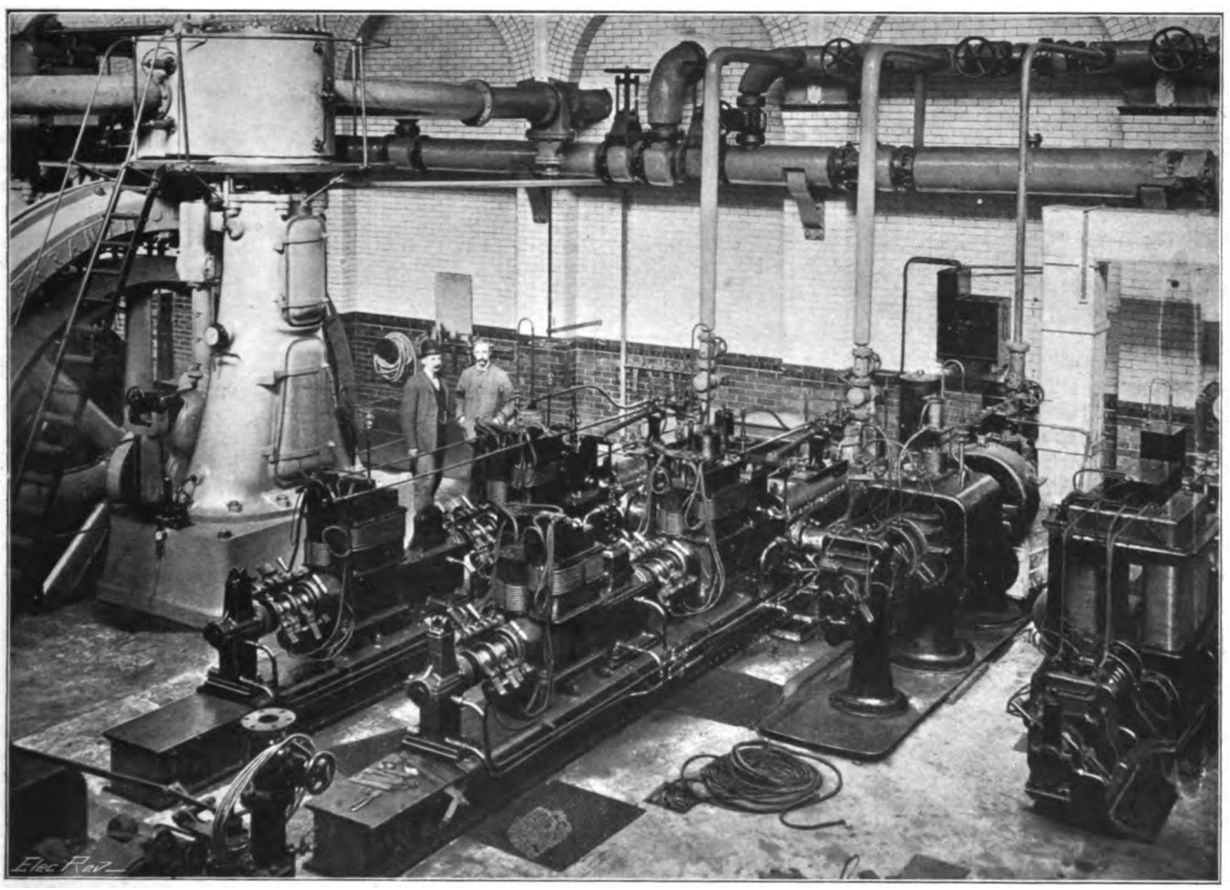
THE CONVERSION OF BLACKPOOL TRAMWAYS.

It is not without a feeling of regret that we write the above words. The Blackpool Conduit Tramway was one of our venerated standards of reference; being one of the earliest attempts at carrying out a system of electrical tramway traction on a practical scale, and certainly the very first successful conduit system, it constituted the outward visible sign of our country's claim to be considered as pioneers of electric traction.

The line was constructed to the designs and under the supervision of Mr. Holroyd Smith, who merits all honour for his courage and originality. It was opened in 1884, has run ever since, and might still have been in operation had it not been for the adverse conditions under which it laboured. What modern engineer would so much as attempt to build and work a conduit which was exposed to sand-drifts and to flooding with sea water? Small wonder that a time came when it was seen to be imperatively necessary to reconstruct the line, and place the conductors out of harm's way. We cannot but agree as to the wisdom of this course, however much we regret the necessity.

It should not be forgotten that in spite of, or, rather, as the result of, the many attempts which have been made of recent years to evolve a perfect conduit, the general form and equipment of the Holroyd Smith conduit have been retained by the best designers, even to the porcelain insulator and the cotter to grip the conductor—modified in construction, no doubt, but in essence the same. The earth return, however, has been avoided by the use of conductors of opposite polarity in the conduit.

The original tramway was laid down by the Corporation and leased for seven years to a company; the Corporation then—in 1892—purchased the plant, &c., for the sum of £15,587 inclusive. Part of the conduit was relaid, and further expenditure of the same kind incurred in 1893-4, but on account of the frequent failures and unsatisfactory working, the whole of the conduit along the Promenade was relaid on a new principle in the winters of 1894—6, at a cost of over £8,000. Still the trouble increased, and after a report from Mr. Quin, who took charge in 1897, a deputation from the Council visited various places on the Continent to examine the systems in use. Their conclusions, which were embodied in a report issued in March, 1898, and were strongly in favour of an overhead system, were adopted by the Council.



Turbo-Generators in the Electricity Works.

The system now in operation employs the overhead wire and side trolley, with the usual rail return. It is remarkable on the score of the short length of the bracket arms, and the great length of the trolley poles; these peculiarities were due to the desire of the Corporation to avoid disfigurement of the promenade along the sea-front, which is traversed by the cars, and the justice of their choice is evidenced by the artistic and inoffensive nature of the construction seen in the accompanying photograph of the promenade. By this means the local opposition to overhead construction was overcome, thanks to the untiring efforts of Mr. Quin, the Corporation electrical engineer, to solve the problem.

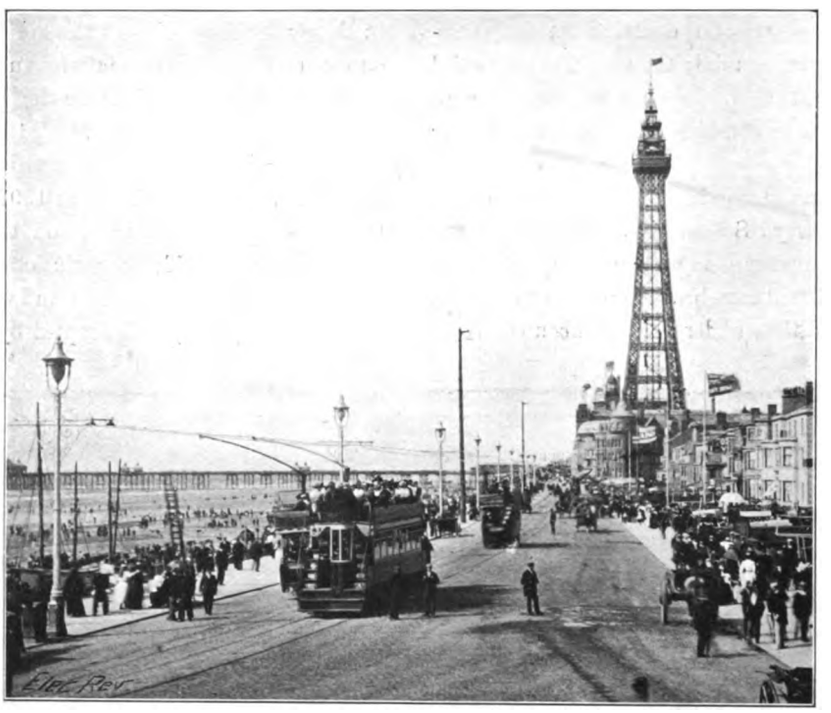
The motive power is derived from the municipal electricity works, the lighting and traction having been combined since

Digitized by Google

1894; there are two Parsons turbo-generators in the station, of 400 H.P. altogether, which are seen in our view of the engine room. The turbines are compound, and are coupled to generators of the two-pole Parsons type, running at 250 volts, each engine driving two dynamos coupled to the same shaft and joined in series.

The whole of the feeders were made and laid by the British Insulated Wire Company, Limited. There are three feeders of 0·3 square inch cross section, running from the works to the first feeder pillar on each section of the line, and 0·2 square inch from there to the next pillar. Each feeder pillar serves ¼ mile of double wire on each side, and is fitted with four of Mr. Quin's patent maximum and minimum automatic cut-outs, of which we give an illustration.

The cut-outs are provided with a shunt and series coil in opposition, the shunt coil being excited by current brought through a pilot wire from the end of the section, so that if by any chance the trolley wire should be broken, the magnetising current is cut off from the shunt coil, and the switch released, so that current is cut off from the fractured wire before it has time to reach the ground. Should a short circuit come on the line, the current through the series coil causes the pull of the shunt coil to be neutralised, and in this way also the switch is released. These switches have now been in use at Blackpool some time, and have never failed to protect the line when called upon to act.



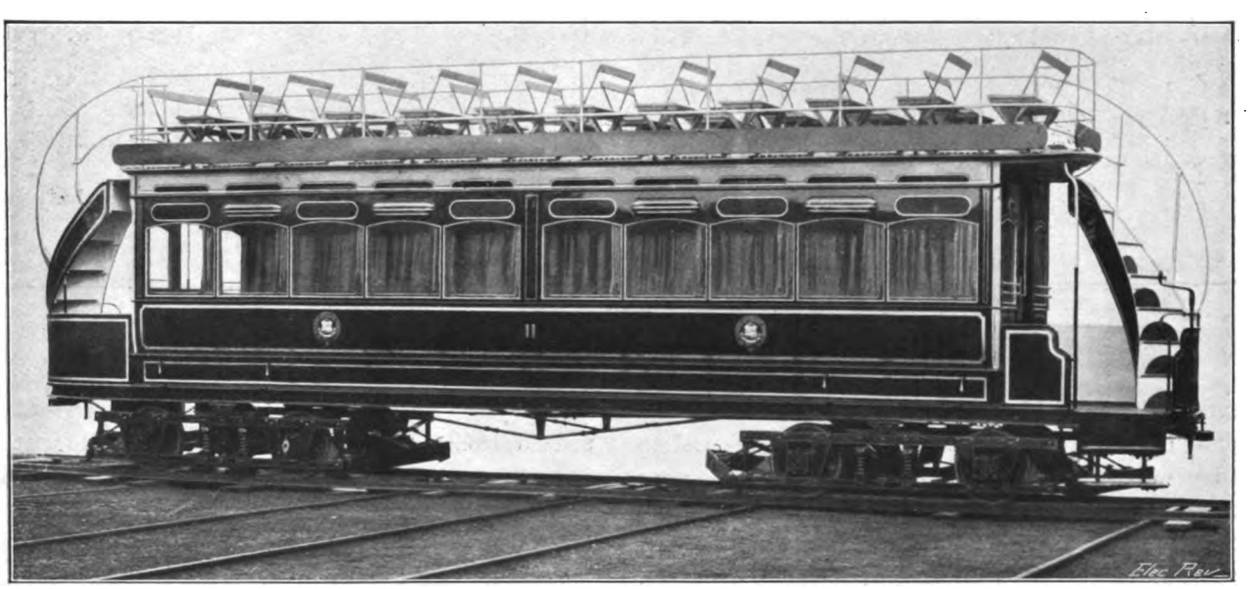
Promenade, looking Northwards.

The special cast-steel points and crossings and the spring points were supplied by Messrs. Askham Bros. & Wilson, Limited, who also supplied the material for the original conduit and for those laid down by the Corporation.

The contract for the poles and overhead line equipment was let to Messrs. Lowdon Bros. & Co., of Dundee, Edinburgh, and Glasgow, who commenced the work in December of last year. The poles, of which there are 152, are of mild steel and butt welded. They are each in one length of 28 feet. The pole at the foot is 8 inches outside diameter, and is half parallel and half taper, tapering from 8 inches to 5 inches at the point; the metal is of a uniform thickness of $\frac{7}{16}$ inch.

Before erection the pole is slipped through a plinth, which is of cast-iron, with ornamentations, and the Blackpool coat-of-arms, and was designed by Messrs. MacFarlane, of Glasgow. The pole is stepped into a cast-iron plate, with a socket and set screws, at a depth of 5 feet 6 inches from the surface.

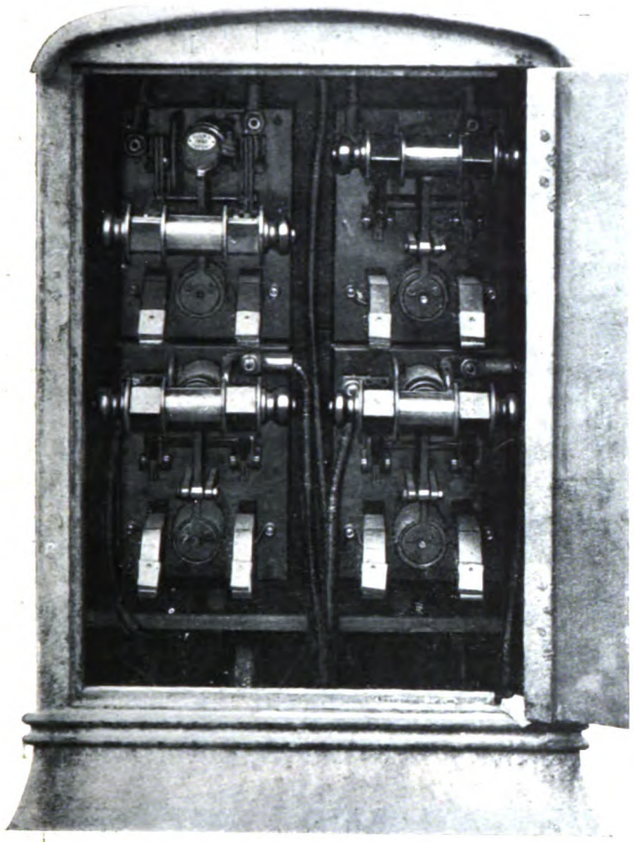
The cross arms are Mannesman steel tubes 2 inches outside diameter and ½ inch thick. Instead of being screwed into clamps and bolted round the pole, the cross arm is slipped through a hole in the pole, which makes a much neater and stronger arrangement than the clamps. The cross arms are supported by wrought-iron ornamental scroll work. For about two-thirds of the route the poles are on the pavement at distances varying from about 9 to 18 feet from the track.



Bogie Car.

Digitized by Google

The remainder of the route is on the centre pole system. The maximum span is 40 yards. The trolley wire is



Feeder Pillar with "Quin" Automatic Cut-outs.

000 gauge, and on testing was found to have a tensile strength of 28 tons per square inch.

The clamps and insulators are the standard West End pattern, and the line is doubly insulated, having, in addition to the usual insulation, a rubber sleeve slipped on to the cross arm, over which the hanger is clamped.

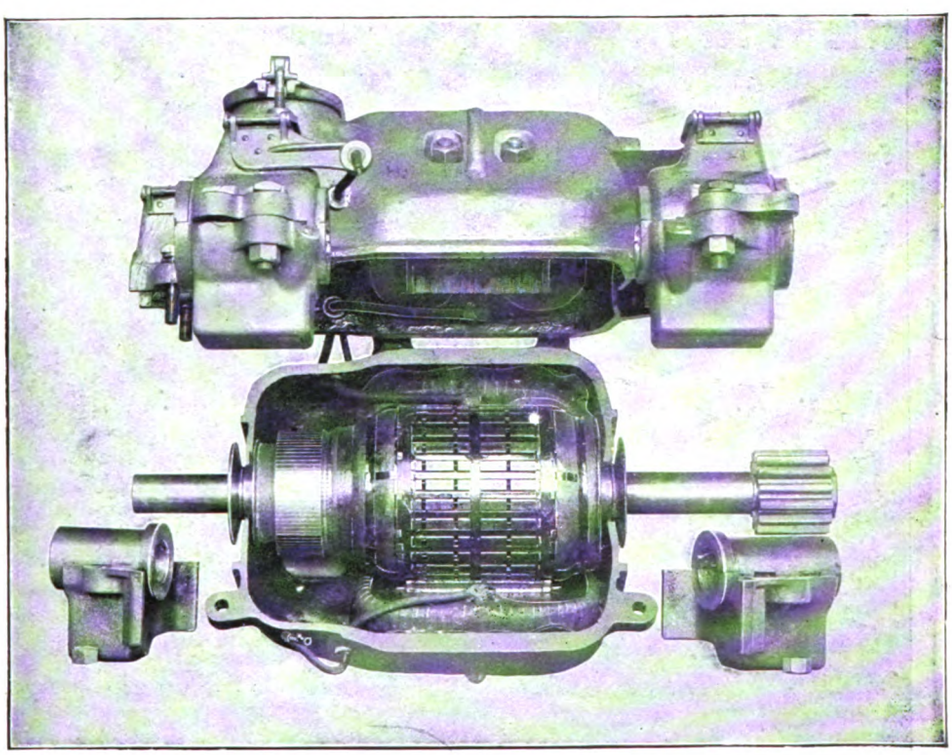
A unique feature of the system is the extremely long trolley arm, which is 20 feet in length from the trolley wheel to the standard. The trolley arm is a single steel tube, tapering from 2 inches diameter at the butt to $1\frac{1}{8}$ inches at the point. The trolleys are "Little and Ireland's" patent, with internal concentric springs, so fitted as to give an equal pressure on the trolley head when the trolley arm is moved through a vertical angle of about 20°. Of course such a long trolley arm necessitates an exceptionally powerful set of springs in the trolley standard. The springs, of which there are two pairs, are spiral, and are concealed inside the standard. They are wound to form two double sets, the smaller set being slipped into the core of the larger. These actuate a copper plunger, making contact with a hard copper spring, which again is connected to the controller. Thus the whole trolley arm is perfectly free to swivel, and the tension on the springs may be adjusted by means of a screw attached to the plunger. At some parts of the route the trolley has to swing from behind the car, right out to an angle of 45°. Owing to this it was found necessary to design a special trolley head, which would be durable and would also swivel easily. The new form of head is mounted with ball bearings, both on the turntable and the trolley wheel. The trolley wheel is a light steel casting with a gun-metal liner, a brush being used to conduct the current from the wheel to the trolley lead. The insulation of the trolley arm is also of special design. A thin steel tube is used as a former, and is coated inside and out with mica. This tube is inserted between the trolley head and the trolley arm, and forms a strong and efficient insulation.

The cars are of various ages and various types, some being 14 years old, others about two years old. Six cars have double trucks, four have single trucks, and six have no trucks at all, the car body being carried on axle brackets, as in the old horse cars; on all these cars are trolleys having 20-feet arms.

We illustrate on the previous page one of the bogie cars supplied to the Blackpool Corporation by the Lancaster Railway Carriage and Wagon Company, Limited, before the overhead system was adopted.

The trucks are equipped with G.E.-52 motors, and K.-10 series-parallel controllers with emergency brakes are used, all supplied by the British Thomson-Houston Company, Limited.

The two latest cars which Messrs. Milnes & Co., Limited, supplied to the Corporation are especially interesting, in that they have the largest carrying capacity of any electric tramcars at present running in England, viz., 36 inside and 50 on the roof, making a total of 86 passengers. The inside seats are longitudinal, of pitch pine and sequoia wood slats, supported on turned ash legs, and the roof seats are of the garden type, with reversible backs; they are also provided with Challenger's rainproof fittings. Another interesting feature in connection with these cars is the special design of the platforms; the latter are provided with double staircases and the steps are suspended the full width of car to facilitate loading and unloading, by which means the enormous crowds of passengers are dealt with with the shortest possible delay. The centre part of the platform is framed up on one side, with glass in the upper part to form a protection for the driver.



G.E.-52 Motor with Lower Frame Dropped.

The car body is mounted upon two bogie trucks of the double bar frame type, of Messrs. Milnes' design and manufacture. The car body rests on rollers, and there are vertical rollers mounted on cast-iron sliding pedestals, resting on compound $\frac{3}{4}$ inch steel spiral springs, with bottom cups and blocks

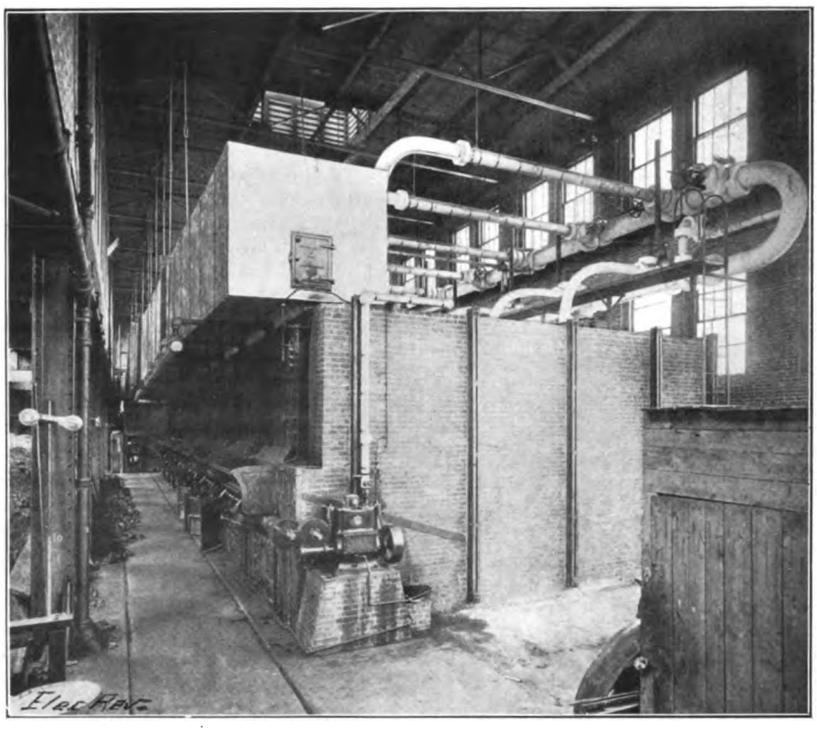
Digitized by Google

secured to the bottom framing of the truck, arranged so as to take the end and side thrust of the car; the truck is also fitted with centre radial pivots and side plates to ensure easy riding. The wheels are of chilled cast-iron. The trucks are fitted with patent roller bearing axle boxes.

The general dimensions of the car are as follows:—Length outside body, 26 feet; extreme length over platform steps, 37 feet 10 inches; extreme width, 7 feet; height inside at centre, 6 feet 9 inches.

The main body panels are of teak. There is a partition framing in the centre of the saloon of figured oak, panelled with ash. With the ends of the saloon framed and panelled with similar woods, and bevelled edge mirrors fixed along the sides and at ends above the windows, the spacious saloon looks very effective.

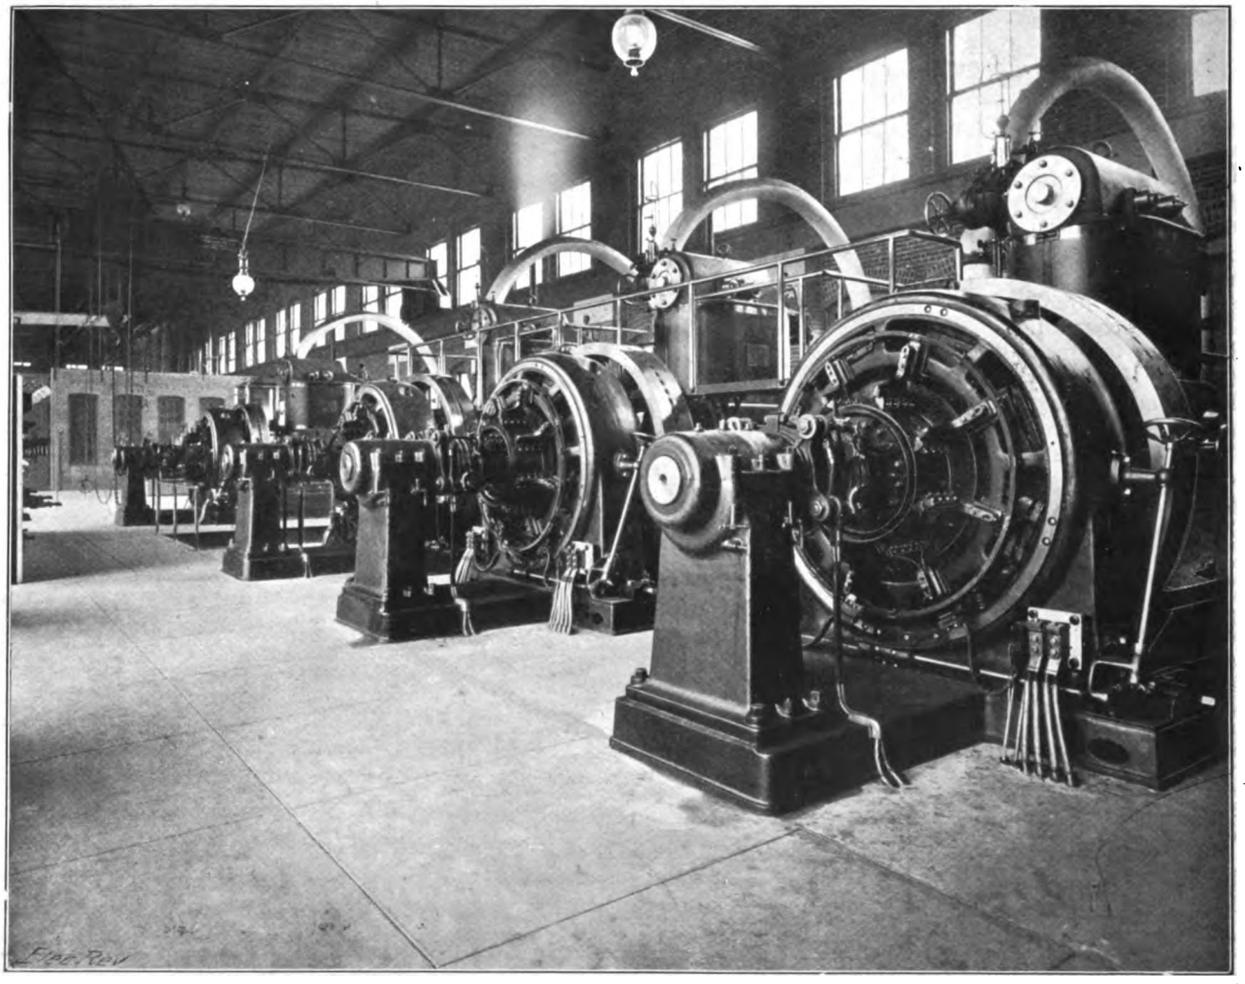
There is a lamp fixed over the canopy at each end of the car, fitted with plate glass at the bottom and bull's-eye 12 inches diameter at the front, provided with interchangeable coloured slides. A hole is made in the canopy for the lamps to fit in so as to throw a light on the platform.



Electrical Equipment of a Great Railway Terminus.—Boilers. (See page 363.)

The present equipment replaces all the conduit system, and extends from Cocker Street (north end of the Promenade) to Victoria Pier (at the south end) and also along Station Road and Lytham Road. Our illustration gives a very good idea of the appearance of the Promenade with the overhead system of construction.

As a general rule, the length of the bracket arm from the post is 4 feet 6 inches, increasing at parts to 6 feet. At one portion of the line there is a distance from the nearest tramway rail to a line plumb down from the overhead line of 15 feet 6 inches, and yet cars have run over that portion of the line with the trolley (at night) at a speed of 25 miles an hour. Of course, considerable difficulties have arisen from time to time. The first trouble was with the insu-



Electrical Equipment of a Great Railway Terminus.—Generating Plant. (See page 363.)

Digitized by Google

lation of the trolley standards; that has now been got over. The next one was with the trolley heads; in order to get over this, Mr. Quin has had to design a new head, but as this is not yet working, we can give no details of its construction. The leakage of current with the conduit system was at times abnormal; in fact, a heavy shower of rain on many occasions multiplied the output by eight. When it went beyond this it pulled the dynamos up. A shower of rain has now no appreciable effect. As regards the financial side of the question, it seems highly probable, if things go on as they are going, that the year's profits will be able to pay, with the increase over last year, from one-third to half the cost of adopting the overhead system. At present the receipts are some £3,500 greater than they were this time last year, this being due to a quicker and more reliable service. No change whatever has been made in the generating plant except to couple the tandem dynamos in series instead of parallel, the pressure of the old conduit system being 250 volts, of the overhead 500. Short extensions are to be carried out directly after the present season, and further large extensions after the next season, specifications for which work will be issued shortly. The generating plant in the works, other than tramway plant, consists of Ferranti, Leeds and London, E.C.C., and Parsons turbo-alternators; the total normal working capacity is 1,350 KW., of which 550 KW. are given by Parsons alternators. The whole of these machines are run in parallel, and although there were some initial difficulties, these have been overcome, and it is now possible to run any two of them, or any combination of them, in parallel, and leave them on their governors.

We have to thank Mr. Quin for his kind assistance in preparing this description, and for several excellent photographs; as well as the various contractors who carried out the work.

THE ELECTRICAL EQUIPMENT OF A GREAT RAILWAY TERMINUS.

THE equipment of the Great South Terminus of the Boston Terminal Company, U.S.A., possesses many features which will be of interest to electrical engineers on this side of the Atlantic. We are also inclined to think that the up-to-date equipment at Boston furnishes a valuable object lesson to the great trunk lines of this country, which are of recent years showing signs of useful advance in the application of electricity to lighting and power purposes—more particularly the former.

The Boston Terminal Station differs from the great railway stations to be found on this side, inasmuch as it is the terminus of a number of the great railway services of the States, viz., the Boston and Albany Railroad, the New England Railroad, the Boston and Providence Railroad, the Old Colony Railroad, the New York, New Haven and Hartford Railroad. The vast local and through traffics which have to be dealt with on these several lines made it necessary that the terminal station should be of dimensions which render it the largest of its kind in the world.

Among the many uses to which electricity is put here may be mentioned arc and incandescent lighting, electric driving, electric elevating, ventilating, and electro-pneumatic switching and signalling. By the kind assistance of Mr. George B. Francis, the resident engineer, we have been enabled to compile from various sources the following notes regarding the installation.

When the engineers took the construction of the station in hand in 1896, it was decided, says Mr. Francis in a paper read this year, to so build it, that the new motive powers, electricity and compressed air, one or both, could be used therein; that a large increase in suburban trains, due to smaller train units and more frequent service, could be had; and that every effort possible should be made to remove the handling of baggage from the passenger platforms.

As to the lay-out of the numerous tracks and buildings we are not much concerned in this article, but with respect to the immense switching system which must be maintained at so large a terminus, we observe that Mr. Francis says: "If the coming motive power is electricity, through a third rail," this will not conflict with the present switching arrangements.

Not the least of the station problems most vital to the successful operation of the station is the track arrangement necessary just outside of the station for the safe and expeditious handling of the trains. An actual count at the old stations indicates about 4,000 movements in 18 hours each day through the switches. By the simple arrangement adopted the station may be operated as a unit, incoming trains on one side, and out-going trains on the other side, or in four sections, one for each of the four main lines.

The switching and signalling system includes a very complete installation of Westinghouse electro-pneumatic interlocking apparatus for handling all the trains using the station to and from the main train shed, and for the frequent trains which are to use the tracks in the suburban loop. The switches and signals, according to a recent description prepared by Mr. Henry J. Conant, the Boston agent for the contractors, are both operated by compressed air furnished from the power house, and the operating mechanism is controlled electrically from interlocking machines in the towers. We hope to refer at greater length to this signalling system at a later period. We may here incidentally remind our readers of the recent announcement of an experimental trial of the Westinghouse electro-pneumatic system on the Great Eastern Railway near Bethnal Green junction.

In June, 1897, a contract was made for the general mechanical and electrical equipment of the station, divided into the following heads:—Interlocking plant and signals, boiler plant, engine plant, ice plant, lighting (arc and incandescent), heating, cold water and refrigeration, ventilation, hot water for cleaning, air for brake testing, elevators, steam heat for cars, protection for roof conductors, fire protection and pumping plant.

At the station there are 235 arc lights, enclosed pattern; about 6,000 incandescent lights, 1,200 of which are in the main waiting room; 25 electric elevators, 10 steam boilers, four electric generators, nine compressors, 45 electric motors, 20 heating and ventilating fans, 25 steam engines, and one travelling crane.

The power plant from which current, &c., for the various purposes is derived, is laid out in what may be termed "tandem" fashion, beginning at the northern end, with the ice and refrigerating plant, the ammonia and air compressors coming next, the engine and dynamo room next, *en suite*, with the stack, economisers, central heating plant and the boiler room, while beyond all, to the south, is the Pintsch gas plant.

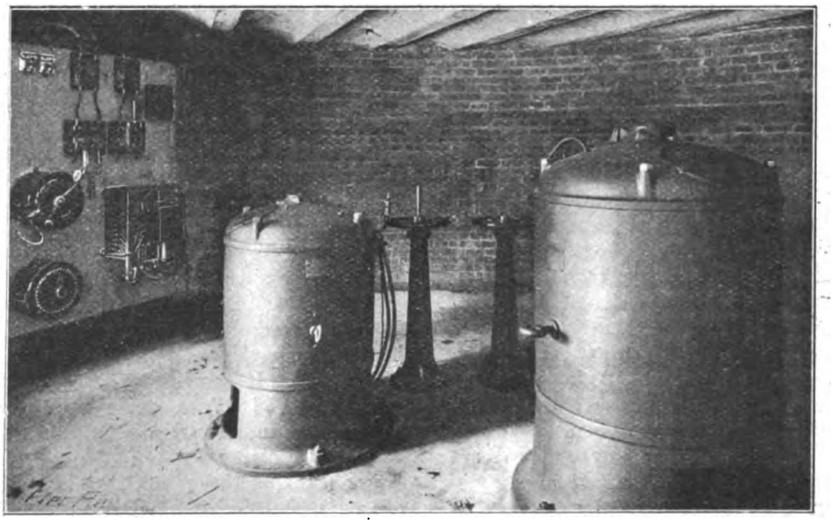
The boiler house equipment, as shown in one of our illustrations, comprises 10 boilers, horizontal return tubular type, 72 inches in diameter and 18 feet long. They are made from an extra quality of steel specially rolled, and are designed for a working pressure of 150 lbs. per square inch. The furnaces are provided with an equipment of Roney mechanical stokers, and are adapted to burning widely different qualities of fuel, including "front ends" from locomotives, and either high or low grade coals, with the greatest possible economy and without smoke. The waste gases are passed through a pair of improved circulating economisers, with dampers and by-pass so arranged that they may be operated singly, in parallel, or in series with each other, as the conditions of service may allow, thereby permitting the greatest possible saving to be made at all times. Draught is furnished by a pair of large, slow-running fans, either of which is of sufficient capacity for the entire plant. The products of combustion, cooled by the economisers to a point at which natural draught could not be employed (except by the use of a chimney so large that its cost would be prohibitive), are discharged at a point a few feet only above the roof of the boiler house through a short and inconspicuous stack. Provision has been made for a substantial increase in boiler capacity whenever required, and consideration has also been had to the future installation of coal handling machinery so far as expedient to do so.

The engine house plant was recently described in the *Electrical World and Engineer* by Mr. H. W. Weller, to whose account we are indebted for some of the following notes:—

There are four units, each consisting of a 375-H.P. Westinghouse compound engine, with cylinders 18 inches and 30 inches in diameter by 16 inches stroke, running at 250 revo-

Digitized by Google

lutions per minute, with steam at 125 lbs. per square inch. Each engine, as will be seen from our illustrations, is coupled to a Westinghouse 8-pole direct current 220-volt compound wound generator. These generators are fitted on the commutator end with four collector rings tapped at quarter-phase intervals into the armature winding, the brushes bearing upon them being connected to two balance coils through which the neutral wire of the three-wire system is brought in to the machine winding. The machines are built with the fields split vertically, so that they may be moved laterally away from the armature, and on account of the three-wire feature the series coils of the compound winding are divided, there being two series coils on each pole, one connected in the positive end and the other in the negative end of the machine circuits.



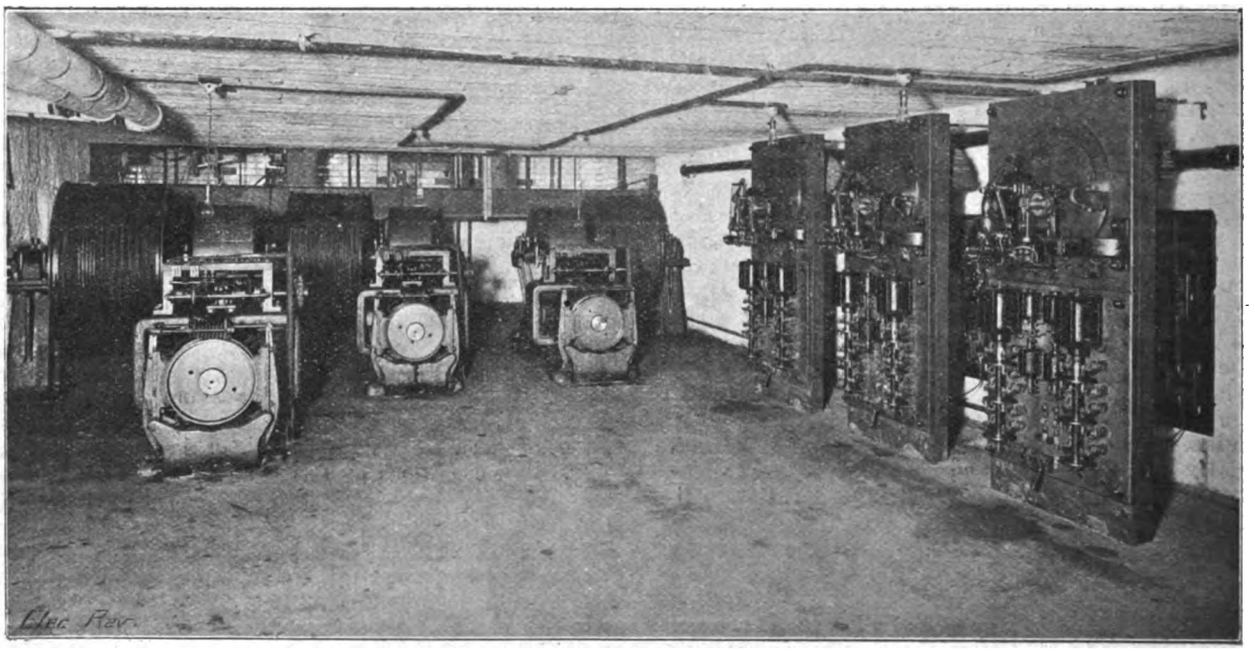
Sump, Showing Vertical Motors.

The engines are connected to the steam mains by bends, and an 8-inch pipe connects each to the exhaust. The engines are run non-condensing, and the exhaust is taken into the central heating plant for general purposes, but otherwise they are run condensing. Proper iron platforms and stairways are constructed round the engines to facilitate the work of the attendants, the platforms of the three engines nearest the boiler room being connected together for convenience. Space is provided for two more similar units if the additional power is required in the future.

28 inches by 24-inch stroke. The exhaust from the engines is brought to it by a 16-inch steel main on the west side of the basement, the main exhaust passing to the central heating plant through an 18-inch steel pipe. Arrangement is made for a free exhaust into the atmosphere if necessary.

The switchboard for the electrical instruments is of polished white marble securely bolted to an iron framework on the west side of the engine room. It consists of 13 panels. The station panel has mounted upon it two Weston standard voltmeters with illuminated dials, showing the E.M.F. on the two sets of bus bars. One Weston station voltmeter with an illuminated dial is carried on a swinging bracket, and can be thrown on any generator by the use of a plug switch. There is also a circular-pattern Weston ammeter, showing the unbalanced load on the neutral or balance wire of the system. A set of annunciators is installed, connected with the various centres of distribution for the lights, showing which centre is calling for current.

There are four pairs of machine panels, one for each generator, one of each pair being connected to either side of the system. The positive contains the field rheostat, a circular Weston ammeter, a magnetic cut-out switch or circuit breaker, which opens the positive line and also the positive equaliser; also a main



Elevator Machinery.

A handsome gauge-board of polished white marble, supported on iron standards, is placed on the east side of the engine room, containing five polished brass gauges, showing, respectively, the boiler pressure, air-interlocking, vacuum, back pressure, and air-brake testing pressure.

In the basement of the engine room are installed the four balance coils for the generators and also the condenser. This is a jet condenser and pump made by the Deane Steam Pump Company, of Holyoke, Mass., with cylinders 18 inches and

switch controlling both the positive and negative side of the machine, and the positive and negative equaliser. This switch is double-throw, and can connect the machine to either set of bus bars. The two sets of bus bars are provided in order that two different potentials can be carried at the same time, and so that machines can be run in multiple or separately on different services. On the negative panel of each pair is another magnetic circuit breaker, which opens the negative side of the line and the negative equaliser.

Digitized by Google

There are also four feeder panels containing the various double-throw pole switches for throwing each feeder circuit to either of the two sets of bus bars. These panels also contain the various circular-pattern voltmeters operated by pressure wires from the several centres of distribution, showing the power-house attendant at all times the actual E.M.F. at the various distribution boards.

A polished white marble gangeboard is installed in the office of the superintendent of the power plant, containing five Bristol recording gauges for the steam, compressed air for interlocking, compressed air for air-brake testing, E.M.F. on the high potential, and the E.M.F. on the low potential bus bars.

There are 16 two-wire feeders on the 220-volt circuits, running from the main switchboard at the power house, 12 of these leading to the various centres of distribution, and used for lighting purposes only, the other four sets of feeders being for motor service. There is also the balance or neutral wire of 400,000 C.M., running from the balance coils in the basement, making a complete loop around the station buildings, and taking in all the centres of distribution. The arc and incandescent lamps are connected across from either wire of the 220-volt feeders to the balance or neutral wire, giving them an E.M.F. of 110 volts.

The 12 lighting circuits are divided as follows:—No. 1, the public incandescent lights, such as waiting rooms, lavatories, &c.; No. 2, the basement lights, fan rooms, cellars, &c.; No. 3, the restaurants and other tenants; No. 4, the inward baggage rooms; No. 5, the outward baggage rooms; No. 6, public arc lights, including the train shed; No. 7, suburban platforms in subway; No. 8, office lighting; No. 9, suburban tunnels, both incoming and outgoing; No. 10, the express companies' buildings; No. 11, power house, gas plant, &c.; No. 12, interlocking towers and sump lighting.

At the above centres of distribution are located slate switchboards, provided with the necessary triple-pole switches, which control the various lighting circuits of that centre. A pilot lamp indicates the presence of the current, and a push button signals to the power house when current is required.

There are over 6,000 110-volt incandescent lamps installed. They are Sawyer-Man high efficiency 3·1-watt lamps, and have a regulation within 2 per cent. There are also upwards of 250 enclosed long-burning arc lamps, supplied by the Jandus Electric Company, which consume about 5 amperes at 110 volts. These are used for lighting the train shed, baggage rooms, entrance, and for lighting outside the station under the sidewalk awnings.

The motors are fed from the 220-volt circuit, and the following distribution of the circuits has been arranged:—One operating all the elevators and baggage lifts, except the elevator for the ice plant; one operating the basement fan motors for warm-air heating, another for the ventilating motors and attic fans, and the remaining one for the sump motors and the ice plant.

The various feeders are carried along the roof and sides of the tunnels used for the heating mains, and along the basements of the baggage and waiting rooms, being supported on porcelain insulators, and suitable racks where necessary. The main waiting room is lighted in a very pleasing and artistic manner, harmonising with the architectural features. There are 33 15-light clusters enclosed in opalescent globes, at the intersections of the deep ceiling beams, and 48 10-light clusters, besides 228 side bracket lights, or over 1,200 lights in this waiting room. The fixtures throughout are specially designed and very handsome, those in the grand dining room being of bronze.

In connection with the heating and ventilation arrangements, there are six blower fans or blast wheels for forcing external air through the heaters situated in the various basements. These fans are operated by means of belt from six standard Westinghouse multipolar motors ranging from 5 to 30 H.P. each. Eleven special slow speed vertical motors, varying from 1 to 8 H.P. are direct connected to the same number of attic fans in the roof to insure perfect ventilation. An electric elevator is employed for taking ice from the tank room to the ice house. This is of the Morse belted pattern, operated by a Westinghouse multipolar motor.

There are seven electric passenger and 12 electric baggage elevators, all of which were furnished and installed by the Sprague Electric Company of New York. The elevator machines are seen in one of the pictures. The passenger elevators are located in the head house, and serve the general offices, restaurants, &c. Four of these have a car rise of 70 to 80 feet, and their individual capacity is 4,000 lbs. at a speed of 200 feet per minute, or 250 feet with an average load. The motors are rated at 20 H.P. at a speed of 470 revolutions per minute, but they are readily capable of 50 H.P. for a short time. There are two elevators with a capacity of 2,000 lbs. each at a speed of 100 feet per minute, the car rise being 11 feet and 32 feet respectively. The other passenger elevator has a car rise of 18 feet and a capacity of 2,500 lbs. at 150 feet per minute.

The 12 baggage elevators, or lifts, have an average car rise of 16½ feet, and a capacity of 3,000 lbs. at 15 feet per minute. These were specially designed for the duty required, and the limited space available. They are placed in pockets or pans built of steel plates, formed in the top platform level, and just large enough to receive the hoisting machines and drums. These are built up on 12-inch channel irons, framed into the platform structure at one of the short ends of the well. The motor used is rated at 12 H.P. at 750 revolutions per minute. Steel worms on either end of the motor shaft mesh into bronze gear wheels. The shafts of the worm wheels are direct connected by flanged couplings to the two drum shafts extending along either side of the well. On each shaft are two chain drums, upon which are wound the chains fastened to each corner of the elevator platform. The worm wheels are cut right and left to take up all of the end thrust. Automatic "limits" are geared to one of the gear shafts, and two-foot pushes are provided at each end of the platform, one for the "up" motion, and the other for the "down."

At each gate at top and bottom are placed push buttons for bringing the car to that landing, providing it is not already in service, and the gates are all closed. Automatic locks and safety switches break the circuit, and prevent the movement of the car until everything is secure at the landing. The gates are also automatically locked, except when the car is at that landing, in which case they are automatically released.

Of the above lifts, four are located in the baggage rooms on either side of the train shed, five between the train tracks at the onter end of the shed, and the other three between the tracks at the head house end of the train shed.

The suburban loops and a large portion of the basements are below tide water, so that the disposal of water from the large extent of waterproofed structure involved somewhat unusual considerations. Mr. Conant, in the paper already referred to, says that a large sump well was built near the power house, in which electrically-driven centrifugal pumps were installed (see illustration) to pump away any possible seepage, storm water, and melting snows, which, owing to the grades of the suburban track, will necessarily be carried to the lower levels. The electrical pumping apparatus is controlled automatically by the level of the water in the sump, and a large reserve pump is provided to handle unusual quantities of water. Electric alarms are also provided to notify attendants to start the large pump whenever the water might reach a predetermined danger level.

The entire equipment mentioned in this article was, we understand, carried out by Messrs. Westinghouse, Church, Kerr & Co.

We have to express our indebtedness to Mr. Francis, the resident engineer, for the photographs accompanying this article, and to the papers by Messrs. Francis and Conant, as well as to the *Electrical World and Engineer*, for the material from which this description has been compiled.

Warning.—We are asked to publish a warning to electrical business people in London so that they may be on their guard against a certain probable visitor. The man in question has already entered several electrical establishments to talk business under the pretence that he has orders to place, and after being taken out to dine in the usual way has told a very plausible story and secured a small loan. Needless to say he has never reappeared to repay his indebtedness.

NOTES.

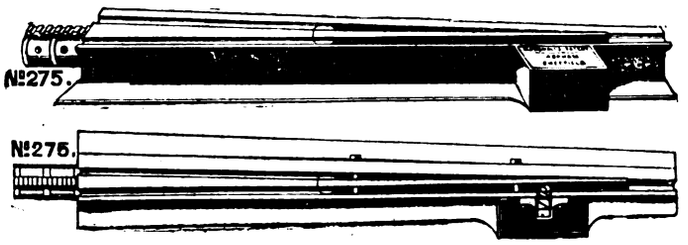
(*Continued from page* 358.)

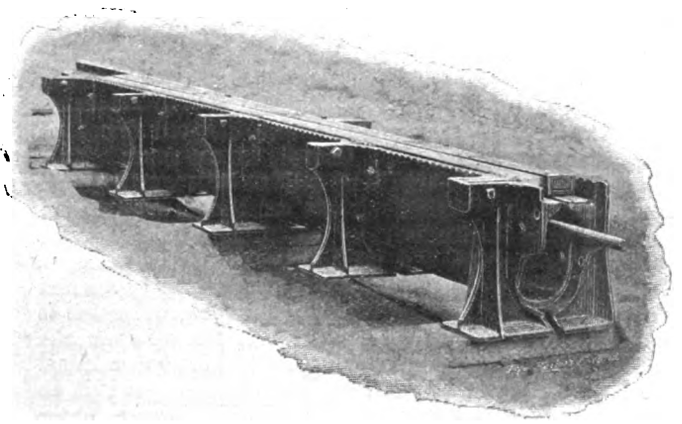
Re "Cassier's Magazine" Electric Railway Number.—Messrs. Laing, Wharton & Down, Limited, send us the following:—

Doubtless many of your readers will read or look through this production, and we, therefore, take the liberty of correcting two errors that are very potent and annoying to us. On both pages, 296 and 325, the overhead equipment is ascribed to Messrs. Greenwood and Batley, who will at once inform you that this is not a fact. We carried out this work under our chief engineer, Mr. Justus Eck, direct for the Leeds Corporation, and if you will refer to your back numbers, we think you will find this mentioned therein. The fullest detail, if our memory serves us right, was given in the *Railway World* of September, 1897, and this remains unqueried to this day.

We take the liberty of calling your attention to this matter, as the *Magazine*, having no correspondence columns, is not well able to make corrections, and we feel that the subsequent number will not have the same circulation and attention as the current one.

Blackpool Tramways.—We give below an illustration of the spring points referred to in our article on the above tramways, as well as of the "Mapple" patent conduit which was supplied by Messrs. Askham Bros. & Wilson for the Station Road section. This conduit is made in sections, each complete in itself, and is so arranged that the steel





channel rail which forms one side of the slot can be raised on hinges. In this way access is readily obtained to the interior of the conduit, and to the insulators, which are bolted to the other (fixed) channel rail. The conduit consists entirely of iron, and is 16 inches deep by 10 inches wide. It is claimed that, amongst other advantages, the ease of repair without interruption to traffic forms a most valuable feature of the system.

More English Orders for America.—A daily paper reproduces the following comments from the *New York World*, in which it refers to and endorses Lord Kitchener's speech at the opening of the Atbara Bridge:—

We are in a position to state that a representative of one of London's greatest industrial and financial concerns is returning to England to-morrow, after having placed an order here for several million dollars' worth of machinery. He confesses that this was of such delicate construction that no shop in England is capable of producing it. A part of his order was for 36 locomotives, and he predicts that he will make frequent trips on similar errands to the United States.

Automobiles at the British Association.—Arrangements for the automobile exhibition in connection with the Dover meeting of the British Association are in an advanced state, and prospectuses regarding space for exhibits, prizes, and general details, have been circulated. The exhibition, organised with the co-operation of the Automobile Club of Great Britain, and under the controlling influence of the Mayor, Sir W. H. Crundall, J.P., who is chairman of the Managing Committee, will be held for three days, from Tuesday, September 19th, to 21st, towards the close of the Association meeting. There are to be certain competitions as to running, control, economy of fuel consumption, design, &c., the Judging Committee for this purpose being as follows:—Mr. W. Worby Beaumont, Prof. C. Vernon Boys, Mr. H. Graham Harris, Major Holden, Sir W. H. Preece, Mr. Boverton Redwood, Prof. Hele Shaw, and Mr. James Swinburne. All communications should be addressed to Mr. F. E. Beeton, the secretary, at Park Street, Dover.

Partnership.—We are informed that the partnership hitherto subsisting between Mr. Reginald Wilson and Mr. W. H. Story, under the name of "Wilson & Story," and carrying on business at 66, Victoria Street, S.W., has been dissolved. In future the business will be continued by Mr. Wilson alone, at the same address, under the style of "Reginald Page Wilson."

British Association.—Among the arrangements for the British Association meeting at Dover is a lecture on the 18th inst., by Dr. Fleming, on the "Centenary of the Electrical Current." It is stated that the lecture has been fixed for this day so as to be coincident with the congress of electricians at Como. It will deal with wireless telegraphy, and be illustrated by experiments.

Effects of Lightning.—The United States Weather Bureau has just issued a statement (which is abstracted in the *Western Electrician*) of damage to property and loss of life by lightning in the United States during the last nine years, from which it appears that 312 persons are killed annually by lightning stroke in that country, taking a fair average. In this respect the worst year was 1895, when 426 Americans were destroyed in this way; in 1898 the mortality was 367. In nine years, from 1890 to 1898, inclusive, five individuals in every million of the population of the United States were killed by lightning. The danger from this cause seems to be least in large cities and in thickly populated districts. Agricultural labourers furnish the most victims. Ohio is the greatest sufferer, the death rate by lightning in that State being 24 in every 100,000 persons of the farming class. The greatest proportion of fatal strokes is found in the Missouri Valley, on the Great Plains, and in the Rocky Mountain region. In 1898 no fewer than 1,866 buildings were damaged or destroyed by lightning involving a loss of $1,446,880. During the same year lightning killed 964 cattle, 306 horses, 30 mules, 116 pigs and 426 sheep, representing a total value of $48,257. All of this destruction of farm animals was accomplished by only 710 "strokes." Much of this damage might be avoided by grounding wires at suitable intervals along lines of barb wire fences, which are sometimes deathtraps to stock, the fatal shocks being inflicted often through the medium of the wires at a considerable distance from the point hit. So far as human beings are concerned, practically all of the deaths occur during the five months from April to September, the highest record being in June and July.

Personal.—Dr. J. T. Bottomley, F.R.S., has resigned all his appointments at the University of Glasgow, and now intends to devote his whole attention to consulting work in electrical engineering. While we regret that the University will no longer have the benefit of Dr. Bottomley's teaching, we feel that in his new sphere of action his scientific attainments will have greater scope, and we wish him a long and successful career as a consulting engineer.

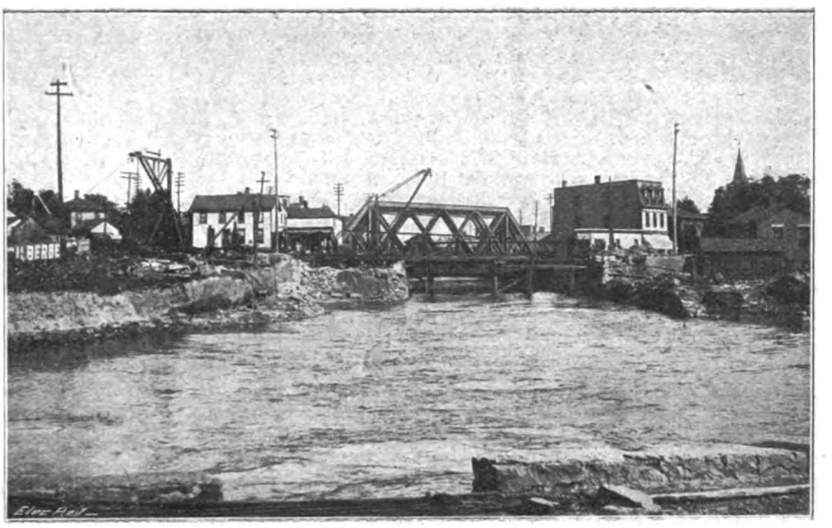
Niagara Falls.—The Niagara Falls Hydraulic Power and Manufacturing Company is displaying the usual energy this summer in the deepening and widening of the surface canal that carries water from the upper Niagara River to the forebay on the edge of the bluff of the lower river, from which forebay the turbines in the power house at the water's edge in the gorge are supplied. The length of the canal is about 4,400 feet. The entrance is about 250 feet wide, but in a few hundred feet of length this narrows down to 70 feet. For a portion of the width of the canal the channel is 8 feet deep, and for the remainder it is 14 feet deep. Drill boats and dredges are now at work adding to its water-carrying capacity, but probably the most notable improvement now being made is in and about the basin of the waterway. This basin is located 300 feet back from the edge of the bank, and is connected to the forebay by two canal feeders. In the past this basin has been of comparatively limited dimensions, but now the line of the banks is being broken away and the basin has been turned into quite a bay fronting on the various mills that stand between the basin and the edge of the bank. This work of enlarging the canal basin is still under way, the picture well portraying the improvement. At the point where Main Street crosses the canal a new bridge with a span of 100 feet in the clear is being put in, and the canal widened from 70 to 100 feet at that point. A close inspection to the left of the bridge will show the old and new walls of the canal. The canal basin has been deepened, and when all the work has been finished for the summer the capacity of the waterway will have been materially enlarged. All this work is under the personal supervision of Wallace C. Johnson, M.Am.Soc.C.E., who is chief engineer of the Niagara Falls Hydraulic Power and Manufacturing Company.



A New Method of Forced Draught.—This system was described in a paper before the Institute of Naval Architects at Newcastle by Mr. Nelson Foley. It consists in forcing the air into a box placed across the furnace front and into which the ends of the bars are fixed. The bars are hollow and are perforated with numerous small holes along both sides. The forced air escapes at these holes to the fire, and has also an inducing action upon the air in the ash-pit, which is also forced into the fire by this means. The bars can be made in lengths of 4 feet, and it is said they keep cool and clinker does not adhere. Tests have been made showing as much as 72 lbs. of coal consumed per square foot of grate. The jet holes are $\frac{5}{32}$ to $\frac{3}{16}$ inch diameter, and are pitched $\frac{1}{4}$ of an inch apart. The length of grate was only 2 feet 7½ inches. The intensity of the draught was never over 8½ inches, while with 1¾ inches draught the combustion was 29 lbs. per square foot of grate. With 1¼ inches of draught as much as 41 lbs. of combustion was secured, while 40 lbs. was allowed with 1·73 inches of draught. There is not information sufficient to explain the differences of results.

The Thermo-chemical Theory of the Carbon Cell.—More than 10 years ago Donato Tommasi described an electric element in which the electrodes were of carbon, one being coated with lead peroxide, and immersed in a solution of sodium chloride, and he regarded the action as due to the oxidation of the uncoated carbon and the reduction of the peroxide. Reed (Electrical Review, 1896) considered the current to be due to the action of the sodium chloride on the lead peroxide, but this view is untenable, as in that case the coated carbon should be the negative electrode, whereas the reverse obtains. Further, the E.M.F. calculated, according to the author's view of the action, is equal to that actually found for the element. For further details consult the *Bulletin de la Société Chemique de Paris* (III.), Vol. 17, pages 963-964.

The Scourge of Scholarship.—The Vice-Chancellor of Cambridge University, Dr. Alexander Hill, has been condemning the system of granting scholarships. It is time the system was condemned. Under it he finds that boys are overworked, and there is cramming. The early developed brain was selected by the scholarship system. Boys were not properly to be regarded as sheep, which are raised to become mutton at two years, irrespective of the fact that at five years they would be really inferior. But the five years of the sheep is never attained. The sheep has materialised, as intended, at two years. Boys, however, are raised and ripened at 19 years, and this is wrong, for it does them so much harm, that at 49, when they should be at their best, they are done for. Such was the very correct drift of the arguments advanced by the Vice-Chancellor. He advocated a proper regard for athletics as a counterpoise to too much study. Unfortunately, however, no substitute was proposed for the scholarship test, which, we grant, is pernicious enough, and so hard and fast drawn in its rules that we hear boys deplore the date of their birth. Had they been so much younger or so much older they could have got such and such a scholarship. Then a boy whose school career may have been of the best has some trivial complaint on examination day, and he may thereby be thrown out and miss his chance of a university career, which he cannot afford unless with the help of the scholarship. It is a fact that a very considerable proportion of university students who work would not be there but for the pecuniary aid of some exhibition or scholarship. Such pecuniary aid is essential if the universities are to be run on their present lines and retain such workers. At the same time, might not the governors of all public schools devise some better means of awarding scholarships than they now possess, taking into account not simply proficiency at an examination of a few hours, but general conduct during, perhaps, several years, and general capacity? At present, with the narrow system of awarding scholarships, breadth of education is shut out. There is no chance for the all-round boy. The classic who cannot get beyond simple addition in mathematics is able to appear a genius as a scholarship man. The mathematician who only knows various alphabets and letter forms so that he may use the letters in cabalistic formulæ also appears to be possessed of genius until he tries to read or write decent English. The boy, good all round, well read, well balanced, and healthy, has no chance for the best rewards, and it is certain that for good or evil many of the best are thus shut out of the universities, which are too expensive for any not really well-to-do people to afford unaided.

Sheffield Trams.—On Monday next, September 4th, the municipal electric tram system will be publicly inaugurated by the Lord Mayor. There will be special cars run over the section from the Nether Edge to Tinsley for the convenience of the party, and tea will follow at the Town Hall. The public service will commence on Tuesday.

NEW COMPANIES REGISTERED.

Electric Lighting and Traction Company of Australia, Limited (63,334).—This company was registered on August 17th, with a capital of £20,000 in £5 shares, to carry on in Australasia or elsewhere the business of electrical and mechanical engineers, electricians, suppliers of electricity for light, heat, motive power and otherwise, tramway and railway proprietors, contractors, carriers of passengers and goods, &c. The first subscribers (each with one share) are:—R. P. Sellon, 49, Queen Victoria Street, E.C., electrical engineer; W. E. Lane, 14, Durley Road, N., electrical engineer; R. A. Dawbarn, "Wierton," Sidcup, electrical engineer; F. M. Hodson, 14, Harpenden Road, West Norwood, accountant; J. McLachlan, 33, Agamemnon Road, West Hampstead, N.W., assistant secretary; J. Renwick, 29, Hillside Road, Stamford Hill, N., accountant; and G. J. Tindall, 1, Wellington Chambers, York Street, Westminster, articled clerk. The number of directors is not to be less than three nor more than five; the subscribers are to appoint the first; qualification, £250; remuneration, £1,000 per annum, divisible. Registered office, 49, Queen Victoria Street, E.C.

Southport Boating Company, Limited (63,307).—This company was registered on August 15th, with a capital of £1,800 in £6 shares, to adopt an agreement with the Mayor, Aldermen and Burgesses of the borough of Southport, and to build or acquire, repair, sell, let on hire, and otherwise deal in pleasure and racing boats, launches, &c., and to carry on the business of electricians, engineers, suppliers of electricity, and manufacturers of apparatus for the generation, distribution, and employment of electricity. The first subscribers (each with one share) are:—Henry Wright (Stem), 79, Snellfield Road, Southport, fisherman; Thomas Blundell, 116, Shellfield Road, Southport, salesman; William Wright (Jenneys), 40, Shellfield Road, Southport, fisherman; William Wright (Roberts), 12, Shellfield Road, Southport, cabinet maker; Miles Blundell, 121, Shellfield Road, Southport, fisherman; Richard Wright, Bank Nook, Southport, fisherman; and John Blundell, 55a, Shellfield Road, Southport, tailor. The number of directors is not to be less than four nor more than nine; the first are William Wright (Roberts), Miles Blundell, William Wright (Jenneys), and Henry Wright (Stem); William Wright (Roberts) is the first managing director.

Portuguese Tramways Construction Company, Limited (63,337).—This company was registered on August 17th, with a capital of £1,000 in £1 shares, to construct or acquire and maintain any tramways, railways, &c., and to carry on the business of carriers of passengers and goods, suppliers of electricity, electrical and mechanical engineers, &c. The first subscribers (each with one share) are:—J. Jewell, 13, Richmond Crescent, N., clerk; F. Davies, Hillwood, Westcliffe-on-Sea, clerk; A. W. Rogers, 8, Denning Road, Hampstead, N.W., clerk; S. M. Nelson, 20, Sheepcote Road, Harrow, clerk; H. A. Milner, 84, Effingham Road, Hornsey, N., clerk; W. MacGillivray, 368, Green Lanes, N., clerk; and T. A. Barson, 1, Inglewood Road, West Hampstead, clerk. The number of directors is not to be less than three nor more than seven; the first are to be appointed by the subscribers; remuneration, £300 per annum, divisible.

Barnsley and District Motor Car Company, Limited (63,352).—This company was registered on August 18th, with a capital of £5,000 in £100 shares, to build or acquire and work by means of electricity, steam, oil, or other motive power any locomotive and other engines, motor cars, carriages, omnibuses and other vehicles, and to carry on the business of carriers of passengers and goods, electricians, engineers, manufacturers of and dealers in electric, magnetic, galvanic and similar apparatus, &c. The first subscribers (each with one share) are:—Charles Wray, Fair Field House, Barnsley, butcher; E. J. B. Ridcal, Barnsley, solicitor; C. H. Charlesworth, Barnsley, provision merchant; John Harvey, Barnsley, hotel proprietor; William Wray, 14, Cheapside, Barnsley, pork butcher; John Cooke, Beech Grove, Barnsley, butcher; and Joseph Hewitt, Marrow House, near Barnsley, solicitor. Table A mainly applies.

Davy Improved Arc Lamp Syndicate, Limited (63,358).—This company was registered on August 19th, with a capital of £2,100 in £1 shares, to adopt an agreement with W. J. Davy and to carry on the business of electrical engineers, arc lamp manufacturers, electric light makers, &c. The first subscribers (each with one share) are:—J. W. Lee, Budleigh, Salterton, Devon, colonel; C. Bhould, Finsbury House, E.C., clerk; L. H. Wilkins, Finsbury House, E.C., accountant; F. R. Redgrave, 41, Burnley Road, Stockwell, S.W., accountant; J. Cassidy, 95, Holbeen House, Chelsea, clerk; J. J. Bye, 126, Laburnum Street, Kingsland Road, N., clerk; and J. Gordon, 80, Birchanger Road, South Norwood, clerk. The number of directors is not to be less than two nor more than nine; the subscribers are to appoint the first; qualification, 200 shares; remuneration as fixed by the company.

Electrical Wool Pulling Syndicate, Limited (63,360).—This company was registered on August 19th, with a capital of £15,000 in £1 shares, to acquire certain patents for improvements in methods of and apparatus for removing wool or other hair from skins. The first subscribers (each with one share) are:—Seth L. Johnson, 10, Billingsley Terrace, Bradford, manager; W. R. Jones, Boldshay Street, Bradford, wool puller; S. Brooksbank, 63, Bramsley Road, Frizinghall, salesman; E. Johnson, 107, New Cross Street, West Bowling, Bradford, accountant's clerk; H. Goodwin, 7, Grantham Terrace, Bradford, wholesale paper hanging dealer; J. Clayton, 310, Wakefield Road, Bradford, wool and waste merchant; and Mrs. Ellen Johnson, 10, Billingsley Terrace, Bradford. The number of directors is not to be less than two nor more than five; the first are to be appointed by the subscribers; qualification, £250; remuneration as fixed by the company.

Street Lighting Company, Limited (63,388).—This company was registered on August 23rd, with a capital of £30,000 in £1 shares, to adopt an agreement with the Liverpool Meter Company, Limited, and its liquidators, and to carry on the business of mechanical and electrical engineers, ironfounders, brassfounders, millwrights, metal workers, suppliers of gas and electricity, metallurgists, and manufacturing chemists. The first subscribers (each with one share) are:—D. de Ybarrondo, 8, Tower Chambers, Liverpool, merchant; A. S. Hannay, 24, Hacking Hey, Liverpool, cotton broker; J. T. Binning, Phœnix Chambers, Liverpool, underwriter; T. E. Hassell, Queen Insurance Buildings, Dale Street, Liverpool, sharebroker; G. H. Brown, Exchange Court, Liverpool, cotton broker; R. H. Smith, Manchester Buildings, Liverpool, produce broker; F. M. Radcliffe, 9, Cook Street, Liverpool, solicitor. The number of directors is not to be less than three nor more than four; the first are Domingo de Ybarrondo, Anthony S. Hannay and Arthur H. Holme; qualification, £500; remuneration, £100 each per annum (200 for the chairman) and a share in the profits.

Julius Sax & Co., Limited (63,371).—This company was registered on August 21st, with a capital of £18,000 in £1 shares (12,000 preference), to acquire the electrical business of a company of the same name (incorporated in 1892), to enter into an agreement with H. M. Salmony, and to carry on the business of electric light and power contractors, electricians, electrical and mechanical engineers, &c. The subscribers are:—G. Arbuthnot, 52, Eaton Place, S.W., gentleman, 5,000 preference shares; L. G. F. Oppenheim, 40, Great Cumberland Place, W., gentleman, 5,000 preference shares; H. M. Salmony, 119, Coldharbour Lane, Camberwell, S.E., electrical engineer, one ordinary share; A. Bannister, 48, Ambler Road, N., gentleman, one ordinary share; L. Moss, 22, Austin Friars, E.C., gentleman, one ordinary share; L. Wolff, 22, Austin Friars, E.C., gentleman, one ordinary share; T. E. Cowan, 18, Austin Friars, E.C., solicitor, one ordinary share. The number of directors is not to be less than three nor more than five; the first are the first three subscribers; qualification, £1,000.

Dick, Kerr & Co., Limited (63,407).—This company was registered on August 24th, with a capital of £350,000 in £5 shares (30,000 5 per cent. cumulative preference), to adopt an agreement with Dick, Kerr & Co., Limited (incorporated in 1890), and to carry on the business of manufacturers of and dealers in railway and tramway appliances, rolling stock, engines and machinery of every description, iron and steel founders, electricians, engineers, contractors for public and other works, &c. The first subscribers (each with one share) are:—C. T. Cayley, Constitutional Club, S.W., engineer: J. Kerr, 110, Cannon Street, E.C., contractor; J. Gane, 66, Coleman Street, E.C., chartered accountant; G. Flett, 110, Cannon Street, E.C., contractor; H. T. Crewe, 78, Queen Victoria Street, E.C., engineer; H. Brown, 2, Bond Court, Walbrook, E.C., solicitor; and G. W. Carr, 110, Cannon Street, E.C., secretary. The number of directors is not to be less than two nor more than seven; the first are Claud T. Cayley, David C. Ellis, John Kerr, and G. Flett: qualification, £500; remuneration, £150 each per annum and an extra £150 for the chairman. Registered office, 110, Cannon Street, E.C.

Gramophone Company, Limited (63,411).—This company was registered on August 25th, with a capital of £150,000 in £1 shares, to acquire and take over as a going concern the business carried on at 31, Maiden Lane, W.C., and elsewhere, as "The Gramophone Company," to adopt an agreement with Edmund T. L. Williams and William B. Owen, to manufacture and deal in gramophones, phonographs, mutoscopes, biographs, mutographs, and electrical and scientific apparatus of all kinds, and to carry on the business of a telephone, telegraph, and general electric supply company. The first subscribers (each with one share) are:—E. T. L. Williams, 1, Clements Inn, W.C., solicitor; W. B. Owen, Albany Lodge, Esher, merchant; Miss J. M. T. Lewis, 49, West Cromwell Road, S.W.; P. H. Bohanna, 34, Hambalt Road, Clapham, agent; T. D. Addis, 98, Petherton Road, Highbury New Park, N., clerk; G. F. Long, Heath Lodge, Fernham Road, Thornton Heath, accountant; and B. G. Royal, 41, Gower Street, W., engineer. The number of directors is not to be less than three nor more than eight; the first Edmund T. L. Williams, William B. Owen, and Emile Berliner (permanent directors; special qualification, 10,000 shares); qualification of ordinary directors, 1,000 shares; remuneration, £300 per annum, and a share in the profits, divisible (maximum £1,000).

"Perfect" Arc Lamp and Accessories Company, Limited (63,414).—This company was registered on August 25th, with a capital of £10,000 in £1 shares, to enter into an agreement with F. R. Hill & A. V. Gifkins, to manufacture and sell in Great Britain only, the "H. & G." high tension switch, to deal in the "Perfect Arc Lamp," to manufacture, sell, and deal in incandescent lamps, engines, dynamos, motors and electric fittings and supplies, and to carry on the business of electrical and mechanical engineers, electricians, &c. The first subscribers (each with one share) are:—H. Bourne, Lancaster Lodge, Wandsworth Common, S.W., gentleman; H. A. Caspard, 147, Lower Addiscombe Road, Croydon, clerk; T. G. Wallace, 58, Winchester Street, Pimlico, electrician; G.

Hobley, 41, Chetwynd Road, Highgate Road, N.W., clerk; F. E. Janes, The Lawns, Sevenoaks, solicitor; C. S. Lickfold, 1, Draper's Gardens, E.C., gentleman; and J. M. Lickfold, 51, Doughty Street, W.C., secretary. The number of directors is not to be less than two nor more than five; the first are F. R. Hill, H. Bourne, A. W. Scrivener, and W. N. Stewart; qualification, £500; remuneration, £200 each per annum. Registered office, 32, York Street, Westminster.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Electrical Construction Company, Limited (39,292).—This company's annual return was filed on August 11th, when 112,100 ordinary and 25,000 preference shares were taken up out of a capital of £400,000 in 150,000 ordinary and 50,000 preference shares of £2 each. 2,100 ordinary and 11,855 shares have been paid for in full, and the remaining 110,000 ordinary and 13,145 preference are considered as fully paid.

F. H. Royce & Co., Limited (41,362).—This company's annual return was filed on July 14th, when 6,000 preference, 21,480 ordinary and 500 deferred shares were taken up out of a capital of £60,500 in 6,000 preference shares of £5 each, 30,000 ordinary shares of £1 each and 500 deferred shares of £1 each. £1 5s. has been called up on each of the £5 shares, and the full amount on 9,466 £1 shares, resulting in the receipt of £16,966. The remaining 12,514 £1 shares are considered as fully paid.

British Thomson-Houston Company, Limited (47,982).—This company's annual return was filed on August 4th, when 24,000 shares were taken up out of a capital of £400,000 in 40,000 £10 shares; £165,310 has been paid on 16,531 shares, and 7,469 are considered as fully paid.

Crompton & Co., Limited (27,200).—This company's annual return was filed on August 2nd, when 32,098 shares were taken up out of a capital of £162,000 in 54,000 £3 shares. £3 has been called up on 30,098 and £90,044 has been received, leaving £250 still due. 2,000 shares are considered as fully paid.

D. P. Battery Company, Limited (44,084).—This company's annual return was filed on July 26th, when the entire capital of £10,000 in £1 shares was taken up. £1 has been called up on each of 8 shares, and 17s. on 9,992, resulting in the receipt of £8,501 4s.

Coventry Gas Fittings, Electrical and Engineering Company, Limited (22,431).—This company's annual return was filed on July 26th, when the entire capital of £15,000 in £1 shares was taken up. 14,500 shares have been paid for in full, and the remaining 500 are considered as fully paid.

West African Telegraph Company, Limited (21,626). This company's annual return was filed on July 26th, when 23,109 shares were taken up out of a capital of £400,000 in £10 shares. £231,090 has been received.

CITY NOTES.

The Chloride Electrical Storage Syndicate, Limited.

The ordinary general meeting of this syndicate was held at Clifton Junction, near Manchester, on Tuesday, 29th ult., Dr. F. H. Bowman presiding.

In moving the adoption of the report and accounts, the Chairman said the shareholders would notice that the course of the company during the past year had been one of steady progress. The storage battery continued to give the greatest satisfaction, and orders had begun to pour in. Nothing could hinder electrical storage from being required all over the country. There were already signs that it would be used for electrical traction on all tramcar routes in the centre of cities. He had no hesitation in saying that the company's battery was by far the best in the market, and the only one that could be called commercially successful at the present time. From the balance-sheet the shareholders would see that after providing for debenture interest they had a sum of £16,390, which the directors considered very satisfactory, taking into consideration the rise in the price of zinc and lead, of which large quantities were used in the works. After writing off £5,160 from the various accounts, there remained at the disposal of the company £11,229. Dividends had absorbed £3,703 of this, and the directors proposed to carry forward £7,526, and to declare a further dividend out of that money at the rate of 7 per cent. Further capital would be required owing to the great extension of the business, and it was proposed to raise that by a further issue of debentures. Although he would have liked to report greater success, still the balance-sheet was one with which they had every reason to be satisfied.

Dr. Hopkinson seconded the resolution to adopt the report and accounts, and the resolution was declared to have been carried unanimously.

A Shareholder thought that more particulars of the accounts should be shown, but accepted the explanation of the chairman that this would not be desirable in view of competition.

Mr. Harvey was re-elected as a director, and Messrs. Parkinson, Mather & Co. were re-elected auditors of the company.

In returning thanks for a resolution that the usual remuneration be given to the directors, the Chairman said that the directors had been very ably assisted by Mr. Grindle, the manager, and by all the officials of the company. In the past the directors had declared an interim dividend, and although they had power to do that under the articles of association, he would prefer that the shareholders should confirm the course they had taken.

Mr. Priestly seconded a resolution to this effect.

Mr. Harvey said that before the resolution was put he would like to remark that, considering the present price of materials and what could now be got for batteries as compared with the figures in the early days of the company, he thought there had been exceedingly good management. The company had now a very large amount of orders in hand, sufficient, at the present rate of output, to last for a very considerable time to come, and it would be therefore necessary to still further increase the works.

The resolution as to the dividend was then put to the meeting and carried.

Votes thanking the directors, manager, and staff were responded to by the Chairman, on behalf of the board, and by Mr. Grindle on behalf of himself and staff.

The Brush Electrical Engineering Company, Limited.

The directors' report to be submitted to the tenth annual general meeting to be held at Cannon Street Hotel, E.C., on Friday, September 8th, 1899, at two o'clock p.m., reads as follows:—

"The directors herewith submit the balance-sheet and profit and loss account for the year ended June 30th, 1899. The profit and loss account shows an available gross profit of £57,259 11s. 9d. After deducting maintenance, general charges, interest on debenture stock, and interim dividend on preference shares for the half-year ended December 31st last, there remains a balance of net profit of £26,480 7s. 3d. The directors recommend that this sum be applied as follows:—

	£	s.	d.
To dividend at the rate of 6 per cent. on preference shares for half-year ended June 30th, making 6 per cent. paid for the year	5,400	0	0
„ dividend at the rate of 5 per cent. on ordinary shares for the year	9,000	0	0
„ bonus payable to employés under profit-sharing scheme	1,980	0	0
„ depreciation reserve fund	5,000	0	0
„ balance carried forward	5,100	7	3
	£26,480	7	3

Capital expenditure to the extent of £55,956 2s. 6d. has been incurred during the year on extensions of buildings and plant at Loughborough, to enable the company to meet the growing demand for electric traction and power distribution undertakings in Great Britain and the Colonies. The provision referred to in last year's report with reference to the Workmen's Compensation Act has proved to be more than sufficient to meet the requirements of the case; and the directors propose that the company should continue to effect its own insurance in respect of the Act. The policy of developing the company's facilities for dealing with electric traction contracts has borne good fruit during the past year; and the works are well filled with orders for steam engines, electrical machinery, and rolling stock. The result of the year's trading enables a further distribution to be made to the company's employés under the profit-sharing scheme, with the results of which the directors continue to be satisfied. The directors have decided to make the company's financial year coincide in future with the calendar year. A balance-sheet and report will accordingly be issued for the six months ending December 31st next, and thereafter for each whole year ending December 31st. Mr. J. B. Braithwaite, jun., and Mr. B. H. Van Tromp are the directors who retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers & Co., also retire and offer themselves for re-election.

Prospectus.

The prospectus of the Electric Lighting and Traction Company of Australia, Limited, was before the public at the earlier part of the week, the list closing on Tuesday last. The Electric and General Investment Company offered, on behalf of the Brush Electrical Engineering Company, 20,000 6 per cent. preference shares of £5 each, at a premium of 10s., and 20,741 ordinary shares (£5) at par. In addition 1,400 ordinary shares are issued in part payment of purchase money, 7,859 ordinary shares being reserved to shareholders in the existing Melbourne companies, and these will also be issued as fully paid in part payment of the purchase price. The company, which has a nominal capital of £300,000, will carry on electricity supply business for lighting, traction, and other purposes in the Australian Colonies, which are believed to offer a large field for electrical development, and for the investment of capital therein. The undertakings of the New Australian Electric Company, Limited, and of

Digitized by Google

the A. U. Alcock Electric Light and Motive Power Company (both already supplying electricity in Melbourne and suburbs, and holding electric lighting orders in certain districts). Extended orders for additional works in the same districts are being applied for. The maximum charge per unit is 9d., but the companies are charging 7d., with discounts down to 5d. The population of the several districts is 216,000, and the price of gas is 5s. per 1,000. During the past four years the two companies have shown an average combined net annual profit of £8,831, exclusive of charges for interest and depreciation. The amalgamation of the two concerns can hardly fail to effect economies, as the two generating plants will be now brought into one set of buildings. The Melbourne City Council is purchasing the rights, plant, &c., of the two companies in the city district, paying therefor £40,000 in cash, but the companies will continue the supply of current until the municipal station is completed. It is not anticipated that the withdrawal of the city supply will reduce revenue, as the suburbs are to be energetically worked. The company will not confine itself to electric lighting, but is already proceeding with electric traction negotiations. There will be a local advisory board of directors at Melbourne, the home board consisting of Messrs. J. B. Braithwaite, jun., J. F. Albright, A. U. Alcock, M. F. Armstrong, and R. P. Sellon. Mr. F. W. Clements, M.I.E.E., is the engineer. Messrs. Kincaid, Waller & Manville being consulting engineers. The registered office is 49, Queen Victoria Street. The purchase price of the two undertakings is fixed at £179,105, and the way this is made up is shown in the prospectus, as are also particulars of contracts entered into, &c. We have often thought that our Australian Colonies offered a splendid field for electrical development and for the profitable employment of English capital. We shall probably see a good deal of this within the next few years.

Manchester Electrical Works.

THE *Financial Times* says that the following circular letter has been issued to the shareholders of the Manchester Electrical Works, Limited, by the secretary:—

"Dear Sir (or Madam),—I am instructed by the directors to send out the following letter as a reply to many inquiries received from shareholders.

"Since the circular of December 2nd, issued by the directors, the sum of £900, less charges, being the purchase price of the works by Mr. Thomas, as approved at the general meeting of September 5th, 1898, has been paid. A proportion of this has been absorbed by payment of rent, legal and other charges, rates, taxes, &c. No fees have been paid to the directors, and there are no charges for office expenditure. The balance of cash is at the bank. Securities were taken by the directors in connection with Mr. Rawson's liability to the company. These securities will require careful realisation, and it is hoped that the directors will be left a free hand in the matter, as they are acting in the interests of the shareholders only. Negotiations are pending for the sale of the company's rights in the Woodhouse & Rawson electric filaments, which are acknowledged to be the best in the market.

"The directors do not consider that any benefit would be derived from calling a meeting until they can report more definitely on the company's position. They will, however, not fail to keep the shareholders informed of any alteration which may occur."

TRAFFIC RECEIPTS.

The Blackpool and Fleetwood Tramroad Company.—The receipts for the week ending August 26th, 1899, were £2,090 6s. 11d.; receipts for week ending August 26th, 1898, £1,212 8s. 6d.; aggregate for half-year to date, £11,990 18s. 8d.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending August 25th, 1899, were £3,692 18s. 8d.; corresponding period 1898, £3,171 0s. 8d.; increase, £521 17s. 7d.

The City and South London Railway Company.—The receipts for the week ending August 27th, 1899, were £895; week ending August 28th, 1898, £866; increase, £29. Total receipts for half-year, 1899, £8,641; total receipts corresponding period, 1898, £8,695, decrease, £54. Miles open, 3½.

The Dover Corporation Electric Tramways.—The receipts for the week ending August 26th, 1899, were £346 16s. 6d.; week ending August 26th, 1898, £278 1s. 6d.; increase, £68 15s. Total receipts to date, 1899, £6,488 0s. 9d.; corresponding period, 1898, £5,357 9s. 9d.; increase, £1,130 11s. Miles of track open, 1899, 3; 1898, 3. Car miles run, 1899, 4,966; 1898, 4,339. Number of cars, 1899, 12; 1898, 10.

The Dublin United Tramways Company.—The receipts for the week ending Friday, August 25th, 1899, were as follows:—D. U. T. Co., horse cars, £2,525 8s. 9d.; ditto, electric cars, £1,469 12s.; D. S. D. Co., electric cars, £1 699 8s. 8d.; total, £5,693 19s. 5d. corresponding week last year—D. U. T. Co., horse cars, £3 020 14s. 11d.; ditto, electric cars, £523 5s. 4d.; D. S. D. Co., electric cars, £1,240 1s. 10d.; total, £4,784 2s 1d.; increase, £849 17s. 4d. Aggregate to date, £88 023 9s. 7d.; aggregate to date last year, £86,586 7s. 5d.; increase to date, £1,437 2s. 2d. Worked:—The mileage open is 18 miles electrically, 26 miles by horses, as against 12 miles electrically, and 30 miles by horses, for the corresponding period last year.

The Halifax Corporation Tramways. — The receipts for two weeks ending August 20th, 1899, were £1,671; Miles of track open, 12. Car miles run, 28,124. Number of cars, 21. The receipts for two weeks ending August 24th, 1898, were £648. Miles of track open, 8. Car miles run, 7,443. Number of cars, 10. Increase, £1,028. Total receipts to date, August 20th, 1899, from August 24th, 1898, £20,384. Total receipts to date, August 24th, 1898, from June 30th, 1898, £3,241. Increase, £18,143.

The Liverpool Overhead Railway Company.—The receipts for the week ending August 27th, 1899, amounted to £1,899; corresponding week last year £1,661; increase, £238.

The South Staffordshire Tramways Company.—The receipts for week ending August 18th, 1899, were £703 2s. 6d.; aggregate receipts for 34 weeks, £22,874 6s. 6d.; week ending August 19th, 1898, £700 8s. 2d.; aggregate receipts for 34 weeks, £21,289 5s. 6d.

STOCKS AND SHARES.

Wednesday Evening.

THE Transvaal trouble hangs like a sable cloud over the Stock Exchange, retarding enterprise in almost every direction, and causing grave anxiety in all the markets. Despite the huge amount of public money that awaits investment, the owners of the cash decline to use it freely in the Stock Exchange, owing to the political uncertainties of the moment. The electric lighting and kindred departments of the House would be among the first to benefit by a return of public confidence, but, as it is, there is so little business doing, that a change of price of any kind in a quotation is considered noteworthy. As one of the jobbers in the electrical supply section said to us the other day, "We tick the prices on the lists day after day just as a matter of form, and not because there is any need to do it." City of London, however, are 10s. better; Charing Cross and the other two West End companies sharing the same honourable distinction. Firmness is the prevailing feature, the tone throughout the list being very good. Citys still enjoy the attraction of being a good medium for speculation, and the account was arranged on Tuesday at an average rate of 5 to 7 per cent. for carrying over the shares. City of London 5 per cent. Debenture stock is being asked for, and the price has risen two points.

The telegraph market has naturally been agitated by the fears of a Transvaal rupture, to which reference has already been made. Prices of the Eastern Companies keep steady, but the dealers are naturally shy of making close prices, and suspended animation is the order of the market. Eastern Extension shares are stolidly unmoved at the effort which the company is making to improve its Australian business. The American Cable Company's stocks show very little alteration one way or the other. A temporary lull in the "Yankee boom" has resulted in a corresponding quietness of Anglo-American issues, speculators being anxious for a little more light upon their path before adopting aggressive tactics again. West Indian shares maintain their firm front, even in face of the news that is daily received as to the prospects of another hurricane in these islands.

Telephone descriptions are tame and featureless. Nationals at 5⅜, ex dividend, have ceased to attract attention, and the market is waiting for a new move on the part of the company or the Government before tinkering with the price. We might, by the way, suggest to the Stock Exchange managers that while the alterations to the House are in progress some better arrangement with regard to the telephonic service would be worth introducing. At present the Stock Exchange labours under an arrangement which, to the members, combines the maximum of inconvenience with the minimum of proper management.

Brush Electrics have lost part of the ground they gained last week, and the price has fallen to 2 middle. A few sales were made by people who had long given up hopes of ever seeing a rise in the shares, and who took advantage of the late advance to clear out of their holdings. There is a tendency to buy the senior securities of Electrical Supply and Traction Company, but this is retarded by the uneasy feeling that prevails amongst the investment markets generally. Crompton's Debentures have secured a point rise, and an advance of 2 was scored by Aluminium 4½ per cent. Debenture stock. Callender Cable shares retain their rise of last week, and a small premium is already established upon the new Preference shares offered by Henley's.

New issues are nearly as rare as snakes in Iceland, but the Electric Lighting and Traction Company of Australia has been boldly bidding for popular favour. We fancy its reception must have proved a little disappointing to its promoters, and no market for the shares has been made in the Stock Exchange. The company certainly appears to have some chance of success, but to face the music in the dog-days is a trying experience for any new concern, especially when the object is of a speculative character, and one which it requires some faith and enterprise to take up heartily.

The electric railway market presents no special mark of interest. Waterloo and City Ordinary has fallen 1, but the main spirit of the market in the Stock Exchange is out of town, and dealing is more or less a matter of negotiation. Central London shares were carried over at 10½, the rate of contango being 5 to 6 per cent.

Shareholders in the Manchester Electrical Works, Limited, are not likely to be particularly pleased with the circular just issued by the directors in response to a number of questions which have been addressed both to the company and the Stock Exchange. It would appear that the purchase price of the works has now been paid to the company, but we are not told how much of this now remains. The references to Mr. Rawson's liability to the company are vague, and we think a little more frankness would have been appreciated by the patient shareholders.

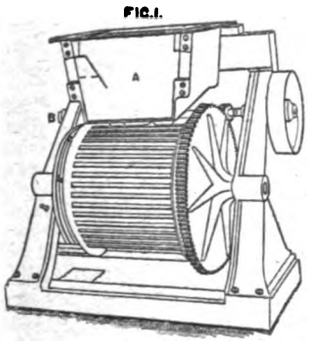
SOME FORMS OF MAGNETIC SEPARATORS, AND THEIR APPLICATION TO DIFFERENT ORES.*

By H. C. McNEILL, Assoc R.S.M.

The first application of magnetism as an agent for the separation of a magnetic from non-magnetic substances was probably the permanent hand magnet used in the machine shop for separating iron or steel turnings, &c., from brass or gun-metal sweepings. Similarly, foreign oats and grain are freed from bits of iron wire, pieces of cutter blades, nails, needles, &c. The railway companies and other large employers of horse labour have found it necessary to subject all the materials utilised for horse food, such as maize and oats, to rigorous mechanical and magnetic cleansing, for which purpose a permanently magnetised steel plate about 4 feet long, 6 inches wide, and ½ inch thick, with the long edges horizontal, is placed transversely, and inclined at an angle of about 35° to a continuous stream of grain fed from a hopper. An automatic scraper, in the form of a belt revolving round pulleys at each end of the magnet, and provided with a brush of leather, removes any accumulation every two minutes. This is pushed to the end of the magnet, and drops into a separate compartment; the grain which passes on is jigged on a three-bottomed perforated tray, by which means not only is the corn or maize separated, but the oats are freed from mixture of smaller seeds, bits of stone, and dust.

With the introduction and wider application of electro-magnetism, not only have machines been devised whereby naturally magnetic iron ores are freed from admixtures of other minerals, but by a preliminary roasting, *i.e.*, the artificial production of magnetic oxide of iron, other ores may be rendered suitable for a magnetic separation treatment. Mr. R. E. Commans mentions† that Sella, in Piedmont,

FIG. 1.



in 1855, was the first to use an electro-magnetic separator, but to free the magnets the current had to be broken; also that in 1881 Heberle, at the Friedrichssegen Mine on the Lahn, introduced a continuous current machine for separating blende from spathic iron ore after a preliminary roasting. In addition to the separator which bears his name, and which is dealt with in this paper, Mr. Heberle also designed that part of the dressing floors at the Gellivare Company's Works at Lulea, where the apatite, after being separated from the magnetic iron ore with which it occurs, has to be freed from a small percentage of hæmatite before being converted into soluble phosphate.

Other workers, both in Europe and America, including Wenström, Ball and Norton, Chase, Conkling, Hoffman, Kessler, Buchanan, King, Edison, and Wetherill, have all designed machines suitable to treat certain classes of ore which have come under their particular observation, and have successfully dealt with the problems presented by local conditions and peculiarities.

In the summer of 1898 the author had the opportunity of seeing some of the principal magnetic concentration plants in Sweden, and the present paper is mainly confined to these. He is indebted to the various managers of works, engineers, and others for the information freely accorded in every case.

The endeavour has been to present an outline of the machines and ore treatment processes. The sketches are entirely diagrammatic, and have been prepared from the author's hand sketches.

The machines will be described, in each case with the accessory ore treatment processes, in the following order:—

1. The Wenström machine.
2. The Monarch machine.
3. The Dalvik-Grödal machine.
4. The two types of Heberle machine.
5. The Wetherill machine.

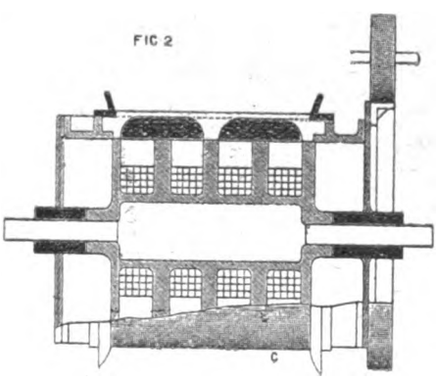
1. The Wenström Machine.

This is probably the simplest, and, for the particular purposes which it is intended to fulfil, the most efficient separator at present in use. Unlike most other designs, it is capable of treating ore of fairly large size, and it is not necessary that the stuff treated should be previously dried; its chief use is in such cases where the magnetite iron ore contains inclusions of rock, or where, as in open-cast workings, portions of the containing walls of the ore body get mixed with the ore in blasting and like operations. As a general rule, it is found to be more economical to pass the whole of this material collected together over a Wenström machine, after the "best" of a blast has been dealt with, than to attempt further hand selection in the quarry or underground. In addition, there are other uses to which this separator may be put, such as the treatment of cupola residues and foundry loam and sand; also the recovery of cast-iron shot entangled in blast furnace slag, &c.

Fig. 1 gives a general view of this machine. The material to be treated is fed through a hopper, A, and on to a jigging tray, which receives its motion from a cam arrangement placed on the shaft, B. This tray is inclined, and at each recoil a line of ore is left on the drum. Figs. 2 and 3 show part sections of the drum in directions at right angles to one another.

C is the armature barrel, consisting of a series of soft iron bars, each separated from the other by a bar of wood. D is a stationary field magnet, placed eccentrically with regard to the armature barrel. Non-magnetic end plates, carefully fitted with "jointing," so as to be water-tight, bind up the whole into the form of a drum. The bars of soft iron are internally shaped, so that each successive bar

FIG 2



becomes oppositely magnetised, a combination of greater power being thus exerted on a piece of ore large enough to bridge the distance between two adjacent bars.

The magnetic portion of the ore adheres to and is carried round on the drum until beyond the influence of the magnetic field, when it drops away down a shoot at E, whilst the non-magnetic portion passes down in front of the drum into a shoot at F.

A machine with a drum of 2 feet 2½ inches diameter and 2 feet length, revolving at 30 revolutions per minute, will treat about 5 tons of mixed material per hour. Such a machine is capable of dealing with ore of any size up to pieces that will pass through a screen of 4-inch mesh, and requires a current of 15 amperes, the tension at the dynamo terminals being 110 volts. Although the machine may be and is used on ore which is quite wet, the greatest efficiency is obtained when the material to be treated is dry, and in some cases, as

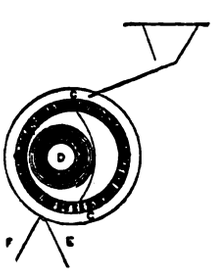


FIG. 3.

at Dannemora (Sweden), care is taken to treat only that ore which is fairly dry, without incurring the expense of artificial drying, whilst in other instances (Grängesberg and Grangen) the ore is treated directly after being washed, and whilst quite wet.

This separator requires but little care and attention when working, whilst the cost of maintenance is practically *nil*.

Generally the most efficient plants are also the simplest. The process usually consists of either a rough preliminary sizing by means of revolving or flat screens, with or without washing, followed by treatment on the separator, or the uncleaned ore may be passed on to the magnetic machine direct, and subsequently screened into different market sizes. At Dannemora the latter method is adopted, and I am indebted to Captain Hammershal for placing at my disposal the particulars given in the following short description of the plant used there.

The ore on arrival at surface is first subjected to a rough hand selection on sorting-floors conveniently arranged near the shaft. Between 50 per cent. and 60 per cent. of the total quantity of ore raised is rich enough to be taken direct to the furnaces. The remainder, which is of any size up to 2 inches diameter, is trammed from the sorting floors to the separation plant, or to the ore heaps,

* Read before the Iron and Steel Institute at Manchester, August, 1899.

† *Proceedings of the Institution of Civil Engineers*, Vol. cxvi., 1893, p. 63.

Digitized by Google

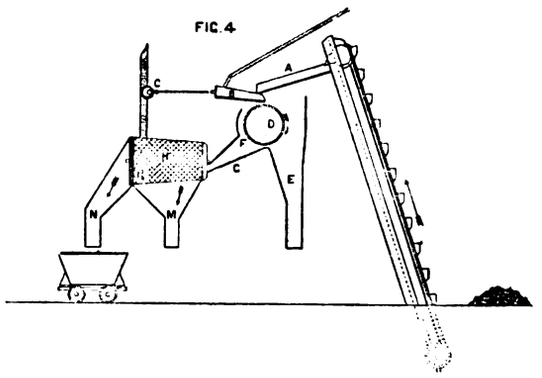
for future treatment by the separator. Fig. 4 represents the plant in use.

By means of the elevator shown, the ore is lifted and dropped on to the inclined shoot, A, and so on to the reciprocating table, B, which delivers it to the Wenström separator, D.

The tray, B, receives its motion by means of the small eccentric, C. The unmagnetic, and in this case worthless, portion falls at once down the shoot, E. The magnetic portion is carried round on the drum of the separator in the manner already described, and passes down shoot, G, into the revolving trommel or screen, H.

This trommel is of ½-inch steel plate, provided with ⅞-inch punched holes pitched 1⅜ inches apart, so that every body under ⅞ inch diameter passes through and down the shoot, M, the stuff above ⅞-inch, which

FIG. 4.

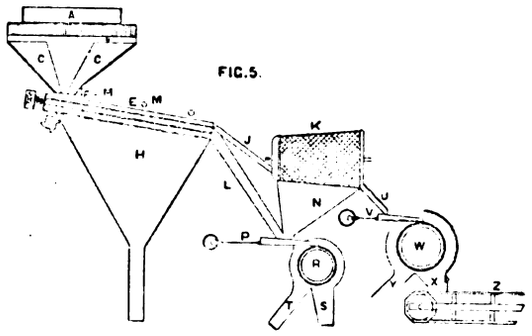


does not pass through the holes of the trommel, being delivered down the shoot, N, two marketable products being thus obtained.

An example where preliminary sizing and washing before separation is found to be advantageous is at Grängesberg (Sweden), and no doubt many of the members of this Institute will remember seeing the actual plant at work.

The mill is built at the foot of an embankment, so that the material to be treated is wheeled either in railway trucks or mine waggons directly into the top storey. During the winter, from obvious reasons, it is found impossible to run the mill; during this time large reserves of ore are accumulated. The railway trucks, when used, are so constructed that the whole sides are capable of being dropped, and rest horizontally on the top of grizzlies which extend from end to end of the truck. In figs. 5 and 6

FIG. 5.



the truck is represented at A and the grizzlies at B. The ore is shovelled by four to six men out of the truck on both sides, and that which is too large to pass through is hand-picked into the waggons, D, by men and boys standing on the platforms shown. The grizzlies are made of bars of iron, rectangular in section, and placed 5 inches apart, so that all the material under that size falls down the shoots, C C, and on to a three-bottomed perforated recoil table M. If small stuff has to be treated, it is dumped directly down the central shoot (fig. 6) from the mine waggons, which are run into the mill on the narrow-gauge rails shown and without being passed over the grizzlies. The three bottoms of the table are placed exactly above one another, and about 3½ to 4 inches apart, and are all actuated by means of the cam-shaft, cam, and springs. The top tray is provided with holes 1¼ inches diameter and 2 inches pitch; the middle tray has holes ⅞ inch diameter, and the bottom one ¼ inch diameter. The ore is distributed in an even layer by means of the hinged iron plate F, assisted by the vibrations given to the table, by which means it is gradually worked down the tray, and at the same is subjected to a thorough washing, the water for the latter purpose being supplied by the 3-inch perforated pipes, M M. The result is that all fine particles of ore are washed through the three trays down the shoot, H, and are carried off with the water by launders out of the mill, where boys are engaged in digging small channels, whereby the water very quickly drains away, leaving a coarse powder which is sufficiently rich to be marketable. The stuff under 1¼ inches and over ⅞ inch diameter passes through the holes in the top tray, and is caught by the middle tray; that which is less than ⅞ inch and more than ¼ inch diameter passes through the middle tray, and is caught by the third tray. Both sizes fall into the same shoot, L, and are treated on the smaller Wenström machine, B. The material between 1¼ inches and 5 inches, after being thoroughly washed, is delivered from the topmost tray into a shoot, J, and then into a revolving trommel K, also provided with 1¼-inches holes, and the ore which passes through these holes is taken by shoot N to join the products from the middle and lowest tray, and is treated by the separator, B. Stuff between 1¼ inches and 5 inches is delivered from the end of the trommel, K, on to the feed-plate of the larger separator, W. The material which comes away from the "worthless" shoot, X, is deposited on to a slowly-moving broad metallic belt, Z. Here any pieces of valuable ore are hand-picked off by boys and dropped into a shoot placed on either side of the belt, the worthless portion being left on the belt, and travels into a separate compartment. The use of the

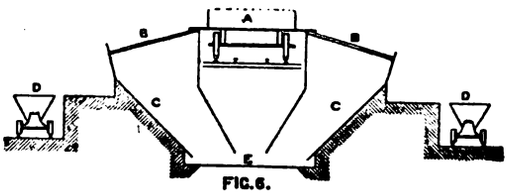


FIG. 6.

belt may be explained by the fact that the weight of some of the larger pieces of ore is greater than the magnetic force exerted by the machine, in which case they would fall off and get mixed with the worthless portion; also that it is more economical to adopt these means instead of hand-spalling and selecting the material to be treated according to more or less exact size. In addition, a lump of the stuff may be partly magnetite and partly unmagnetic, in which case, if the latter happened to come into contact with the drum first, it would not adhere.

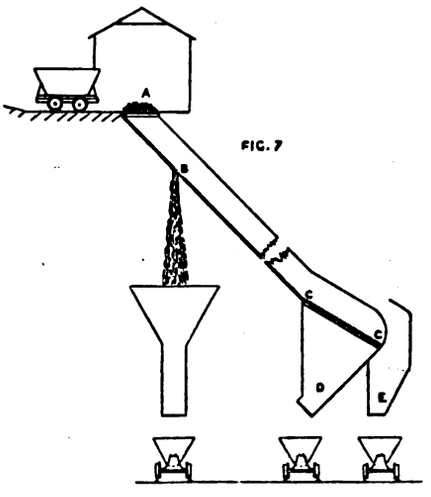
Three commercial products are obtained:—

(1) Ore between 1¼ inches and 5 inches diameter.
(2) Ore between 1¼ inches and ¼ inch diameter.
(3) Ore anything up to ¼ inch diameter.

The Grängesberg plant was designed to meet the particular requirements at the mine; the ore contains a considerable amount of specular iron, which somewhat easily crumbles, also hæmatite, and differs from that of Dannemora where the ore is compact and very hard, and there is little or no tendency to crumble, hence probably the difference in the methods of treatment and the primary washing, in order to save and eliminate the fine material.

At both Dannemora and Grängesberg the uncleaned ore averages 38 per cent. to 42 per cent., and the concentrates 58 per cent. to 62 per cent. metallic iron.

FIG. 7.



The rejected portion of the material consists of quartz, pegmatite (from inclusions and veins running through the magnetite ore bodies), schistose material, &c.

In both the preceding cases the operations of sizing or screening the ore are carried out mechanically either immediately before or after separation, but it may happen that the deposit is so situated as to render it necessary that the ore should be brought down to a convenient mill site, in which case the apparent disadvantages of position may be made use of in many ways. A case in point is at the Slotterberg Mine at Grangen. It appears that a considerable amount of work was done many years ago some 300 to 400 feet up the side of the hill, where large dumps were left by the old workers; in those days there were no magnetic separators, and only the very best picked ore was used; it is now found to be worth while to treat these old heaps. The stuff consists of anything between a powder and 6 inches diameter, and the whole of it, just as it comes to hand, is treated by screening, washing, sizing, &c., whilst on its way to the foot of the hill.

Digitized by Google

The first operation which the stuff undergoes is shown in fig. 7 at A, where the ore is dumped on to a screen at that point, and is spread out by boys with rakes, and as much of the finer material which adheres to the larger pieces sent through the screen; the latter, which has an area of one square yard, passes everything under 2½ inches diameter, the larger pieces remaining on the screen being hand-picked; after passing through the screen the ore falls down the wooden shoot, which is some 18 inches square in section and lined with iron plates, the whole roughly secured to trestles against the side of the hill, at about an angle of 45°. At B is a rectangular opening in the bottom of the shoot, 2 inches wide, which allows a quantity of the finer material to drop through, but which is skipped by larger pieces as they roll down. Arrived at the bottom of the shoot, the pieces of ore being thus fairly cleaned, fall on to another screen, C C, with which the shoot terminates, where a further separation of the smaller material takes place. This screen is 10 feet in length, and the bars are placed longitudinally and ½ inch apart; the material under ½-inch diameter passes through and is caught in the shoot D, the finer stuff so eliminated, together with that which drops through

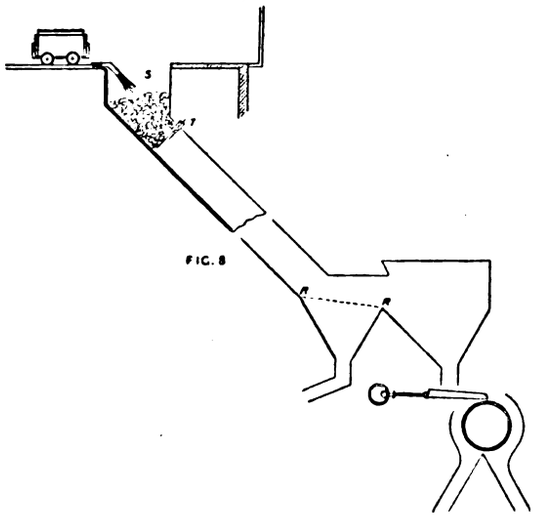


FIG. 8

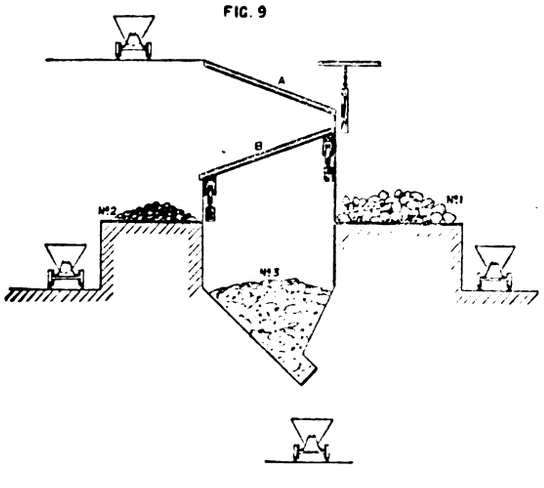
at B, is dumped near at hand as worthless; and the remainder, of size between 2½ inches and ½-inch, falls into shoot E; from this point it gravitates down an inclined tramway until it arrives at the top of another shoot or launder also placed against the side of the hill, and terminating in the separator plant (see fig. 8).

The product from shoot E is tipped from the waggon into a square chamber at the top of the launder, and is kept in place by a shutter or plate T by means of which the feed of ore down the launder may be regulated, after being washed by water from the hose pipe shown. The height of the ore chamber, S, is 60 feet above the separator, and on its way down the material is well washed. At B B is a fine screen through which passes the finer material still left, together with the water, the residue of washed ore passing on to the Wenström machine.

FIG. 9



In addition to the old dumps mentioned, good ore has recently been discovered near the base of the hill, which is possibly a continuation of the deposit worked, as already stated, higher up. The ore thus obtained is first screened close to where it is mined. Fig. 9 is a sketch of the plant used for this purpose. A is an inclined screen made of old railway metals with an effective opening of 5 inches between each; pieces above this size roll off the screen and form No. 1. Pieces under 5 inches pass through and are caught on screen B, also made of old rails, but placed 2½ inches apart, so that the material of size between 5 inches and 2½ inches falls to the sorting floor and forms No. 2. The ore under 2½ inches that passes through screen B forming No. 3.

No. 1 is hand-spalled, selected, and divided into

(*a*) Almost pure magnetite.
(*b*) Material containing 60 per cent. to 70 per cent. magnetite.
(*c*) Gangue with 12 per cent. to 15 per cent. magnetite.

(*a*) and (*b*) are sent direct to the furnace.
(*c*) is dumped as worthless.
No. 2 is similarly treated.
No. 3, after a further screening, is passed on to the separator.

The top screen may be extended to any length according to the amount of ore to be treated. The under screen, B, is usually a short piece mounted, as shown in fig. 9, on wheels, so that it may be moved under any part of the upper screen that it may be convenient to use. It is also a good plan to divide up the shed into compartments, so that when sufficient ore has been put through to be easily "looked over" by one man, the operation may go forward in another compartment; by these means also the workmen on the lower platform are protected from the falling ore.

(*To be continued.*)

THE STRESSES IN STEAM ENGINES, WITH SPECIAL REFERENCE TO ELECTRIC TRACTION.

One of the claims continually made for American engines is that they are so very heavy and substantial. Generally speaking, the American stationary engine appeals to the writer as being a well-designed, plain, substantial machine, but not in any respect superior in design to the ordinary English engine. How is it, then, that so much is heard about the great weight and substance of American engines, contrary to fact? Simply because everything American has been enormously strengthened during the past few years. A few years ago American machinery was usually held up as the embodiment of scamped material. Americans, not less offensive in their way, jeered at what they were pleased to term the sacrifice of material to British ignorance. However, time has wrought changes. Americans to-day claim that they sacrifice as much material as the most benighted Britisher, and having brought themselves to such an extreme will insist on counting it to themselves for righteousness, and the contrast with their former methods is so great that they really bring themselves to believe that such strength and substance were never before seen. Such, in brief, is the true history of the American belief of to-day, a belief which has no foundation so far as regards any superior design of the American engine. But they have succeeded in frightening some of our ignorant local politicians into the belief that the American traction experience, embodying as it does a long series of disasters and breakdowns of previously too light engines, has evolved a type of engine with which no English engine can compete. It is all a myth. Traction work requires strength, but not more strength than the ordinary good English modern high pressure practice allows. Let us examine the stresses in any engine under maximum load variation. We will assume the fly-wheel to be placed between the crank and its work in contradistinction to the faulty American practice of placing the fly-wheel on the opposite side from the generator.

Assume the engine to be a single crank engine under a full steady load. On each dead point of the crank full steam is admitted to the cylinder. At that point of the revolution there is absolutely no work passing from the crank-pin to the generator. Yet the generator is running under full current without a flicker of the meters. This work can have only one source, and that source is the fly-wheel. There is no other visible or conceivable source of energy. Obviously, therefore, there are two more or less short arcs of revolution during which the engine performs no work. If just before the dead point steam were shut off, the engine would do no work during the next half revolution; all work would come from the fly-wheel. When, after such a half revolution of no work, the crank arrives at its opposite dead point, it may or may not receive a full load of steam pressure. If it receive none, the engine will make another idle half revolution. If, however, steam be admitted, a working half revolution will be made and energy will pass into or past the fly-wheel, but is it not perfectly clear that so far as the stress in the crank and shaft is concerned there is no difference whether the previous stroke has been an idle or a working stroke? Every revolution sees the engine exposed alternately to full load and no load, and no matter how much the load on the generator may vary there can be no excess of stress brought upon the engine beyond the ordinary maximum stress of full boiler pressure, and an engine built for a given boiler pressure can never be put to stresses greater than those due to a steady load at this given boiler pressure carried to the latest point of cut-off. Under certain circumstances, the current output may be so very heavy as to bring an engine to rest in a very short time. In such a case of a load suddenly applied to swallow up the energy stored in a fly-wheel in the course of a very few revolutions, there may be very heavy stresses set up between the fly-wheel and the generator, and these stresses ought to be provided for. Unfortunately for the claims made as to traction stresses being so very severe, it is practically noticeable that American practice, as exemplified in many of the examples sent over to this country, takes so little account of these enormous stresses

Digitized by Google

as to place the crank-pin between the fly-wheel and the generator, and therefore exposed to all the variations of stress that ever occur.

When the load on an engine with correctly placed fly-wheel is varied from *nil* to maximum, the effect is simply to cause the fly-wheel to vary from, let us say, 101 to 99 revolutions on a normal 100 revolutions. This shows that the maximum possible load variation of this particular engine is such as to absorb in half a revolution 2 per cent. of the fly-wheel store of energy, and the governor varies its position to give full or minimum steam for the next half revolution. But, as an engine sets out its own duty one half a revolution at a time, it is obviously impossible for any load variation to throw upon any part of the engine a stress greater than that which takes place at every half revolution under a maximum steady load. Compared with marine work with a huge screw propeller flung alternately high in air and deep into water, the resistances due to the revolution of an armature in a medium resembling a fluid with a variable viscosity are mere trivialities. The sudden accession of resistance in the field of revolution cannot be compared with the material inertia of a mass of salt water. Catch phrases are very apt hooks on which to snare the unthinking, but it does not require much thought to perceive that the stresses in steam engines arise from boiler pressure, and that no matter how the load may vary it cannot induce the governor to do more than simply admit steam when the piston arrives at the end of the stroke. How such a process can cause huge stresses, beyond those ordinarily provided for, it passes common sense to perceive! Certainly it is possible that the many failures of high speed electric light engines have had their influence in giving to all electrical work a terrifying aspect. But it has been already pointed out in these columns that the one cause of the failure of so many high speed single acting engines has been the intolerable weakness of their crankshafts, such engines often demanding shafts fully sixfold the torsional strength of the shaft of a double acting engine of equal speed and power. As pointed out in the Electrical Review of last week, English practice in electric lighting has long been superior to the prevailing American practice, and there is no reason whatever for doubting the possibility of vastly improving on American traction practice. There is more of it in America it is true, but English practice already passes American in its general features and careful execution, and America has no monopoly of suitable engines. Abnormal stress is a bogey that has been made very useful, but it is high time that clear and truthful conceptions should be gained on so important a subject.

To give fixity of ideas, let an engine of 160 H.P. be assumed at 240 revolutions per minute, with a fly-wheel equivalent to a rim of 4,000 lbs., at a velocity of 80 feet per second. Then, in each stroke of the engine, there is developed 11,000 foot-pounds of work. The stored energy in the fly-wheel represents 400,000 foot-pounds, of which 3 per cent. approximately represents the regular addition of energy per stroke, and should measure the variation of velocity in one stroke under maximum load variation. The engine would then run about 4½ seconds under full load, and no steam.

The speed variation of an engine under maximum load variation is thus strictly a function of the fly-wheel. The sudden addition of load early in a stroke will at once check the fly-wheel velocity, and bring into action the inertia governor and thereby prolong the steam admission. It would approximate a late steam admission. At worst a load variation can only endure one stroke before it is met by the countervailing action of the governors, and in the above engine this is one-eighth part of a second. The speed variation between full and no load is a function of the internal energy of the governor itself—its general sensitiveness. This is simply determined by natural laws. These laws are well known, they are not the monopoly of any climate, or any maker, or any nationality, though it would appear as though there had been an attempt to corner them to uphold untenable claims. The easiest engines to govern are those of highest rotative speed, and as high rotative speed is more particularly English practice, the claims made elsewhere may well be doubted, unless sustained by physical laws. In the Glasgow engines, so much to the fore at the moment, the rim velocity per second is probably about 75 feet per second at most, referred to the whole wheel. The stored energy is thus barely 20 million foot lbs. At 5,000 H.P., the work per half revolution will be fully 1 million foot lbs., and the ratio to the fly-wheel energy will vary according to the relative positions chosen for the cranks.

Finally, one point more as to the enormous stresses due to traction. The effect of a suddenly applied load of 100 H.P. is at most equal to a steady stress of 200 H.P., and for this the shaft between generator and fly-wheel must be designed. A traction generator has no mechanical or material inertia to overcome when a sudden accession of load is put upon it, and this fact limits the maximum possible stress in the shaft to double the ordinary. Now, all crankshafts are designed in view of the fact that they receive a torsion from the crank which varies in a single crank engine from *nil* to a maximum of considerably above the mean torsion. After all, therefore, the difference of shaft diameter in any engine, before and after the fly-wheel, is not necessarily enormous. Allowing as much as 50 per cent. excess stress, a 24-inch shaft would become 27 inches beyond the fly-wheel, a 12-inch hole being assumed through the whole, or

$$D = \sqrt[3]{[1.5\,(d^3 - d_1^3)] + d_1^3}.$$

The dimensions given for the Glasgow engines are open to severe criticism, as is also the design of the shaft as a tapering structure.

Award.—The Cape Asbestos Company, Limited, has been awarded a gold medal and diploma of merit at the Greater Britain Exhibition, West Australian Section, Earl's Court, for their exhibits in blue asbestos removable coverings for boilers, steam pipes, &c.

THE INSTALLATION OF STEAM BOILERS.

VI.

For many years the furnaces of a Lancashire boiler were probably its weakest part. They were lap riveted both longitudinally and circumferentially, and each ring of the furnace tube was often very far from truly circular. The introduction of the butt joint for the longitudinal seams was a great improvement, but even with this improvement furnace tubes were not strong against collapse. It was found, in course of time, that short tubes were much less liable to collapse than were long tubes. Even the ordinary ring seams were a source of strength. Tubes were then stiffened by the use of rings of ⊥ iron (fig. 15) used as joint rings

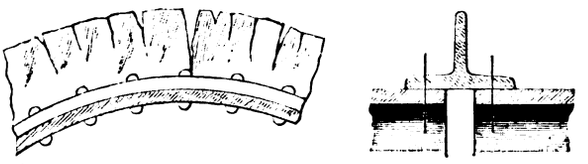


Fig. 15.

between adjacent rings of plate. The fault of the tee iron is that the part riveted to the plates becomes hotter than the web which projects into the water, and, in expanding while the web remains cooler, it causes the web to split. This fault was remedied in the Bowling hoop (fig. 16), which was

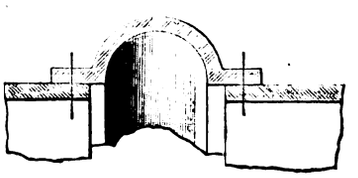

Fig. 16.

also supposed to act after the manner of a concertina and give elasticity endwise. It did not do so, but nevertheless, the Bowling hoop was an improvement, and gave anti-collapsive resistance. In the case of old boilers, it became customary to rivet rings of angle iron round the furnaces for purposes of strength. At first they were closely attached to the plates, but troubles of overheating arose, and rings became split, just as in the case of the T rings of fig. 15. The best system of attaching these stiffening rings is that of fig. 17. The ring was attached by wedges around the

Fig. 17.

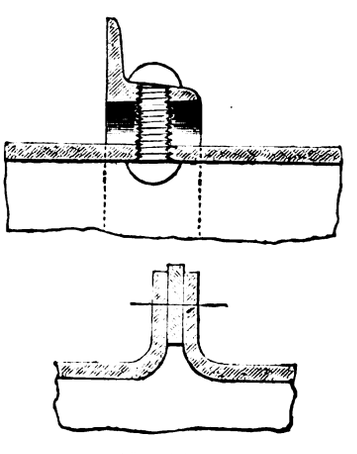

Fig. 18.

furnace tube, and holes were drilled through both ring and plate. These holes were tapped and a screwed bolt was tightly screwed into the two and riveted over on the water side. The whole of the ring was thus of one temperature, the space between the ring and furnace plate being an inch. But nearly all new boilers, 20 years ago, were already con-

Digitized by Google

structed with the Adamson flanged seam. In all other seams and rings there are rivet heads exposed in the furnace, edges of plates were also exposed, and in process of time such edges often became split and burned. They began to leak, and required frequent attention and repair. The flanged seam of Adamson, fig. 18, cured all these faults and had little to condemn it, has held its own to the present day, and appears likely to do so, for it seems to give to a furnace tube all necessary strength against the highest pressures, and it is the favourite seam in competition with the corrugated and the ribbed plates of more recent introduction. In the flanged seam there is neither head of rivet nor edge of plate in the furnace, and the flanging together with the flat ring between the flanges gives great rigidity, and also there is some longitudinal elasticity secured, which, however, is very trifling. In the most approved modern construction the rings of tube are first welded up solid and truly circular. They are then heated and flanged, a process which puts to proof the soundness or otherwise of the welding. They are then turned on the edge and face and put together by machine riveting with a turned joint ring. So constructed a furnace tube is a good and true mechanical piece of work. It deviates a mere fraction from strict circularity, and is as strong as any part of a boiler. The rings of plate which come next to the boiler end plates are often made stouter than the remainder, the better to withstand the severer stress which comes upon them at the attachment flange of the end plates. The ring next the back end plate is usually about 6 inches smaller in diameter than the rest of the tube, to which it is joined by a tapering length. In this way the back end plate is permitted to be attached by an inside flange to the shell and still preserve sufficient elasticity. The gusset attachments are also enabled to be sufficient and proportionate, and finally space is left between the two tubes to admit of a man passing between them into the lower part of the boiler. We need scarcely discuss the attachment of cross water pipes in the tubes. These are sometimes flanged and riveted, and sometimes are welded in. In either case recent practice has come more and more into line with our frequent condemnation of these useless encumbrances. Experiment has shown that they do not add to efficiency, and they do not aid circulation either, nor can it well be urged that they add to the strength of a furnace tube, of which the weakest part, namely, the furnace, is the one part, in which not even the advocates of tubes will advise them to be fixed. Further, they tend greatly to cause smoke, and check proper combustion, and they make a boiler very sooty on the one hand, while, on the other, they prevent proper access for the sweep and for the inspector, as well as increasing many times the need for inspection.

These pipes are often specified owing to some lingering belief in their efficacy, but it is difficult to discover how any engineer of experience should continue to prescribe these simply weight-producing impedimenta. Even boiler makers, who profit, we may presume, by the sale of such tubes, have begun to look askance at them, and to shirk putting them in even where originally specified. Our drawing of the boiler end plate shows how the furnace tubes are arranged upon these end plates in relation to the centre lines of the boiler. We have already pointed out that the space left between the connecting rivets of the tubes to the end plates and the lowest rivets of the angle iron attachments of the gusset stays must be 10 inches, a figure that seems to give fair results and one that has been attained by a long series of practical experiments. A suitable diameter for the furnaces of a Lancashire boiler seems to be two-fifths of the shell diameter. This allows fair room for cleaning between shell and furnaces and keeps the flanged seams clear of the shell sides. In order that the flanged seams of the two furnace tubes may not touch, it is arranged that the front end ring of one tube is 6 inches longer than that of the other tube, and conversely at the back end the final rings differ in length by 6 inches. The corresponding seams of the two tubes are thus 6 inches apart throughout. As regards strength against collapse the Board of Trade rule for Adamson flanged seams is

$$\text{Working pressure} = \frac{8{,}800 \times T}{3 \times D} \times \left(5 - \frac{L + 12}{67{\cdot}5 \times T}\right),$$

where T is the thickness in inches, L is the pitch centre to centre of the flanged seams, and D is the external diameter of the furnace. This rule supposes steel of an ultimate tensile strength of 26 to 30 tons. For a 40-inch diameter furnace ½ inch thick and 23 inches pitch the rule gives a working pressure of 132·5 lbs. per square inch. Lloyd's rule is much simpler, the working pressure being $\frac{1{,}000 \times (T - 2)}{D}$, where D is the external diameter in inches, and T is the thickness in sixteenths of an inch.

The furnace just named would show 150 lbs. working pressure by Lloyd's rule. The variety of satisfactory furnaces is so great, including the plain corrugated, Purves' ribbed plates, Morrison's suspension ribs, that a full discussion of the subject would occupy too much space. The different rules may be found in works on boilers or in the abstracts of Board of Trade and Lloyd's rules which are given in Kempe's Year Book. We need not discuss furnaces with plain joints. No modern boiler is now made for good work with anything less strong than the Adamson flanged seam. We may add, however, that the resistance to collapse increases with increase of tensile strength of the steel used, and this fact is something of a temptation to secure strength too dearly. The Leeds Forge Company advise, we believe, that steel for furnaces ought not to exceed 27 tons tenacity, though others have admitted 28 and 30 tons. The Germans who made the Fox furnace, in Germany, stated at one time that no trouble had arisen from 16,000 furnaces made from steel of 23 to 26 tons, but the 500 they had made from steel of high tensile strength had given more trouble than the previous 16,000 furnaces.

Experience generally points to the superiority of milder steel for furnaces. There is practically no cracking or splitting of any kind with this material. We need hardly say that, as with boiler shells, no fittings must be attached by bolts to the furnaces. Practically, the only things to be attached are the small angle iron lugs which carry the fire-bar bearers. These lugs should be attached by two rivets each, and it is an argument in favour of bars made in two lengths, that the weight of the grate and fire can thereby be distributed better than where long bars, supported only at the two ends, are used. In this case, however, the weight can be carried at the back end of the bridge casting, and we think that, with short bars partially carried at the centre, the supporting lugs may with advantage be tied across the furnace to each other by a flat stay to resist any possible spreading pressure due to the weight. So far we have spoken only of plain Lancashire boilers with circular flues throughout. For high pressures we consider the circular flue essential. Any departure from circularity can only be counteracted by the use of water pipes as struts to resist the inevitable collapse which would otherwise occur. Lancashire boilers are, however, sometimes made in which the back ends of the furnace tubes are replaced by numerous small tubes. While in themselves safe, they prevent entrance to the flues through the furnace, and they do not form so reliable a stay between the end plates as do the plain tubes, and they are less to be commended for bituminous fuel than for coke or other smokeless fuel, for which they should be efficient in adding to the heating surface. With these tubes it also becomes necessary to afford a stay or suspension to the furnace tubes from the shell in order to prevent too severe a stress on the ends of the small tubes and probable leakage. Some of the small tubes should also be nutted stay tubes, and the longitudinal bolt stays, usually omitted now from Lancashire boilers, should be retained as a safeguard. Numerous modifications of the Lancashire boiler have from time to time been made and patented, but it is safe to say that very few possess serious merit, many are absolutely dangerous, others are unscientific, and practically all cease to possess such merits as may be apparent at a low pressure when put to the stress of modern high pressures, which demand first either perfection of form or simplicity of staying such forms as are not self-supporting.

Gas.—There was a failure in the gas supply at Helensburgh, near Glasgow, at a busy hour on Saturday night, the place being plunged into darkness owing to water getting into a valve at the gasworks.

INTERNATIONAL CONGRESS OF TELEGRAPHISTS.

RESULT OF PROFESSIONAL COMPETITION.

THE jury have at length published their report on this competition, and we are able to give the details for the first time in English. For the Hughes apparatus the test was the transmission of 1,000 words in French, Italian, English, and German. The languages were equally divided. In addition, 200 groups of figures, not exceeding six figures to the group, and 100 words taken from a commercial dictionary, were sent. The times, &c., of the first nine competitors were as follows :—

HUGHES.

No.	Competitors.	Time employed in transmission.	Surplus of time resulting from errors.	Total time.	Prize obtained.
		M. S.	M. S.	M. S.	
1.	Grueber, Joseph (Munich)	32 38	Zero.	32 38	First.
2.	Cappanera, Giuseppe (Rome)	33 45	0 15	34 0	Second.
3.	Blein, Francois (Lyons) ...	34 29	0 15	34 44	Third.
4.	Käess, Otto (Munich) ...	34 20	1 0	35 20	Fourth.
5.	Michel, Fritz (Berne) ...	35 19	1 15	36 34	Fifth.
6.	Di Palma, Enrico (Naples)	36 24	0 15	36 39	Sixth.
7.	Ristori, Federico (Rome)...	36 35	0 45	37 20	Hon. mention.
8.	Mantone, Pasquale (Bari)	36 38	0 45	37 23	" "
9.	Geronimi, Luigi E. (Milan)	35 52	2 15	38 7	" "

The Morse test was divided into two parts, viz., transmission and reception. For the receiving test, 650 words were sent by means of a Wheatstone automatic transmitter working with a single current to a Morse receiver so arranged that the reception could be by sound or slip. For the sending test a like number of words were sent by the competitor. For each error not corrected, 20 seconds were added to the total time. The times, &c., of the first nine competitors were as follows :—

MORSE.

No.	Competitors.	Time employed in transmission.	Surplus of time resulting from errors.	Time employed in reception.	Surplus of time resulting from errors.	Total time.	Prize obtained.
		M. S.	M. S.	M. S.	M. S.	M. S	
1	Geronimi, Luigi E. (Milan)	20 10	zero	20 52	1 40	42 42	First.

9	Perego, Arturo (Mediterranean Railway)	23 21	0 20	24 25	10 0	58 6	"

The prizes were in two series of equal value, one series for either system. The following is a list of the series :—

1. A gold medal given by the Minister of Posts and Telegraphs, an artistic object given by the Organising Committee, and a diploma.
2. A silver medal given by the Minister of Posts and Telegraphs, an *objet d'art* given by the Organising Committee, and a diploma.
3. A silver medal given by the Minister of Posts and Telegraphs of Italy, an *objet d'art* given by the Organising Committee, and a diploma.
4. A silver gilt medal given by the Committee of Organisation, and a diploma.
5. A bronze medal given by the Organising Committee, and a diploma.
6. A bronze medal, and a diploma.
7, 8, and 9. Honourable mentions.

SOME NOTES ON THE ELECTRICAL MACHINERY AT THE COMO EXHIBITION.

BY KENELM EDGCUMBE, Assoc.M.INST.C.E.

(*Concluded from page* 310.)

COMING now to the electrolytic apparatus itself, the latest type is shown in fig. 12. As will be seen, each of the two gases is collected in a separate chamber. Fig. 13 shows a

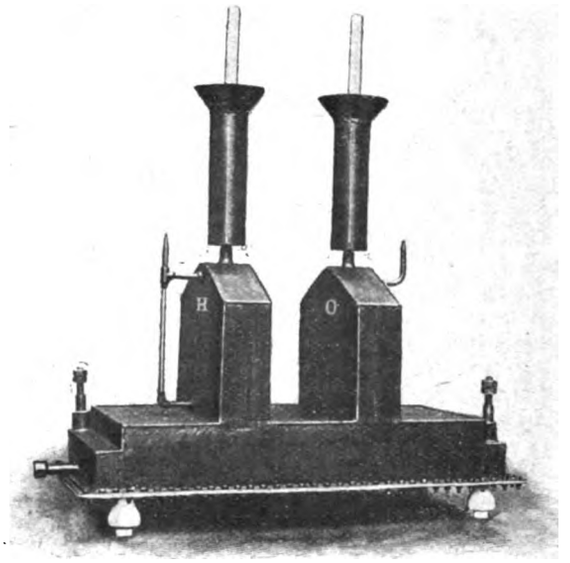

FIG. 12.

section through one of these, though of a slightly modified type. The electrodes consist of plates of sheet-iron, the anodes and cathodes alternating with one another and being connected in parallel. The distance from one plate to the next ranges from 10 to 12 mm. As will be seen from fig. 13, each electrode is in a separate compartment, also formed of sheet-iron, and perforated with 1 mm. holes to allow of the free passage of the electrolyte. These partitions are shown at E. All the compartments containing anodes communicate with the reservoir, G, by means of the small holes, F. From here the oxygen is led off through a tube (the junction being water sealed) to the gasometer. The hydrogen is in the same way led from the cathode compartments to its gasometer. *b* shows the positive terminal, the current entering the chamber at B. As will be seen, the whole apparatus rests on wooden blocks in the vessel, A, and in this respect differs from that shown in fig. 12, which is entirely self-contained. The chief feature about this apparatus is the use of metallic diaphragms. The advantages gained are, firstly, longer life, and secondly, greatly reduced resistance, owing to the large holes employed. The diaphragms, of course, do not form part of the electric circuit, as, in order to do so, they would require an additional voltage equal to that necessary for the electrolysis of water. In spite of

Digitized by Google

the large holes which are employed in the diaphragms, the separation of the gases is found to be very perfect, the hydrogen containing about 1 per cent. of oxygen, and the oxygen from 2 to 3 per cent. of hydrogen. The electrolyte employed is a solution of caustic soda of 25° Beaumé. The voltage required in all cases is only 2·2 at 77° F., or 1·8 volts at 165° F. The apparatus shown in fig. 12 takes 400 amperes at a current density of ·13 ampere per square inch. The total weight is 200 lbs., and the output per 24 hours amounts

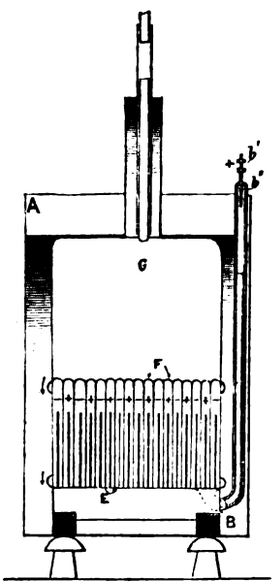

Fig. 13.

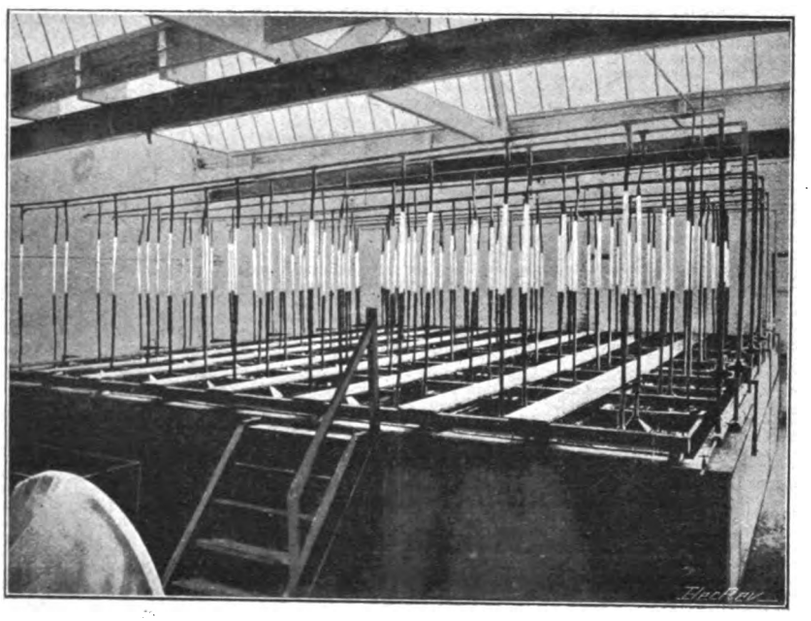

Fig. 14.

to 59 cubic feet of oxygen, and 118 cubic feet of hydrogen. The energy required is thus 400 × 2·2 × 24 = 21·12 units, or ·358 unit per cubic foot of oxygen.

Fig. 14 shows a large plant belonging to the Soc. Anon. Oxhydrique, of Brussels. This company retails the compressed gases at the following prices:—Oxygen, 8 francs per cubic metre, and hydrogen at 3 francs per cubic metre. In Italy, also, the War Department have lately laid down an electrolytic plant for the production of hydrogen for filling military balloons.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1899.

Compiled expressly for this journal by W. P. Thompson & Co., Electrical Patent Agents, 322, High Holborn, London, W.C., and at Liverpool, Manchester and Birmingham, to whom all inquiries should be addressed.

16,461. "Improvements in or connected with overhead collectors for electric railway vehicles." H. H. Hall and R. J. Urquhart. Dated August 14th.

16,492. "Improvements in or relating to apparatus for the suspension of wire cables and the like." E. Bennett. Dated August 14th.

16,494. "Improvements in or relating to automatic cut-off devices principally designed for controlling the flow of fluids and electric currents." H. L. Groome. Dated August 14th. (Complete.)

16,548. "Improvements in rails for electric trams, railways, and for other similar suitable purposes." W. Buck, T. L. Patchett, and B. W. Shaw. Dated August 15th.

16,555. "Improvements in the reduction of aluminium by electrolysis." F. A. Gooch. Dated August 15th. (Complete.)

16,569. "Improvements in accumulator electrodes." R. A. Katz. Dated August 15th.

16,584. "An electric light or lamp." H. L. Arnold and J. W. Graydon. Dated August 15th.

16,600. "Improvements in the manufacture of earthenware troughs for carrying electric cables and analogous purposes." G. H. Nisbett. Dated August 16th.

16,627. "Improvements in electric arc lamps." J. Lesthevenon. Dated August 16th. (Complete.)

16,628. "Improvements in arc lamps." J. D. F. Andrews. Dated August 16th.

16,629. "Improvements in electric signs or signals." J. D. F. Andrews. Dated August 16th.

16,636. "Improvements in electrical accumulator batteries." Dated August 16th. (Complete.)

16,648. "Improvements in holders for the shades of incandescent electric lamps." R. J. Liebisch. Dated August 16th.

16,650. "Improvements in conduits suitable for electric mains." S. Petersen. Dated August 16th.

16,690. "A new or improved composition for use as an electrolyte in batteries or cells." J. Byrant. Dated August 17th.

16,739. "Improved contact system for electrical railways." W. Grunow, jun. Dated August 17th (Complete.)

16,743. "Improvements in holders for incandescent electric lamps and shades." R. J. Liebisch. Dated August 17th.

16,749. "Improvements in incandescent electric lamps." J. R. Schauer. Dated August 17th.

16,796. "Improvements in or relating to conduits for underground electric cables, telephone, or telegraph wires, or for conveying fluids." G. H. Cullen. Dated August 18th.

16,830. "Electrically-controlled design reading apparatus." B. J. B. Mills. (L. David and T. David, France.) Dated August 18th.

16,824. "Improvements in apparatus for electro-chemical and electro-thermic melting operations especially for the production of calcium carbide." E. Grauer. Dated August 18th.

16,835. "Electric loopup." G. Tarry. Dated August 19th.

16,854. "Improvements in connection fittings for various electrical purposes." R. F. Hall. Dated August 19th.

16,859. "Safety guard for trolley rope on electric trams or other motors." J. Costigan. Dated August 19th.

16,878. "Telephonic apparatus for transmitting and receiving messages simultaneously to and from several distant stations." Siemens, Bros. & Co., Limited. (Siemens & Halske, Actien Gesellschaft, Germany.) Dated August 19th. (Complete.)

16,879. "Method for dividing an alternating current into two currents whose phases are shifted relatively to each other through a determined angle." Siemens Bros. & Co., Limited (Siemens & Halske, Actien Gesellschaft, Germany.) Dated August 19th. (Complete.)

16,889. "Improvements in electrical transformers." A. F. Berry. Dated August 19th.

16,898. "Improvements in pneumatic controlling mechanism for electric railway cars." S. H. Short. Dated August 19th. (Complete.)

ELECTRICAL PATENTS OF 1885 EXPIRING IN SEPTEMBER, 1899.

We are informed by W. P. Thompson & Co., that about 60 applications for electrical patents were filed in September, 1885, of these some were never completed, and of those that were only one has been maintained to run its full term, viz., 14 years, and being of considerable interest we give a short abstract of it below:—

10,451. "Improvements in the manufacture of metal pans, cylinders, boilers, containers, or receptacles." F. E. Elmore. Dated September 3rd, 1885. Boiling pans, pans, cylinders, hollow-ware, &c., are produced by the electro-deposition of a metal, generally copper, upon suitable moulds, as described in specifications Nos. 1,737, 4,499, and 8,707, A.D. 1885. The mould is prepared by coating it first with a film of adhesive and then a film of non-adhesive copper; it is then mounted on the shaft and immersed in the bath. The mould is then connected with the negative pole of a dynamo or other source of electricity, the positive pole being connected to strips of copper, or of carbon, lead, or other insoluble substance; the strips follow the form of the mould as nearly as possible, and are all placed at the same direction from the shaft. The shaft is rotated during the deposition by toothed or belt gearing, the surface of the metal being at the same time acted upon by a burnisher. 2 claims.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson and Co., 322, High Holborn, W.C., and at Liverpool, Manchester, and Birmingham, price, post free, 9d. (in stamps).

1897.

15,169. "A method of measuring electrical power and appliances for that purpose." M. S. Field. Dated June 24th, 1897. Relates to energy meters and electro-meters. Power supplied by an alternating current to any circuit is

Digitized by Google

measured by the reading of two instruments indicating $(1\ c\ v)^2$, and $(c\ v)^2$ respectively, where c and v are simultaneous, instantaneous values of the current and pressure. In a modification, the second instrument indicates $(v\ c)^2$; in three other modifications the instruments indicate v^2, c^2, and either $(c\ v)^2$ $(c\ v)^2$ or $(v\ c)^2$ from differences of which the power v c may be obtained. A single differential instrument may be used, indicating power directly. The supply mains are connected by the primary of a transformer, and one main continues a low fixed resistance. The transformer has two equal low-pressure secondaries connected through the two circuits of a differential current meter to the ends of the resistance. For the first modified method, the resistance is in two equal halves and the transformer has a single secondary, or is replaced by a single coil, a part of which serves as a secondary. With a single resistance, secondary, and instrument a switch may be used to reverse connections so that the two quantities may be observed successively. With two instruments a switch may be used to change the connections so that they indicate current and pressure separately; from these and the power readings the apparent power supplied, and phase difference may be obtained. Power supplied in any three-wire system is obtained by making separate measurements between each outside main and the third one, or a single instrument may be used. The instruments are preferably hot-wire or electrostatic. The movable part is connected to the central main, and carries plates within two pairs of fixed cells, which are connected separately to the terminals of fixed resistances in the outer mains. Such an instrument may be used on a two-wire system. A differential instrument may be made with two hot wires or other devices acting oppositely through two pulleys and cords on one indicator. Two distinct instruments may be mounted in one case, with pointers indicating on one scale. To fix the pointers while their positions are observed, two strips of peper are pressed against them by shafts which are cranked and connected by a link to a handle.

15,237. "Improvements in electrical switch apparatus for the points and crossings of electrical railways or tramways with underground conductors." Siemens Bros. & Co., Limited. (Siemens & Halske.) Dated June 25th, 1897. Relates to switches for the rails and conductors of electric railways and tramways on the conduit system. Conductors, permanent way. The point of the rail is pivoted, and the point of the conductor is pivoted so that it has a greater angular throw as the two are connected so as to move simultaneously by the insulating piece. The end of the conductor point is insulated by a part, and short lengths of the conductors alongside are also insulated, the lengths of the portions being greater than a part, so that any sparking may occur at the part rather than at the point of the conductor. The electric connections on a cross-over road cause a change of polarity as the car passes over the points. 3 claims.

15,169. "Improvements in arc lamps." P. Duffee. Dated June 24th, 1897. Relates to arc lamps.—A ratchet escapement lamp is constructed. The upper carbon of which is carried by an insulated holder on a frame which slides in tubes and may be provided with anti-friction rollers. Connection with it is effected by a flexible conductor. The lighter, lower carbon holder is attached to a rod, within the tube, and connected through the frame. The holders are hung by a chain or cord from a pulley attached to a toothed wheel, and supported in fixed bearings. A frame, movable about the same axis, carries a pinion in gear with the wheel and attached to a ratchet wheel with deep teeth. This is normally held in engagement with a stop by a link connecting the frame with a weighted or spring actuated lever. A curved iron plate forming part of the lever enters a shunt solenoid which turns the frame and the wheel when the ratchet is in engagement with the stop and the terminal difference of potentials sufficient, thus bringing the carbons together until the ratchet leaves the stop. The ratchet may be attached to a heavy fly-wheel to check its rotation when released. 2 claims.

15,329. "Improvements in apparatus for operating two or more electric current switches simultaneously or periodically." C. D. Lucas. Dated June 26th, 1897. Relates to operating mechanism for resistance and other electric switches when employed for making and breaking signal or other electric currents in predetermined order, such as those applied to illuminated signs and other signalling and switching devices. A section of the apparatus is shown in which a row of switches is provided with levers. Each lever is provided with a guide swell, an oblique recess and a groove in the end. The levers are operated to close or open the switches by the motion of the levers, which are connected by a link and have controlling springs. The levers have operating studs or rods for engaging with the levers. A selecting device, consisting of a slotted rotating disc is operated by a ratchet mechanism or hand lever. Lifting rods are provided with projections which pass through or are depressed by the disc. The other ends of the lever allow the levers to be in their operative position or to be raised to the inoperative position. The mechanism may be operated by a motor or by hand, and indicators may be employed with the switches. 4 claims.

15,399. "Improvements in or relating to carbons for electric welding, brazing, and the like purposes." G. W. de Tunzelmann. Dated June 28th, 1897. A metallic oxide or oxides, such as the oxides of iron, copper, lead, or manganese, are incorporated or mixed with the carbon to form the electrodes or carbons for use for electric welding, brazing, and like purposes. The object is to reduce the excess of free carbon in the arc, and also to produce an arc in which the heat is more equally diffused owing to the presence of a metallic vapour. 1 claim.

15,411. "Improved electric igniter for gas engines." R. Bosch. Dated June 28th, 1897. Relates to a dynamo for generating an electric current for igniting in gas engines. The armature is stationary, and its insulated terminal can be rigidly attached to the conducting-wire or to a terminal on the framing. Magnets with or without sole-plates embrace the armature, and between them soft-iron strips are mounted and oscillate being attached to the end discs on the shaft. 2 claims.

15,419. "Improvements in or connected with electrical distribution fuseboards." Veritys, Limited, and M. B. Cotterell. Dated June 29th, 1897. A main lead is connected to several screw terminals so that the fuses are in each branch. Each fuse is held by means of C springs and clamping nuts. Projections and recesses may be employed on the springs and nuts to produce a locking action. The fuses are supported on porcelain troughs separated by glass washers, and carried by rods threaded through holes in the blocks and washers. The rods are coned at one end, and have extra locking-nuts to hold the bars rigidly in place across the iron case. 5 claims.

15,472. "Improvements in electric furnaces and processes of treating ores." G. B. Burton. Dated June 29th, 1897. Electric furnaces.—Ores are dried, roasted, and smelted in furnaces in which the heat is produced by passage of electric current either through a metal or other conducting coil, or a carbon rod, covered by the ore, or through a body of ore placed between two electrodes. Reducing agents may be mixed with the ore. The furnace may also be used for making calcium carbide. Alternating current is preferably used, and is regulated to increase the heat in successive stages of the treatment. In the furnace a glazed fireclay body contains a perforated hollow helix on a pipe which is rotatable by gearing to stir the ore. A coil of pipe may replace the pipe and helix. The pipe, &c., may be made of a copper-antimony alloy. Electric current is passed through the pipe and helix by terminals and clamps. Air may be introduced through the pipe by a lower valve, and gases are delivered through an upper valve, or through a valve and a tube made in sections. This contains baffles to stop articles deposited by the gas, and may be provided with magnets to stop magnetic particles; it ends in liquid in a tank. Liquid products are discharged at a tapping hole in the base, which rests on radially removable supports. When the current is to be passed through the ore itself, the tube is divided, each part carrying a perforated disc electrode in place of the helix, the upper part of the tube, with its electrode, is vertically adjustable. 25 claims.

15,486. "Improvements in apparatus or means for charging accumulators." H. S. Cox. (The Cox Thermo-Electric Company.) Dated June 29th, 1897. In order to charge accumulators from a generator of low voltage, the cells are arranged singly or in groups which are successively charged. The cells are arranged in groups which are connected by conductors alternately to contacts insulated from one another but cross-connected by conductors. Rubbing on these contacts are bushes mounted on the rotary shaft. Current is supplied to the bushes from the generator. The shaft is rotated by clockwork or other mechanism; each group of cells is thus charged for a certain time. The pairs of contacts may be arranged otherwise than in a ring, the bushes being successively moved over them. 5 claims.

15,490. "Improvements in electric heaters." G. B. Fraley. Dated June 29th, 1897. Current is passed through a series of carbon blocks, or a continuous carbonised conductor, enclosed by firebrick blocks. In the stove described, a hollow firebrick block in a casing has channels of U-form in its sloping front, containing balls or other blocks of carbon; the channels are open to some extent, before and behind the balls. The channels terminate in metal tubes which contain weights to press the balls together, and are connected with electric supply conductors. Both light and heat are produced by this apparatus, some combustion taking place; the ashes fall inside the block. When the weights have fallen so that pins on them rest on the bottom of slots in the tubes, more conducting blocks are introduced, after removing covers and the weights. The casing front is closed by doors containing mica sheets. Carbonised paper or like conductor is enclosed in grooves between blocks, and connected to terminals; the blocks are bolted together. Metal sheet conductors may be enclosed similarly between blocks, near the face of these, and are provided with rearward extensions to hold them in place. Or conductors may be formed by painting mixtures of powdered carbon and saccharine material into grooves in the blocks. Such apparatus is applicable for broiling or cooking. 17 claims.

15,491. "Improvements in electric heating apparatus." G. B. Fraley. Dated June 29th, 1897. Current is passed through a resisting wire coiled on asbestos or other non-conductor surrounding a mica-covered cylindrical core. The wire is also covered with a thick layer of a mixture of talc, silicate of soda, and carbonate of soda or other insulating material not shown. The core may be of copper slit longitudinally and perforated to pass a limited air current. Reflectors or baffles are fixed within or near its ends. The core is supported by a cap adapted to screw into a metal sleeve in a porcelain or other holder. The upper end of the wire is connected electrically to the core, cap, the sleeve, and a terminal; the lower end is connected to a central screw on a porcelain disc, this making contact with a plate and second terminal in the holder. For alternating currents the core is provided with slits extending partly along it from opposite ends alternately, so that the heating currents may be induced in it, or the core may be a conducting plate rolled up into several layers with intervening insulation, the inner and outer ends of the plate being connected electrically by rivets. In this form the core is carried in clamps near its ends. One clamp is insulated, and the ends of the wire are connected with the clamps. Additional layers of wire may be used, separated by asbestos. 15 claims.

15,503. "Improvements in electric arc lamps." O. Imray. (The Pennsylvania Salt Manufacturing Company.) Dated June 29th, 1897. Relates to a clutch-lamp provided with improved feeding mechanism. The upper carbon carrier passes between V-shaped jaws carried by levers which are pivoted on a disc, and are supported by links on the core of a solenoid. When the core falls sufficiently the disc rests on stops, and the jaws release the rod. The upper carbon passes through a lid having a flange resting on the inner globe, the dimensions being such as to permit some lateral play of the cover with the carbon. The inner globe may be held by a ring bearing on a shoulder in it, and screwing on a screw surrounding the lower carbon-holder. This is attached to the frame of the lamp by insulated screws; the carbon is held by a pivoted shutter and clamping-screw. The outer globe is secured in a cup which is supported by a nut and bolt on a part of the frame. The bolt has a cross-head which may be turned and lowered through slots in the part when the outer globe is to be lowered. When in place the nut serves to raise the outer globe into contact with a cover on the lamp frame. A pin and collar limit the motion of the bolt and nut. 6 claims.

15,510. "Improvements in secondary or storage batteries or accumulators and in the manufacture of the same." J. P. Clare, G. E. Hatch, and J. H. Taylor. Dated June 29th, 1897. In making the electrodes, active material is first formed on the metal plate itself by electrolytic action, and then active material or material to be rendered active, in a granular or pulverulent condition, is packed round the plate, and the electrolytic action is continued until the two masses are firmly united together. The plates and the active material are contained in a casing formed of large porous terra-cotta plates made up of separate sections fitted together and having recesses, pits, grooves, or cells, on their inner surfaces to hold the active material, and grooves near their edges for the insertion of thick rubber to make a water-tight joint. The terra-cotta sections are made of different sizes, so that when built up into plates, the horizontal joints in one plate are not opposite those in adjacent plates. The terra-cotta plates have ribs on their outer surfaces, and those in adjacent plates are preferably at right angles to each other. A number of elements so prepared are held between plates of hard rubber by rubber bands. 6 claims.

15,607. "A method of effecting multiplex telegraphic and telephonic communication, and apparatus for that purpose." J. Imray. (La Societe Anonyme pour la Transmission de la Force par l'Electricite.) Dated June 30th, 1897. Relates to a system of multiplex telephony and telegraphy, in which two lines connecting two central stations are provided with synchronously driven distributors, and the various subscribers are connected to single or grouped sectors on the distributors. When telephony and telegraphy are carried on simultaneously, two sets of distributors are employed, the telephone signals being sent on the metallic circuit, and the telegraph signals being sent on the metallic circuit as the line with an earth return. The signals are kept separate by resonators and condensers. The distributors are driven by motors or clockwork, separate sectors being employed for sending the synchronising currents; or the metallic circuit may be used with an earth return, in multiplex telephony, for the motor synchronising circuits, double primaries of transformers being connected in each of the leads. In this case the secondaries are in loops at each end with the distributors and the subscribers. Several arrangements of these circuits are described; in one of them the main line alternating current bell call circuit is arranged as a shunt to the motor circuit. In another form the double wound armature of a continuous current generator for the telephone currents is arranged with one winding in each of the metallic lines. The armatures of the distributor motors are preferably screened with copper end discs and connecting bolts. A telephone relay is described, in which the coil is enclosed in a magnetic shell, the armature carrying a microphone in circuit with a local battery and receiver. 4 claims.

15,560. "Improvements in electrical switches." J. W. Swan. Dated June 30th, 1897. In order to prevent arcing, an insulating wall is arranged between the terminals. Walls or projections are fitted on the base, and separate the terminals. The circuit is completed between the terminals by the bridge, to which a quick break is given by the spring, the handle being formed to give the required play. In a modified form, the wall is circular, one fixed terminal being within and the other without. The bridge is formed with one arm shorter than the other. 2 claims.

1898.

468. "Improvements relating to enclosed motors or dynamos." P. Rosling and H. W. Appleby. Dated January 7th, 1898. A dynamo armature shaft is mounted between the armature and case enclosing the dynamo and the vanes of a fan by which air is drawn into the enclosed casing from the outside atmosphere through a suitable opening which may be provided with a filter of cotton wool applied in a manner so as to extract from the air any moisture, grit, &c., that might be detrimental to the commutator, &c. 1 claim.

532. "Improvements connected with electric lamps and switches." W. M. Walters. Dated January 10th, 1898. The object of the inventions is to provide appliances whereby the illuminations in a room may be regulated. For this purpose a small incandescent lamp is carried in the box provided with the usual contact pieces. The switch lever is so arranged that when the main lamp or lamps is or are switched off the small lamp is switched into the circuit in place of the main lamp. 2 claims.

3,539. "Improvements in and relating to electric heaters." E. F. Porter. Dated April 12th, 1898. Relates to electric heaters, especially to the kind described in specification No. 5,595 of 1891. Consists in making the fan blades themselves of a material which will act as a resistance, and passing the current through conductors on the blades. 9 claims.

THE DISTRIBUTION OF ELECTRICITY AND HOME INDUSTRIES.

IT was once remarked by a very eminent man in this country that the distribution of electricity might prevent, to some extent, the aggregation of workpeople which we witness to-day in the great factories and workshops. Although it might appear an ideal state of existence to go back to the time when the weaving and kindred industries were carried out in the homes of the people, there is little doubt that the question of production might be very seriously influenced. There is a good deal of work which is capable of being carried on in the homes of the people, and if a power of any description, that was easily regulated and controlled, were available, it could hardly be doubted that there might be considerable extension of home work. Undoubtedly, small industries have been affected by the introduction of electric power, and an investigation into the uses of electricity in many of our large towns, even with the limited work that is being done, would be distinctly interesting. We are looking forward to the day when the complete schemes of the great power companies will enable electricity for power purposes to be obtained in places that are removed from the great industrial centres, but which, nevertheless, carry on small home industries. In these days, when the attention of most people has been directed to the distribution of large powers over long distances, it is not surprising that most interesting examples of transmitting electricity over small areas have escaped attention. One of the most interesting examples of power transmission is one in the district of Saint Etienne, where a most material effect has been produced upon an industry that has been for the most part carried on by the workpeople in their own homes. The ribbon industry of the district of Saint Etienne is one of the most ancient in France, and it will afford some idea of the importance of the industry when it is mentioned that in the district surrounding Saint Etienne there are probably 30,000 looms, there being 15,000 in Saint Etienne alone. Before the introduction of electricity, these looms were chiefly driven by hand, the weavers employing occasionally skilled assistants, or, in many cases, using the skill of members of their families. Some years ago an interprising electric company founded electricity works in the district, which were originally situated at Saint Victor sur Loire, some eight or nine miles from Saint Etienne. The original plant consisted of three turbines of 300 H.P. each, a stand-by being provided in the shape of two 300-H.P. engines, which were utilised in the event of a water-power failure. Some time after this company started operations it was incorporated with a rival concern, and at the present moment the company is supplying power over a district of some 24 miles in extent, power being chiefly employed for the purposes of driving weavers' looms. The system of generating and distribution is the three-phase, and current is conveyed throughout the district by 68 miles of wire. Spread over the district are 30 sub-stations, in which transformers are placed to reduce the voltage of the current, which is delivered at 5,200 volts, to a pressure of 190 volts for motive power and 110 volts for

Digitized by Google

lighting purposes. The total power of the plant employed by the company at the various generating stations amounts to 2,000 H.P. Throughout the district there are 8,000 lamps in use, and 2,500 looms are now being operated by means of electric motors. On an average a ribbon loom requires ¼ H.P., and the charge to each consumer for the power necessary to drive a loom is £4 1s. 6d. per annum, or 8s. per month. From all accounts it is apparent that the ribbon industry has been materially affected by the introduction of electric power, and the output of individual looms has been greatly increased since the introduction of the electricity works.

MOSAICS.

Sir William Preece, as President of Congress of the Sanitary Institute, last week delivered an address at Southampton to upwards of 1,700 delegates, on the advantages of pure air, pure water, pure food, pure dwellings, and pure bodies. Following the precedent of another President, he made frequent use of Biblical allusions; the address was, in fact, an appreciation of the skill of Moses as a sanitary engineer. Moses, according to Sir William Preece, was the greatest sanitary engineer the world has known, for in the regulation of the food supply of the Israelites was displayed, in the opinion of Sir William, that profound knowledge of the hygienic requirements of Eastern nations which has determined the healthy and cleanly lives of the Jews at the present day. To Sir William, the book of Leviticus is a treatise on hygiene, and the Jews the cleanest race on earth. The pity is that they don't all look it.

It must be confessed that there are many reasons for objecting to Biblical allusions when they form the basis of a presidential address to a non-religious society like the Sanitary Institute. Unless very carefully handled, such allusions may easily be misunderstood; they are nearly always in questionable taste, and they are nearly always fallacious. The fallacy of upholding Moses as the founder of cleanliness, is obvious; for the grown-up daughter of Pharoah was taking her customary morning bath before Moses was out of his little bulrushes. Indeed, it was on her way to the bathing machines that she discovered the baby; a proof that not only bathing, but "mixed bathing," was common in the earliest dynasties of the Egyptians. Later on in life, it must be admitted, Moses showed some proclivities towards hydrostatics, and evinced some marvellous knowledge in matters of commissariat. Unfortunately it is futile for a modern sanitary engineer to follow the methods of the great Levite, for he was favoured in his foraging by phenomena peculiar to the exigencies as they appeared—phenomena which in the World's history are never likely to recur. The modern engineer is, so to speak, not to the manna born.

There is comfort in the thought that, of all the Institutes, one is sanitary; but to the casual observer it must seem something of a mystery that this one Institute should choose its president from the ranks of electrical engineering. It is really wonderful to contemplate how much the world appreciates the intelligence of the modern electrician. Search the universe up and down, from Glasgow to Cape Town, from New York to Southampton, and you will find that where experts, diplomatists, presidents, and company-promoters are wanted, the electrician is always there. It is not too much to say that if the General Staff of France became disrespected to-morrow, if Kruger ceased from Krugering, if the Czar abdicated and went to Paris, a telegram addressed to the Electrical Engineers would ensure that every gap in the political fence should be filled, and that the world should still go on, talking.

In the case of the Sanitary Institute, however, it must be admitted that they showed a good deal of wisdom in going far afield for fresh ideas. It is a question of healthy homes, healthy workshops, healthy workhouses, healthy churches, healthy prisons, healthy post-offices; and it is improbable that any one man should have experience of all of these at once. As an electrician, Sir William Preece was able to call attention to the advantages of electrical methods of ventilation and illumination, and he did well to emphasise the merits of dust-destructors. We may smile at his wanderings in the wilderness of Shur, but there is no doubt he imparted some freshness to the bitter waters of the usually dull proceedings; and in addition he gave the Sanitary Congress some good practical advice in directing their attention to the housing of the poor.

THE DIFFERENCES OF EXPERTS.

The Newcastle Corporation, which has been for something over two years violently agitated on the subject of overhead tramways, and its Tramways Committee has arrived at last at a sensible decision. The main question before the Council for some time past has been whether it was advisable to adopt a overhead or a conduit system in the central streets; but on the advice of one of its experts, it has decided to equip the central portion of the town temporarily with overhead wires. The Committee has arrived at this decision in a somewhat curious manner. It has had abundant expert testimony on the subject. Prof. Kennedy was commissioned to provide a report, Mr. Charles Hopkinson was asked to give an opinion, and Mr. Laws, the borough engineer, was likewise requested to give his opinion. In a multitude of counsellors there is wisdom, but there is also considerable difference of opinion. Prof. Kennedy, in his report, follows fairly closely the views which he put forward in his report to the London County Council. He points out that there is no difficulty in obtaining successful results from a combined system of overhead and conduit, and he takes a favourable view of the surface contact system, and declares that it would not cost more per mile than a really well-arranged overhead system. On this point we imagine there will be considerable divergence of views. Apart from the question of whether it is possible at the present moment to obtain a surface contact system which may be expected to meet the very trying conditions of street life, it is doubtful whether a contact system could be equipped for anything like the sum that is necessary to put up the best overhead system in existence. From an intimate knowledge of all the contact systems which have been brought to the notice of tramway authorities, we do not think that any municipality would be justified in spending a single penny on them. Clearly and emphatically, we state that such systems have not gone beyond the experimental stage, and if a municipality adopts surface contacts, it ought clearly to recognise that it is doing nothing else but carrying out what might prove to be very expensive experiments. The advice of Mr. Charles Hopkinson to the Newcastle Corporation is entirely contrary to, and probably more precise than, that of Prof. Kennedy. He states, on the subject of contact systems, that "The greatest working difficulties would arise after a period of use." He truly points out that the system had not been in commercial use for a long enough time to demonstrate that the possibilities of breakdown were overcome; and where such systems were in use the climatic conditions were less severe than in Newcastle. It is quite possible that a surface contact system may be evolved in the next year or two which will justify its adoption, but at the present moment we should counsel hesitation on the part of the municipality to adopt what at the best must be an expensive system. It is satisfactory to find that Mr. Charles Hopkinson's advice to erect the overhead trolley system in the central portion of the town has been accepted; at the same time we should just like to point out that the difficulties of a municipality when considering electric tramway matters are very materially added to if they seek too much advice. In this particular case both Prof. Kennedy's and Mr. Hopkinson's reports were submitted to Mr. Laws, the city engineer, and the consequence is that he agrees with neither. Indeed, Mr. Laws goes so far as to state that the best plan will be to put down a surface contact system at once in the central streets. With such marked differences of opinion before it, it is satisfactory to find that the Newcastle Committee can arrive at what must be held to be a reasonable decision.

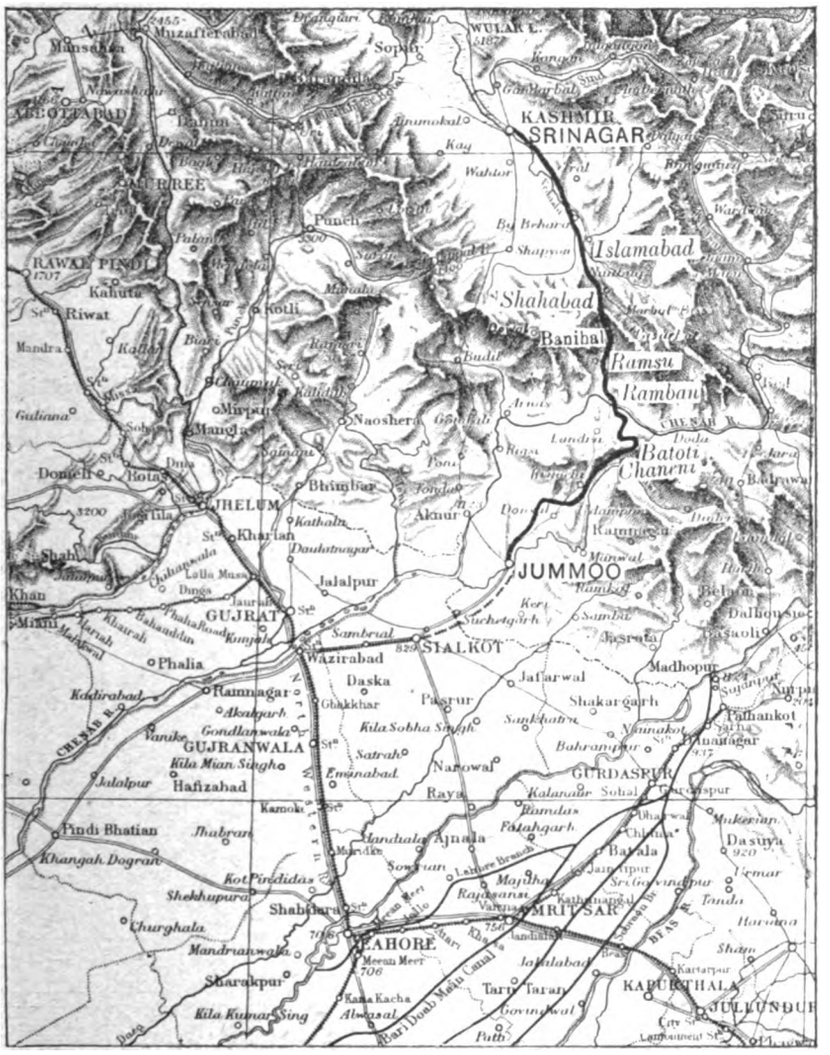
KASHMIR ELECTRIC RAILWAY SCHEME.

Speaking politically, the area covered by the title Kashmir extends to about 300 miles east of Rawal Pindi, and to about the same distance north of Lahore, the western and southern frontiers being distant from these places about 30 and 70 miles respectively. What, however, is historically and geographically known as Kashmir is a valley some 70 miles by 20, having a general level of 5,000 feet above the sea, lying north-west and south-east, and surrounded on all sides by mountains, some of which attain an altitude of 16,000 and 17,000 feet.

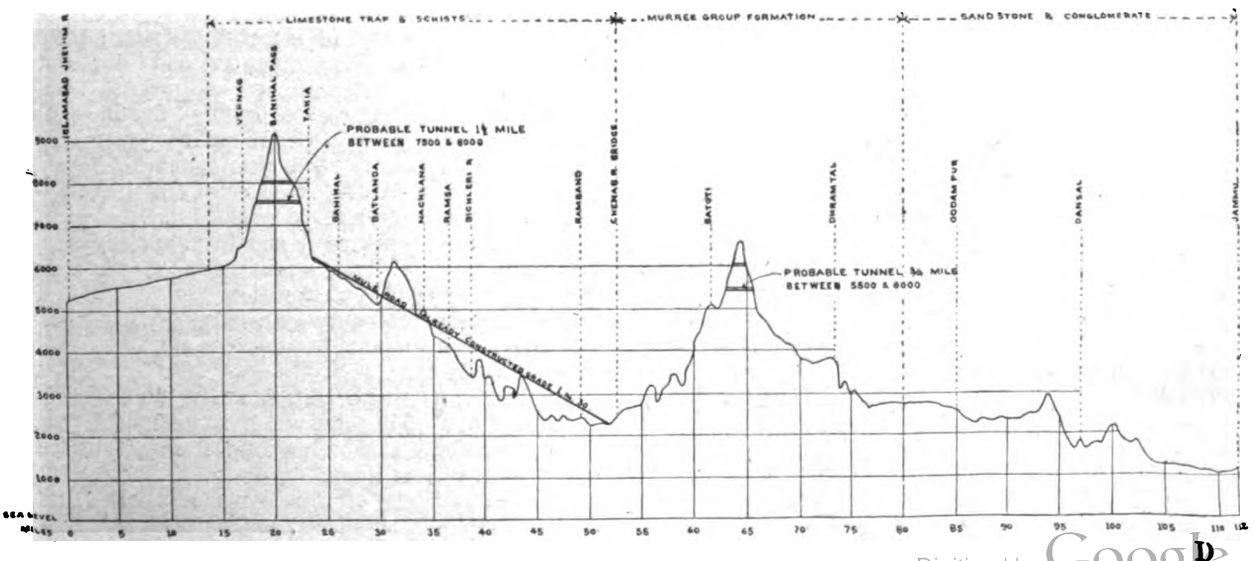


The Valley of Kashmir is watered by the Jhelum, which, rising in the south-east, flows into the extensive Wular Lake, and then making an abrupt turn to the west, flows down into the plains of India through a series of gorges. The capital, Srinagar (pronounced Shrinugger), is situated on the Jhelum, almost in the centre of the valley.

Srinagar is accessible from the south by the gorges of the Jhelum, and by a limited number of passes which cross the main mass of the Himalaya mountains. A cart road has been constructed along the Jhelum route, the distance between Srinagar and Rawal Pindi being 198 miles. Before this road was made available for wheeled traffic, the bulk of communication was carried on across the Pir Panjal and the Banihal Passes, the former being 11,400 feet, and the latter 9,700 feet at summit.

Notwithstanding the formidable natural obstacles in the way of railway communication between the Valley of Kashmir and the outer world, various projects have from time to time been brought forward with this end in view. In 1886 General de Bourbel directed an investigation into the possibilities of establishing a railway, the routes considered being (1) from Rawal Pindi, on the North-Western Railway, up the Jhelum Valley, *viâ* Abbottabad, with an alternative route starting from Mandra, 20 miles lower down the line; (2) *viâ* the Pir Panjal Pass, and (3) *viâ* the Banihal Pass. In 1890 the Jhelum Valley route was surveyed, and estimates prepared, but the cost was considered to be too great, and the scheme was abandoned. At the same time General de Bourbel reported in favour of the Banihal route. The matter was, however, not considered again seriously until recently, when Mr. M. Nethersole, State engineer to the Kashmir Durbar, brought forward a proposition for working the line by electricity, with proposals as to the route to be adopted differing considerably from those hitherto suggested. The Indian Government has considered Mr. Nethersole's report, and has given formal sanction for the commencement of the necessary survey.

The accompanying map indicates the general alignment of the proposed railway, and the section is that along the existing mule track. The line, which will probably be of 2 feet 6 inches gauge, starts from Jummu, the second capital town of the State, which is already connected by rail with the North-Western system. Jummu is situated nearly at the junction of the rivers Tawi and Chenab, at an elevation of 1,000 feet above sea level, and it is at this point that the boldness of Mr. Nethersole's plan becomes apparent, for he



Digitized by Google

proposes to leave the valley of the Chenab and strike up the northern slopes of the Tawi valley, passing through Udhampur and crossing the Bototi Pass at an elevation of 6,000 feet, and descending again to meet the Chenab at Ramband.

There appears to be abundant reason why this plan should in the end prove less costly and more satisfactory than that originally suggested by General de Bourbel, who contemplated working up to Ramband by the east bank of the Chenab. The distance from Jummu to the summit of the Bototi is estimated at about 65 miles, with grades averaging 1 in 30, but rising to as much as 1 in 20 for part of the way. The descent to Ramband would be made by a grade of 1 in 30 extending for about 25 miles.

Ramband will in all probability be selected as the point where the larger part of the power required for working the line will be generated. The report gives particulars of as many as 11 places within reach of different points of the proposed route where water-power is available. Of these, Ramband is considered to be the most favourably situated. It is actually on the line; it is about midway between Jummu and Srinagar, and there is a practically unlimited amount of water-power, the minimum discharge of the Chenab at Ramband being estimated at 6,000 cubic feet per second, with an average fall of 20 feet per mile.

On leaving Ramband the line follows the existing mule road up the steep ascent of the Bichlari valley for a distance of 27 miles at a grade of 1 in 30. On nearing the top the grade will be increased to 1 in 20 for about 10 miles, and the actual summit pierced by a tunnel of 1½ miles in length, at a height of 8,000 above the level of the sea. Within a short distance of the tunnel the head waters of the Jhelum are met with, and it is estimated that 1,000 H.P. is available at this spot. The importance of having water-power at this elevation will be appreciated when the question of the transmission for working the heavy grades at each end of the tunnel is gone into.

After quitting the northern exit of the tunnel the line descends to Islamabad in the Valley of Kashmir by a rapid fall of about 2,500 feet in 10 miles. The remaining section of the route is practically level, the distance into Srinagar being 45 miles, making in all a length of 180 miles from Jummu.

In forming an estimate of the amount of power that will be required, Mr. Nethersole has calculated that the probable traffic could be dealt with by 10 trains of 100 tons each per day, and that it would be necessary to provide turbines of not less than 5,000 H.P. This estimate of power, as is carefully stated in the report, is based on very rough approximations, and will have to be checked, and revised if need be, when the whole question of the electrical equipment is gone into in detail.

An average speed of 12 miles an hour over the whole line is recommended. This involves large variations of speed according to the grade upon which the train may happen to be running. Thus on a grade of 1 in 20 the estimated speed is 8 miles an hour, while on a level it exceeds 20 miles an hour. These conditions of working raise some interesting points in connection with the design of the controlling system, especially if polyphase motors are to be used, which is almost a foregone conclusion.

The financial probabilities of the scheme are promising. Taking the working expenses at 60 per cent. of the gross revenue—a high figure where the power is obtained entirely from water—it is estimated that the net revenue will represent 8·8 per cent. on the maximum and 13·2 per cent. on the minimum capital cost.

The scheme, as it is presented in the report, is altogether a remarkable one, and we congratulate Mr. Nethersole on having convinced the Government of India of its soundness. There are no doubt technical difficulties, but they are of the same order as others which have been met with and successfully overcome. To the professional mind the scale on which electrical traction will be employed lends a peculiar interest to the undertaking, while the political and commercial results of the new railway must attract public attention to it in no ordinary degree.

THE GENERATION OF POWER FOR ELECTRIC TRACTION.

By J. GRAY SCOTT.

(*Concluded from page* 220.)

In dealing with the subject of the generation of power, no treatise would be complete without reference to the machinery installed at the generating station.

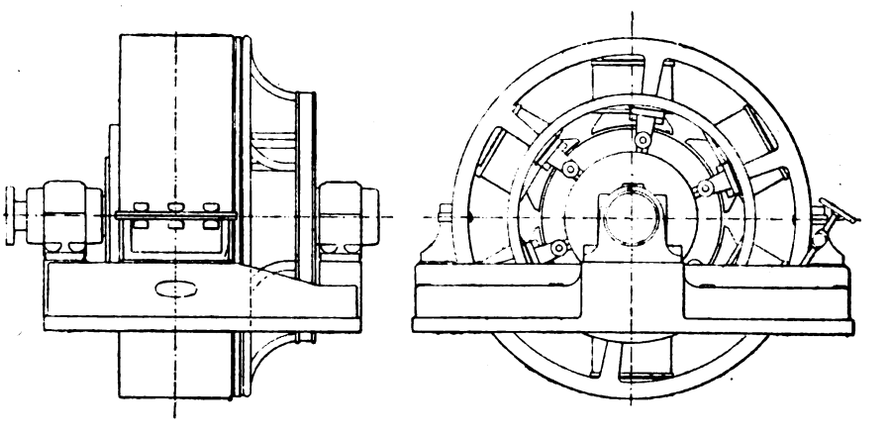
The engines at Bradford are of the well-known Willans central valve type working triple expansion at a pressure of 180 lbs. per square inch.

The I.H.P. of each engine is 600, at or about 300 revolutions per minute.

The satisfactory working of these engines, even under the stringent conditions associated with traction work, goes to prove the high state of efficiency both as regards working and governing which has now been attained, and it is more than probable, that with the development of traction work, high speed engines will continue to be very largely employed.

These engines are too well-known to require description.

The dynamos to which they are coupled offer considerable interest however, being at the time of their installation the largest continuous current generators manufactured in this country; the newer type has not, so far as the author is aware, been previously described.



The general appearance of these machines may be seen from the side and end elevations reproduced herewith.

The field-magnet yoke is nearly 8 feet in diameter, and the machine stands some 6 feet 6 inches from the floor level.

The yoke ring and poles are of cast-steel.

The armature, which is slotted, has a six circuit single winding and is nearly 48 inches in diameter; the commutator is about 36 inches diameter and has some 324 segments.

There are six sets of carbon brushes—five in each set, the connecting cables being carried round the outer ring of the circular brush rocker to which also the brackets carrying the brush spindles are fixed—but insulated therefrom.

The brush gear carriage is mounted on the periphery of the field-magnet yoke ring, and the necessary adjustment may be made by the hand wheel shown on the lower right hand extremity of the end elevation.

The machine is on a separate bedplate from that of the engine, and the armature has bearings of the swivelling and self-lubricating type.

The output for which each generator is designed is 750 amperes at 500—550 volts, which it need hardly be said is easily obtainable—moreover, a considerable overload has been sustained at various times.

The weight of one of these dynamos is over 21 tons, that of the armature being about 7 tons.

Digitized by Google

The magnet coils are compound wound, the shunt winding alone being used when the machine is employed for lighting —the series coils being requisitioned only for traction supply.

The six coils of the shunt winding are connected in series and have a total resistance of about 41 ohms.

The resistance of the armature (from brush to brush) is less than $\frac{1}{100}$th of an ohm.

In tests of two machines by Hopkinson's method the following figures were obtained :—

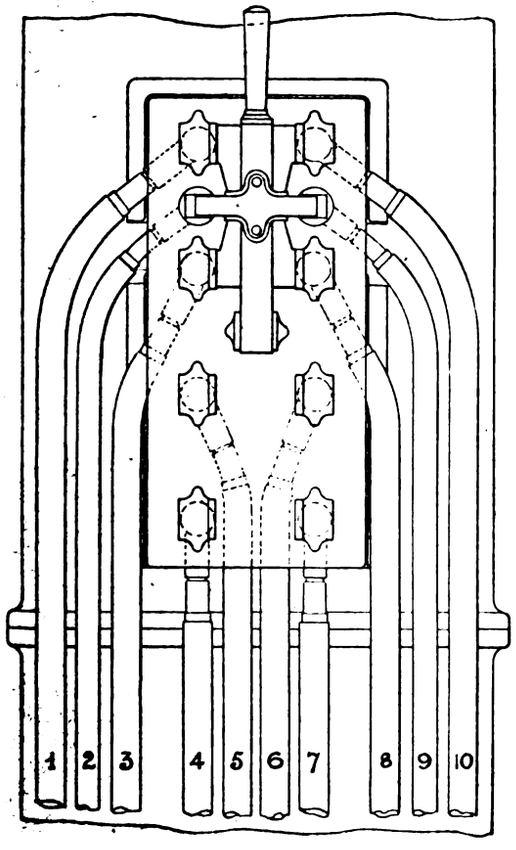
At quarter load, 90 5 per cent.
At half load, 94·25 per cent.
At full load, 95·5 per cent.

Presuming the machines to be of equal efficiency, we get a commercial efficiency of each machine of

97·7 per cent. at full load.
97 per cent. at half load.
95·1 per cent. at quarter load.

In a previous section the author pointed out the importance and convenience of interchangeability of the generators in a combined lighting and traction station.

In order to effect this as may be desired each machine has fitted a change over switch as shown in the following drawings :—



The switch is of course double-pole, the two pairs of inner contacts being connected to positive and negative dynamo terminals respectively ; of the outer contacts, the upper pair are connected with the positive and negative bus bars respectively of the traction switchboard, while the lower pair are connected with the positive and negative bus bars respectively of the lighting switchboard.

In the position shown, the switch would connect the generator with the traction system, the series coils being now in circuit and the equaliser switch closed.

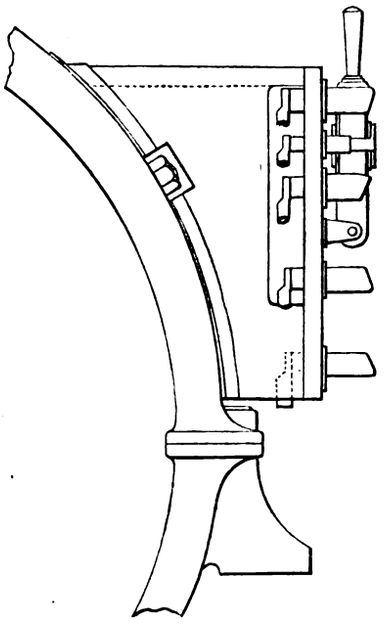
This switch is intermediate between the two upper pairs of main contacts, and its function is simply to connect together the positive brushes of those machines running in parallel on the traction system, and thus obviate the possibility of reversal due to the series winding.

Connection is sometimes made from each of these switches to what is called the equalising bar on the switchboard, but more often is simply connected to a cable in close proximity to the various machines and which equally well performs his function.

Referring to the cables which may be seen passing downwards from this switch it might be well to indicate their connections passing from left to right as numbered.

No. 1 connects the top left-hand contact to the positive bus bar on the traction board, through the series coils on the field magnets.

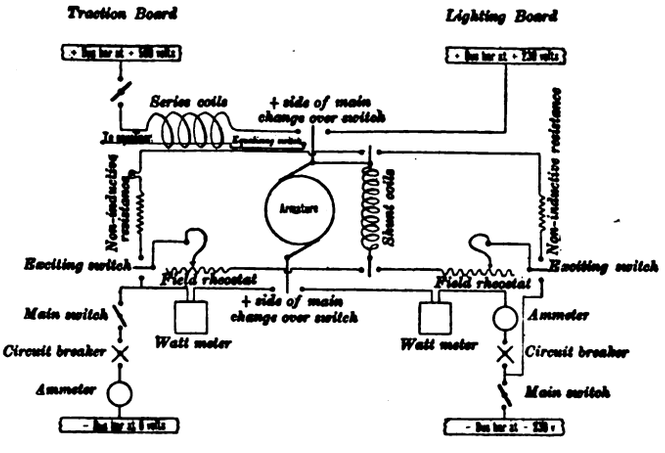
No. 2 connects the equaliser switch to positive brush for equalising when two or more machines are running in parallel.



Nos. 3 and 5 connect the two intermediate left-hand contacts to positive pole of dynamo.

Nos. 4 and 7 connect the two lower contacts to positive and negative bus bars respectively on the lighting switchboard.

Nos. 6 and 8 connect the two intermediate right-hand contacts to negative pole of dynamo.



No. 9 connects equaliser switch to equaliser bar or cable.

No. 10 connects top right-hand contact to negative bus bar on the traction board.

The accompanying diagram clearly sets forth the suitable connections for the interchange.

In conclusion, the author has to express his appreciation of the facilities afforded by his late chief, Mr. Gibbings, of Bradford, in the preparation of the foregoing matter.

The thanks of the author are also tendered very sincerely to those of the staff at Bradford who were good enough to render him assistance, and also to Messrs. R. W. Blackwell and Co. and Messrs. Siemens Bros. & Co., for kindly supplying blocks and drawings.

INDISPENSABLE ACCESSORIES OF ELECTRIC TRACTION.

By HENRY E. P. COTTRELL, A.M.I.C.E.

(*Continued from page* 351.)

Mechanical contact bonds constitute, on the contrary, a very numerous class, which falls naturally into two divisions (multiple and simple bonds), the first sub-divided into polymetallic and monometallic, and the second into composite and uniform, in accordance with the character and condition of the metal or metals used in their construction.

The "American solid bond" and the "American flexible bond" are multiple polymetallic bonds, where ordinary steel wire and stranded steel wire respectively constitute the bond (figs. 83 and 84), connection being made with the rail web

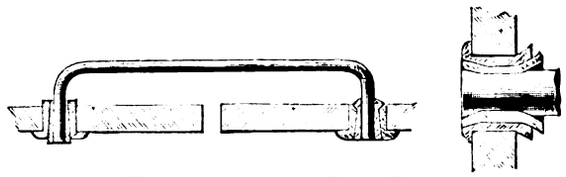

Fig. 83.—American Solid Bond.

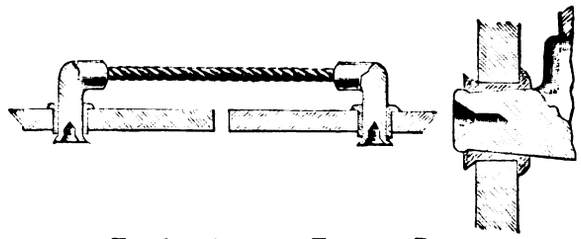

Fig. 84.—American Flexible Bond.

in the first case through tapered copper bushings and sleeves, contact being ensured by driving home the bushings, while in the second the stranded wires are gathered into the thimble ends of conical copper bushings, which are expanded by driving a conical wedge home in the opposite end, when they are passed through the sleeves lining the holes in the rail webs. The defects of these are practically the same as the preceding ones, multiplicity of gaps, deficient capacity, and excessive length.

In the "Grauten bond" ordinary steel wire again composes the bulk of the bond, held in clips with grooved heads riveted through the web, as shown in fig. 85. These clips are

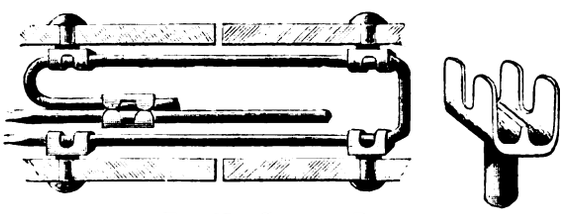

Fig. 85.—Grauten Bond.

of a composition rich in copper. The objections to this bond are also deficient capacity, excessive length, and multiplicity of gaps.

The "Stern & Silverman bond" substitutes a copper wire for the bond proper. This is held in a steel chuck screwed, split, and tapering at one end, on which a binding nut is passed. The chucks are screwed into the web, the copper wire passed through and secured by the binding nut, screwed over the tapering end. The objections to this bond are multiplicity of gaps and deficiency in closeness of contact, the contact between the chucks and the web being necessarily loose and subject to ready oxidation, and that between the copper bond and the chucks being almost as bad. The length is also objectionable on the ground of cost. (Fig. 86).

The "Bryan bond" is another multiple polymetallic bond belonging to Group A. Here the wires composing the bond are clipped between two corrugated washers, one of steel and the other of copper, contact depending on the screw pressure of the bolt passing through these and the rail webs and on con-

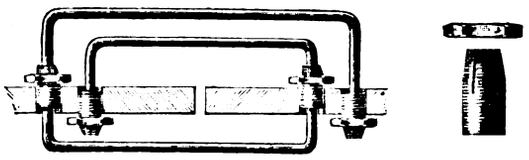

Fig. 86.—Stern and Silverman Bond.

dition of the surfaces. In practice, the closeness of contact cannot be secured, nor can oxidation be prevented in the excessive number of gaps.

Among multiple monometallic bonds, of which steel is the metal used, may be mentioned the "West-End bond" and the "Ohio Brass Company bond," in which steel wire composes the bond proper, the connections being made with the rail webs through tapered steel bushings and caps respectively, which are driven forcibly home. Their defects depend upon deficient conductive capacity and excessive length of the wire and multiplicity of gaps. The principal multiple monometallic bonds in which copper is the metal used are the "Johnson" and the "Columbia" bonds. The first (fig. 87) consists of five parts, a long copper rod, ends bent

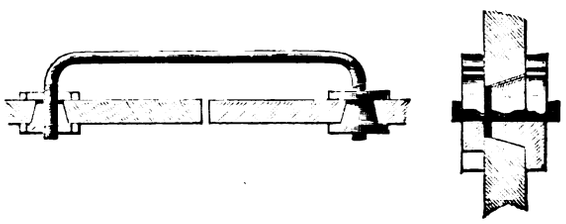

Fig. 87.—Johnson Bond.

at right angles and screwed, two conical tapered nuts, and two flat nuts. The latter are first screwed on the ends, which are then passed through the tapered web holes, and the conical nuts are then screwed home, making the contacts and fixing the bond. The objections are: multiplicity of gaps, impossibility of producing really tight contacts, and therefore of protecting contact surfaces from oxidation.

The Columbia bond has tapered conical heads with filleted base (fig. 88). Two tapered thimbles are inserted in the web

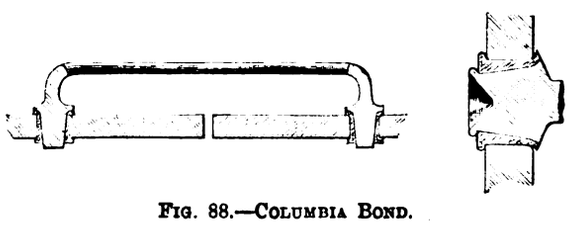

Fig. 88.—Columbia Bond.

holes, the conical heads are passed through these, and tight contact is ensured by setting up the conical head with a plug-headed hammer, or a screw press. The defects of this bond arise from the multiplicity of gaps, and the impossibility of ensuring a uniformly tight non-oxidisable contact throughout the contact surfaces by setting up from one end as described. Mr. Parshall's experiments previously referred to show how considerably the resistance in this bond can vary, the condition of holes and bond remaining constant, owing, presumably, to slight differences in the tightness of the contact surfaces, one being as low as 7·2 microhms, another as high as 9·5 microhms (per two terminals in series), a difference of 32 per cent., the holes being clean and bonds untouched in both cases.

The second or "simple" division of mechanical contact bonds remains to be considered, and this contains some of the most promising forms, as well as some that leave much to be desired. In the "composite" sub-division, one belongs to

Digitized by Google

Group A (the "Harrington diagonal bond"), and three to Group B (the "Forest City," the "Atkinson and Harrington ball bonds"). The Harrington diagonal bond consists of four copper wires rolled into tapering conical terminals ($\frac{3}{4}$ inch maximum diameter) which are inserted in diagonal holes in the rail foot. This is a composite bond, owing to the difference in conductivity in the rolled ends and the drawn wires, producing an increase in resistance analogous to the introduction of a gap between the rolled and drawn portions. The tapering ends cannot be driven so as not to work loose and do away with closeness of contact and protection from oxidation of the contact surfaces. Its length makes it also a very costly bond.

The Forest City (fig. 89) and Atkinson bonds closely

Fig. 89.—Forest City Bond.

resemble each other in appearance and method of application. They consist of strands of flattened copper wire uniting solid terminals, the first being cast and the second pressed on to the flattened copper strands. They are both composite bonds owing to the difference in conductivity of the copper in the wire strands and in the cast and laminated terminals respectively. This difference with its attendant increased resistance at the junctures of the different forms of copper is liable to be considerably augmented in the case of the cast terminals by these being very liable to contain blow-holes which greatly decrease the conductivity. Both bonds are fastened by the application of pressure through a press (bond welder) or a screw and ratchet clamp. Their defects are those inherent in bonds, the metal composing which is of composite character.

The Harrington ball bond differs from the "Forest City" bond only in having the terminals cylindrically perforated, and in being fixed by expanding them by driving a steel ball into the cylindrical perforation. Its defects arise wholly from the composite character of the metal of which it is composed and the increased resistance produced thereby.

(*To be continued.*)

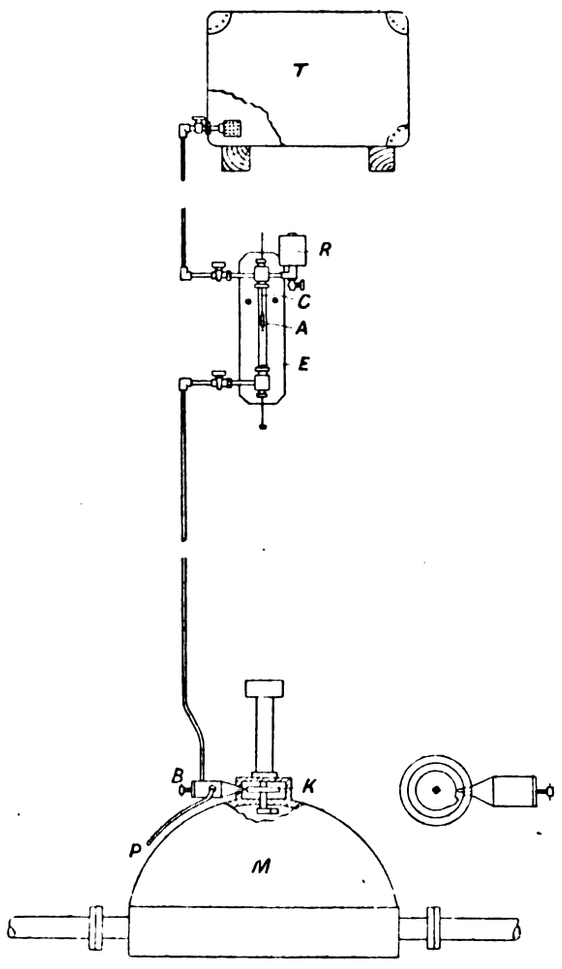
THE PURIFICATION OF FEED WATER.

By T. W. BLOXAM.

When considering the cost of maintenance of steam boilers —which constitutes a large percentage of the works' costs— the most important item, and the one where economy can be most easily effected, is that of labour for cleaning. This can be largely reduced by removing from the feed water the impurities which produce hard scale. The varying amount of attention paid to this point by steam users, drawing their supply of water from the same source, shows a lack of appreciation of its importance by many; for we find some spending several hundreds of pounds on a water-softening appliance, whilst others consider the occasional surfeiting of the boilers with anti-incrustation fluid of unknown composition all that is necessary. In most large installations a water softener is installed, but the cost of maintenance considerably reduces the economies it effects, and for every one of these there are 10 where soda solution or boiler compositions, costing several shillings per gallon, are either thrown into the feed tank without any regard to the varying composition and quantity required under different conditions, or else are not used at all. Where an excessive quantity is used expensive materials are wasted, and fittings injured by corrosion.

In some cases a small pump, actuated by the feed pump, is used to add the required proportion of reagent, but this method has not proved satisfactory owing to the difficulty of keeping the small valves in order and the plunger tight.

A considerable improvement on the pump is a simple piece of apparatus manufactured by Messrs. Kennedy, of Kilmarnock, and shown in the accompanying sketch.



It consists of a mushroom valve, B, which is periodically opened by a cam or tappit on the feed pump or water meter, allowing the reagent in the tank T to flow by gravity into the suction pipe of the pump, the quantity admitted being regulated by the float A, enclosed in a glass tube which it fits loosely.

The action is as follows:—When the valve B opens, the liquid in the tank flows through the controller carrying the float A with it until it reaches its seat, E, stopping the flow. When the valve B again closes, the float A returns to the adjustable stop C, and is ready for the next delivery.

By raising or lowering the stop C, the quantity delivered can be regulated to any proportion, which is maintained in spite of the rate of delivery of feed water varying. The movements of the float A indicate whether the apparatus is working properly or not.

The simplicity and small cost of this arrangement should recommend it to users of water softening reagents.

THE GLASGOW ELECTRICAL TRAMWAYS CONTRACT.

To repair an error is always difficult, yet we hope that Glasgow will find means to come to a satisfactory conclusion on the engine business. What is done cannot be undone. It is recorded that when a child had been receiving religious instruction she was so impressed as to inquire whether, having gone upstairs and come down again, it lay within the capacity of omnipotence to make it so that she had not been upstairs. So with Glasgow.

However, they have attempted a solution by awarding two

Digitized by Google

engines to the Allis Company at £28,000 each, and two to Musgrave's at £24,000, the extra £4,000 amounting practically to a bonus for about three months better despatch. This at least was the committee's resolve to recommend to the Council, although Bailie Thomson wished to award all four engines to Musgrave's, whose price was £95,516, against the Allis Company's price for £114,564. This motion was carried, subject to delivery, but Mr. Musgrave could not agree to the delivery terms. What surprises us is that some firm of marine engineers could not see their way to tender for these engines in the time required. What we consider should have been done was to have carried out the promise to have given freedom to contractors, and, at most, to have specified speed, diameter of cylinders, and stroke. Then, and then only, would there have been any semblance of equality. The position was a difficult one, but maintenance for 12 months would have been a safeguard against insufficient strengths.

Writing to the *Engineer*, Mr. H. Austen disallows the Allis Company's right to complain as they are doing, seeing that they put in at the top price, and under the rule practically controlling public tenders, had no chance of success at the price. They were properly disqualified by price, and ought to keep quiet, for they had no right whatever to expect to take the order from other firms who could and would supply fully equal engines at a less price. As regards the question of time for delivery, it is very largely the fault of such municipalities as Glasgow and others uninformed and hesitating, that electrical work has been kept back so much in England, and it is only right that manufacturing engineers should be allowed longer time. They would not have needed such time if the natural growth of the electrical industry had been allowed free play. Municipalities accept goods from abroad made under free labour conditions—in America there is no Truck Act—and entirely unhampered by specification, whereas an English firm is asked to rigidly observe an often impossible specification, and to pay certain wages called "standard," as to which there is no limit of meaning. This demand for a standard wage is simply a means of offence. It enables any Common Councilman to render himself obnoxious to the contractor, and it should be abolished. There is no justification for this clause in any contract on which foreigners have been also allowed to bid.

Turning now to the electrical equipment, we have a different story to tell. The specifications for this portion of the plant strike us as being excellent in every way, and just what was required. They are perfectly fair to any manufacturer who is able to turn out high-class and absolutely modern machinery of large size, and at the same time the buyer is fully protected.

We think with regard to the generators and rotaries that no English firm has any idea as to what must be done in order to build machines of this size to fulfil guarantees such as in the present case—as to delivery they would certainly be out of it.

Moreover, after carefully studying the specifications, in order to see as well as we can what was passing in Mr. Parshall's mind, we have no doubt but that Glasgow has done the best thing in retaining him as electrical expert, even when taking into consideration all that has been said on the engine side of the question, for we do not think that any English engineer has had sufficient experience to do what Mr. Parshall has done. The system is undoubtedly right, his ideas are very clear, and it is easy to see that he knows exactly what he is about.

Our further impressions on technical grounds may be gathered from the following notes on the Glasgow tramway specifications for (1) generators, (2) transformers, and (3) rotaries.

1. With regard to the specification for three-phase generators, we are unable to see that a better or fairer specification could be drawn up. It asks for nothing out of the common, and could be tendered for by half-a-dozen first-class firms.* The temperature rise is fairly liberal, but is it the common figure obtained with all such large units? The same remark applies to the fall of pressure allowed and to the efficiencies at various loads. Machines built on the lines indicated (which, as stated before, are practically the constructional lines adopted by first-class firms on the Continent and in the States) would come out reasonably light and cheap, while amply good enough electrically, and the buyer would have thoroughly reliable machinery.

The tests specified are reasonable, but perhaps would add somewhat considerably to the contractor's price on account of the size of the units. They are, however, none too stringent. With regard to delivery, the times allowed are very short, and no firm could deliver anywhere near the time stated unless they had already made similar machines, that is, unless they had the whole design and patterns complete.

As to whether any English firm could supply these machines, we are decidedly of opinion that there is not a firm in the country who could do so. Nothing of this size has been attempted up to the present by any firm here (alternators of the "ironless core" type are completely shut out, as being impossible), and they would not have the experience. That is to say, English firms could not guarantee the performance, owing to the want of experience in three-phase machinery of such an output and speed, and they could not deliver in anything like the time, as no English works are equipped to take this size and class of work.

2. *Transformers.*—Here, again, it is difficult to see where the specification could be improved on. The figures allowed for heating, drop, &c., are standard with any good maker of transformers, English or foreign, and are by no means outside commercial limits.

Any English firm having experience in transformer building could give the necessary guarantees easily but we do not think the delivery could be made so quickly as asked for.

The question here—England *v.* Abroad—would turn solely, we imagine, on the price and delivery.

The tests are reasonable and sufficient. The moderate heating asked for could not be attained without oil-cooling or air-blast, unless the transformers were made very heavy and expensive.

Nothing is said about protecting the high pressure terminals or their position.

3. *Rotaries.*—Nothing out of the way is asked for, and the guarantees, tests, &c., are by no means too stringent.

Efficiency and heating figures are quite normal.

Overload capacity (with fixed brushes) is rather high. The speed is left to the maker.

There is only one point about this specification that would appear to be rather vague, as follows:—The generators, transformers, and rotaries are all specified for on the basis that the load is *non-inductive*. In order that this may be so, it is clear that the rotaries are intended to be *over-excited* in order to get rid of the lag. The amount of over-excitation will naturally affect the clause dealing with parallel running. We think further details might have been given in order that tenderers could see exactly how the machines will be used. The compounding question is also affected by this over-exciting and parallel running. For instance, suppose a big load is put on—the series coils strengthen the field, and hence diminish the lag. This might affect the parallel running if the engines varied much more than the specified amount in the angular speed during a revolution.

These points, however, are perhaps covered by the "choking-coil" clause, which practically gives a free hand to the contractor as to what special devices he may employ in order to get the desired result.

Electrical Extraction of Iron from Ore.—The *Financial News* says that it is reported from Vienna that the Prague Iron Industry Company has commenced a series of experiments with a view to testing the commercial practicability of a new process which has just been discovered for the extraction of iron from its ores by means of electricity. "The idea of replacing the blast furnace by some form of electric furnace is not a new one, as is shown by the trials made in this direction in Germany in recent years, but it is considered that past failures do not preclude the possibility of the new process being tested at Prague proving a financial success and of great benefit to the iron trade in general."

* Other than English.

THE REPORT OF THE PACIFIC CABLE COMMITTEE.

(*Concluded from page* 268.)

According to the estimates made by Sir Sandford Fleming, founded on a very moderate treatment of the continuously-increasing receipts accruing to the existing companies for the 20 years preceding the date of his calculations, we find that he has taken 1898 as the first full year that the cable could be in operation, and that the gross earnings, reckoned at the low rate of 2s. per word for the Pacific cable, would amount to £110,000; for the year 1899, £126,500; and for the year 1900, £143,000. If from these estimated yearly earnings we deduct in each case the fixed charge for interest and working expenses of £75,000, we would have a surplus in 1898 of £35,000, in 1899 of £51,500, in 1900 of £68,000, showing a total surplus of £154,000 for the first three years the cable would be in operation. After these first three years, during which the cost of maintenance would fall on the contractors, this item would be a charge against surplus earnings. Sir Sandford Fleming has taken the annual cost of repairs and maintenance, interest, and working expenses, at £125,000, and allowing for this he finds that the total surplus in 10 years would amount to £742,000 on the assumption that the volume of traffic would increase at the normal rate. The low rate of interest payable on capital, owing to the guarantee of the British Government, is an important feature in these estimates. Apart from the figures given above, Sir Sandford Fleming directs attention to an advantage frequently overlooked, and to which the Committee make no reference in their report, viz., that the reduction of rates from 4s. 9d. to 3s. per word will, within the first year after the Pacific cable brings such reduction about, effect a gross saving in Australasia and the mother country of £190,000, a saving which will be repeated annually, and will be continually augmented by the growth of business. The indirect advantage to Canada will be great, and as the Pacific cable is now receiving the support of the Home Government, and absolute cash returns do not count for everything in the matter, we may well consider the indirect gain to the Dominion as not the least of the prospective profits. Miss Flora Shaw has pointed out that "Canada commands the commercial high road of two hemispheres," and the establishment of the Pacific cable is a necessary adjunct to this highway, all the more advantageous that, in itself, it will be self-supporting, if not a source of profit.

In their report the Committee are careful to state that they have been "actuated by extreme caution," and although we think that as regards the probable revenue the report is too conservative, still we are glad to see that here, as in other divisions of the report, the Committee have refused to accept, blindfold, the opinions and figures advanced by the representatives of the Eastern Extension Telegraph Company and other declared opponents to the Pacific cable, and this even, although the officials of the English Post Office have, in almost every instance, been more or less in agreement with those who have vainly sought to quash the project. In his report to the Canadian House of Commons, Sir Sandford Fleming has written very strongly concerning what appears to him to be an extraordinary unanimity of opposition; but we do not propose here to go further into this aspect of the matter. We have been contented to deal with figures and statements as we find them given in evidence, and our readers, like Lord Selborne's Committee, may find much interest in the process by which the figures and opinions of some of the witnesses have finally been arrived at.

VI.—If the Cable were to be National Property, what would be the Proper Method of Management and Administration?

We are quite in agreement with the report of the Committee on this head—that the general direction should be under the control of a small board, on which the associated Governments would be represented. It is true that, to avoid the petty jealousies which have frequently arisen in the past amongst the Australasian Colonies, it might be necessary to have a larger board than that which would be absolutely necessary for fair representation of the various parties to the Pacific cable scheme. But as the interest is a common one, we do not anticipate that much difficulty or delay would be caused by a very full representation. We are, however, clearly of opinion that it would be a most regrettable mistake to place on such a board any of these gentlemen who have shown themselves adverse to the laying of the Pacific cable. In the establishment and management of this work neither pessimism nor incompetence should have a part. These are not the qualities which are required to establish a satisfactory position in the face of powerful opponents.

VII.—What should be the Form of Contract offered to a Contractor for its Construction?

The Committee only touches lightly on this point, which, in view of the variety of opinion expressed in the technical evidence, is of some importance. We think that, as this is a subject connected with long deep-sea cables which have not as yet come under the control and experience of the Post Office authorities, it would be best that the Board of Management should nominate three representative cable engineers, professionally independent of each other, and unconnected with any manufacturing company. The engineers thus selected to draw up and submit to the Board of Management such specifications and terms of contract as they may agree upon; this draft form of contract should then be sent to each of the manufacturing firms, who should return the draft to the Board with such notes or suggestions as they may think necessary. The final form of contract on which tenders would be invited from manufacturers could then be decided on by the Board in consultation with their engineers. By this means the Board would have the advantage of finding before it the fullest information on the subject to be decided upon, as well as the opinions of all those most competent to deal with the matter. We are perfectly aware that this is not the usual procedure, but it appears to us the method from which the best results may be derived.

We have now dealt with all the points mentioned in the instrument of appointment of the Committee, but in the course of the evidence a considerable amount of attention was drawn to the question of duplication, a question which goes hand in hand with that of the durability of cables. Lord Tweeddale raised the question as to the need of duplicating cables, and in answer to a question (No. 1,968) says that duplication is a principle on which his companies have acted, and, again, in reply to question No. 2,107 *et seq.* says that duplication is an absolute necessity for safety. Sir W. H. Preece cannot call to mind "a single instance in which reliance has been placed in a single cable." There is no doubt that there would be an additional load on the Pacific cable cost were only the above opinions correct! But elsewhere in the evidence these opinions are not supported. Lord Tweeddale himself makes reference to the company's cable from Madras to Penang, but appears to forget that this main line cable to Australia and the Far East, laid in 1870, remained unduplicated for 21 years, also that his second Penang-Singapore cable was laid 22 years after the first, further, that nine years elapsed before the laying of the second cable from Java to Port Darwin, thus duplicating the only connecting link with Australia; again, that his company did not lay a duplicate cable from Australia to New Zealand until the first one had been working for 14 years, and finally, that the solitary cable which was laid between Singapore and Banjoewangi 20 years ago, and which is the only submarine cable link now connecting Australia with Singapore and the rest of the world, is only duplicated by the use of the Dutch landlines through Java. Thus, in the history of the Eastern Extension, &c., Company alone there is to be found an object lesson on the need for immediate duplication of cables! There are numerous other similar instances which may well have escaped the attention of Sir W. H. Preece, but which should have been well within the knowledge of the representatives of the Eastern Extension, &c., Company. We could cite many instances in support of our opinion that the durability of well designed cables, laid after a careful survey has been made, is much underrated, owing to the shortness of the life of many ill-designed lines, but space will not permit us to enter on this. The Committee advise the laying of a duplicate cable, which they think would be advantageous, although not an immediate necessity.

There are many points of minor interest on which we might enlarge, but it is sufficient that the principal considera-

Digitized by Google

tions have been laid before the readers of the Review, fairly and impartially, we believe. We cannot leave this subject without an expression of hope that the Pacific cable project, now on the verge of accomplishment, and which we have consistently and continuously advocated ever since its inception, may be successfully achieved, and we also hope that in time even those who have not strenuously opposed it, may agree with us in the opinion that the establishment of such a cable is of the greatest importance to the progress and unity of our empire.

FLY-WHEEL POWER OF MOTORS.

By E. K. SCOTT.

In driving certain types of machines individually by electric power, the question of fly-wheel effort comes prominently forward. As usually made, the fly-wheel power of small electric motors is very low, and if they are coupled up to machines which have been previously driven by a long line of shafting crowded with wheels, pulleys, belts, &c., it may be found that the change is not quite satisfactory.

A class of machines in which this is important are the "doughers" and "breakers" used in biscuit making. These machines have heavy rolls requiring to be constantly reversed, and very considerable effort is required each time the dough enters the rollers. To buy an ordinary motor and reversing switch off the shelf, as it were, and connect it up by gearing to such machinery without any thought as to the fly-wheel power, &c., is risking a failure.

Planing machines present a somewhat similar problem, and it has been found best to drive them by a motor constantly running in one direction and arranged with some amount of fly-wheel power.

Pulping machines, used in paper making, also require motors with a good deal of fly-wheel effort in order to keep up the speed when any knotty material enters the roller teeth.*

Some machines, such as shears, punching machines, stone breakers, &c., are themselves fitted with heavy fly-wheels, and as no reversal of the motor is required, they can be driven in a fairly satisfactory manner by a stock size machine dropped down alongside. On the other hand, the coupling up of a motor to a set of Callender rolls, which need extremely slow and steady variations of speed as well as reversal of the direction of rotation, requires some little thinking out.

The writer might go on giving particulars of special cases, but it will be seen from the above that although there is nothing *very* complicated about it, some little thought and judgment is required in applying electricity to driving machines.

Motors as at present made, and especially the smaller sizes, ½, 1, 1½, 2, 3, and 4 H.P., are certainly lacking in weight of the rotating parts. The tendency all along has been to cut down the size of the armature, &c., to the smallest possible dimensions. One often sees a heavy fly-wheel fitted on a machine having a ridiculously small armature. Surely it would have been better and cheaper to have put the weight into the armature, &c., right away. Any motor, whatever it is required for, is all the better for having plenty of fly-wheel effort.

This need of weight in the armatures, &c., of small motors raises anew the suggestion of using iron wire for the conductors. At the present moment the problem stands somewhat as follows:—Individual motor-driving is acknowledged to be the correct method of applying electric power to machinery; for instance, instead of one 20-H.P. motor driving a group of 10 machines, there should be 10 motors each of 2 H.P. Now, the majority of machines are comparatively slow running, and one or two trains of gear wheels are required from the motor spindle. Gearing does not work altogether satisfactorily at high speeds; besides, the less there is, the more efficient the combination. The tendency is, therefore, to follow traction practice and have slow speed motors with only a single reduction gear.

Now it happens that the most convenient way to get slow speed is to have four poles instead of two, and as the usual voltage is 220 or 440, the sizes of the armature conductors come out excessively small. A 2-H.P. 220-volt four-pole motor, for example, only requires about 8 amperes at its terminals, giving, say, 2 amperes through the armature conductors, whilst a 440-volt motor will actually have only 1 ampere flowing through the armature conductors. It will readily be seen that to wind an armature with the theoretical size wire for such trifling currents, is both difficult and expensive. As a matter of fact, No. 18 S.W.G. wire is really the smallest size which is mechanically safe, and this has an area many times larger than what is really required. Substituting iron wire at once gets over this mechanical difficulty, because, for equal conductivity, the wire is about two and a half times the diameter of copper wire.

There is another advantage in using iron wire. Small motors are principally uneconomical because the armature winding with its insulation, binding, &c., occupies such a relatively large amount of space; in other words, the air gap, and therefore the exciting walls, are excessive. Iron conductors being also magnetic get over this difficulty in a delightfully simple way, and the reduction of the air-gaps to a mere mechanical clearance carries with it the further advantage that the pole covers may be brought much nearer together without undue magnetic leakage, thus rendering a larger proportion of the armature circumference useful.

As the area of iron wire is six times the area of copper, there is, of course, more space taken up, and the total weight of the revolving mass is considerably heavier, but as has been pointed out above, this is a distinct advantage for motor work.

Fly-wheel power is what the small motor, as at present made, sadly lacks.

The question of cost comes secondary to turning out a satisfactory machine, but in this also the iron would probably score for voltages of 220 and upwards. For one thing, the cotton covering would be cheaper, and the wire much easier to handle, which, seeing that the cost of small machines mostly goes in labour, is a consideration.

Those who have not thought over the matter may be inclined to scoff at the idea of using iron wire conductors, but there is undoubtedly much to be said in favour of the change for motors of less than 3 or 4 H.P. at 220 and especially 440 volts. This latter pressure is likely to be much used in the future, but as matters stand at present it is practically impossible to build the smaller motors for this pressure.

* It is interesting to note that as the top roller takes the power, and is, at the same time, always on the rise and fall, according to the condition of the material passing through the rollers, the problem presented by the gearing is practically the same as that of a tramcar motor.

LIMITED ELECTRIC STATIONS.*

By ALTON D. ADAMS.

A central station of low first cost and high operative efficiency, to serve a limited area, is a common problem in electrical design. Hundreds and thousands of small cities and towns have nearly their entire business interests within a radius of one-half mile from a central point, and the possible demand for electric light and power is such as to warrant only a very moderate outlay. When the fact that very small central stations, in places similar to the above, run at a loss is held in mind, the necessity for careful selection of equipment is evident, and the designing engineer must decide a variety of questions with no little skill, to insure a financially successful plant.

The station under consideration would be required to operate from 18 to 24 hours per day, and this fact has an important bearing on the average efficiency of electrical equipment, when it is considered that the maximum load of lamps on a central station usually continues but two or three hours per day, and the load during the remainder of each

* *American Electrician.*

Digitized by Google

day is but a small part of the maximum amount, since the variation of losses inside and out of the station does not necessarily rise and fall in the same ratio as the load.

There are two main classes of electric generators, either of which may be used to operate incandescent lamps, namely, those generators intended to connect directly with the lamps, through the proper conductors, and those intended to connect with transformers, but having no electrical connection with the lamps. Generators connected directly with the lamps are limited in electric pressure or volts to the voltage of the lamps, plus the small loss of pressure allowed in the connecting wires. Generators for connection to transformers are of the alternating current type, and may be of any desired voltage, as the proper voltage for lamps is supplied by a suitable transformer.

Alternating current generators with transformers have been much more frequently selected for stations like the above than have the type of generators suitable for direct connection to the lamps, for two reasons—first, because the weight of conductors to supply a given number of lamps at a fixed distance and per cent. of loss varies universely as the square of the volts or electric pressure at which the energy is supplied; and, secondly, because until several years ago the highest practical electric pressure at which lamps could regularly be had was about 110 volts. At 110 volts the weight and cost of conductors is very large compared with other parts of the equipment, even on distances so short as one-half mile; while a voltage may readily be selected for alternating current generators at 1,000 or 2,000 volts, which will reduce the weight and cost of conductors to a very low figure.

The great saving in conductors made possible by the transformer system at 1,000 volts as compared with the 110-volt system is shown by the ratio $(110)^2 \div (1{,}000)^2 = 0{\cdot}0121$ in weights of conductors for the 1,000-volt system, compared with the weights for the 110-volt system.

A third method of distribution, known as the three-wire system, by which the station voltage could be increased to from 220 to 250 volts, with 110-volt lamps, has also been possible, but being patented its use has been mostly limited to stations buying their electrical machinery of a certain company. Considering at first what are called the outside wires of the three-wire system, the weights of conductors required for it, compared with those of the 1,000-volt transformer system are shown by the ration $(1{,}000)^2 \div (250)^2 = 16$, that is, sixteen times the weight of conductors is required for the two outside wires of the three-wire system as for the 1,000-volt system; but the third or neutral wire of the three-wire system is usually made of the same size as each of the other two, so that the total weight of conductors for the system becomes $16 \times 1{\cdot}5 = 24$ times the weight necessary for the 1,000-volt system.

The 125-volt system, connecting dynamos directly with lamps, has been used in a few small stations, serving very limited areas; the 250-volt three-wire system has been very largely used by stations buying their electrical machinery from a certain company, and its use would have been much more extensive were it not for the patent limitations above named.

Reasons for the continued use of the three-wire system in many cases, and of the 125-volt system in a few stations serving a very small area, are found in the cost of transformers, which must be added to that of conductors for the 1,000-volt alternating system, and in the low all day efficiency of the transformer system.

The low all day efficiency of transformers is due to the fact that a large part of the loss in a transformer remains constant, so long as it is connected to the supply of current, no matter how small its load of lamps, or whether it is operating any lamps at all.

Now, as even quite small central stations must operate from 18 to 24 hours per day, and as most of the transformers have only a very light load or no load during most of the time, the constant transformer losses materially reduce the average efficiency. In spite of the cost of transformers and their low average efficiency under working conditions, the transformer system seemed destined to do the great bulk of incandescent lighting from small and medium central stations, had the maximum practical pressure for incandescent lamps remained at about 110 volts, but happily this is not the case.

For several years back incandescent lamps for from 220 to 240 volts pressure have been regularly on the market, and their advent, marking a new era in central station design, necessitates reconsideration of the advantages of direct and transformer systems of incandescent lighting. Allowing a moderate pressure for the loss in conductors, the new high volt lamp permits the same station pressure as the three-wire system—that is, about 250 volts—and therefore requires the same relative amount of conductors, compared with the 1,000-volt transformer systems, as is necessary for the two outside wires of the three-wire system, which amount, as computed above, is 16 times that at 1,000 volts. It is evident from the above that a fair decision between the merits of a transformer and a direct system for any given case, must rest largely on the relation between the sum of costs for conductors and transformers for an alternating system, and of conductors alone for a system of direct connection from dynamos to lamps, and also on the operative efficiencies of the two systems. The cost of conductors for the 220-volt lamp is to the cost of conductors for the 110-volt lamp on the two-wire system as $(110)^2 \div (220)^2 = \frac{1}{4}$; that is, but one-quarter of the weight in conductors is required, and as the three-wire system makes necessary a third wire, equal in weight to each of the other two, the 250-volt two-wire system requires only two-thirds the weight of conductors necessary for the three-wire system, with 110-volt lamps.

To determine, therefore, the best system under the usual circumstances, and free from chances of patent litigation, comparison should be made between the 250-volt two-wire and the 1,000-volt or 2,000-volt transformer system.

For purposes of comparison, the cost of electric generators for a given capacity may be taken as the same for either system, though the price of low pressure generators for the direct work would usually be somewhat lower than those of high pressure for use with transformers. To reach a correct decision as to the merits of heavy conductors alone on one side, and light weight conductors plus transformers on the other, each transmission system should be designed to operate at the same average efficiency during the entire daily run, or at least at some definite efficiency, so that due allowance may be made for difference in efficiencies if any exists. In places of moderate size, the average capacity of transformers which can economically be used is quite small, as individual users usually require but few lamps, and if more than two or three consumers are supplied from the same transformer, the cost of the low pressure wires to lamps becomes too great.

In a plant of moderate size, using transformers, lamps may be assumed to be divided equally between those of 40, 60 and 100 lamps capacity of 16 nominal candle-power each, and the all day efficiencies of these transformers may be fairly taken at 84, 86 and 88 per cent. respectively.

The average all day efficiencies of above transformers will therefore be $(84 + 86 + 88) \div 3 = 86$ per cent. of the energy delivered to them.

Consider now the cost of conductors on the 220-volt lamp system, and of conductors and transformers on the 1,000-volt alternating system to supply 1,000 16-c.p. lamps, taking 55 watts each and grouped at 2,500 feet from the station.

The maximum loss in conductors for the direct system at full load may be taken at 14 per cent., or the same as the average all day loss of transformers, although the maximum loss will result in a much lower average loss. With a loss of 14 per cent. in conductors and 220 volts at the lamps, the volts at the dynamos must be $220 \div 86 = 255{\cdot}8$ and the pressure expended in conductors $255{\cdot}8 - 220 = 35{\cdot}8$ volts. 1,000 55-watt lamps consume 55,000 watts, and at 220 volts the amperes must be $55{,}000 \div 220 = 250$.

The area of copper conductors to transmit 250 amperes through 5,000 feet of its length with a drop in pressure of 35·8 volts, taking 11 ohms as resistance of a mil-foot of copper, is found by the formula for circular mils as follows:—

$$C\,M = \frac{11 \times 250 \times 2{,}500 \times 2}{35{\cdot}8}$$

Therefore, circular mils = 384,070. The weight of a 384,070 circular mil conductor, insulated, and 5,000 feet long, is about $1{,}308 \times 5 = 6{,}540$ lbs., the weight being about 1,308 lbs. per 1,000 feet, and its cost, at 20 cents per lb. is $6{,}540 \times {\cdot}20 = \$1{,}308.00$.

Coming now to the alternating system with transformers,

E

Digitized by Google

the average cost of small transformers may be fairly taken at $1.25 per lamp capacity, so that their total cost for 1,000 lamp capacity is 1,000 × 1.25 = $1,250.00.

As the average efficiency of transformers for all-day service is quite low—86 per cent. in this case—it is desirable to maintain a very high efficiency of conductors in the alternating system, so that the total efficiency of transmission may be as high as practicable. Were there no loss whatever in the conductors between alternating generators and transformers, the efficiency of the system would be lower than that of the direct system on the loss assumed in the direct conductors, since while this loss was taken at its maximum as equal to the average loss in transformers, its average amount will be much below the maximum, and therefore below the average loss in transformers.

It should therefore be noted that while in alternating current transmission with transformers the highest efficiency is at full load, and efficiency drops as load decreases, just as the opposite of this is true for the direct system of transmission, in which the lowest efficiency of conductors is at full load, and the efficiency rises as the load decreases.

In consideration of above facts the loss in alternating current conductors for above case may be taken at 2 per cent. for full load, and be less than this at average load.

As 1,000 55-watt lamps consume 55,000 watts when all lighted, the watts then delivered to transformers, taking their average full load efficiency at 95 per cent., will be 55,000 ÷ 95 = 57,893 watts. To transmit this power over 5,000 feet of conductors at a loss in them of 2 per cent. and 1,000 effective volts at transformer terminals requires about 2,900 lbs. of insulated conductors, which at 20 cents per lb. cost 2,900 × ·20 = $580.00. Adding the cost of transformers found above at $1,250 and the $580. just found for conductors between generators and transformers gives a total of $1,830.00, but this does not include any charge for conductors to connect transformers with the lamps on consumers' premises.

With 100-volt lamps a loss of 2 per cent. in wires to transformers, and an average length of 200 feet for these wires, the 55,000 watts consumed by all the lamps require for their transmission about 426 lbs. of insulated conductor, which, at 20 cents per lb., amounts to $85.32, making, with the $1,830 above, a total of $1,915 for the alternating current transmission system.

The cost of transmission system for the direct current in above case was found to be $1,308, so that the alternating system costs 1,915 ÷ 1,308 = 1·46 times the direct system of transmission under the fair assumptions above, for a concentrated load at one-half mile from the station. Had the direct system of transmission been designed for the same average efficiency as the alternating, its cost for conductors would have been much less than the $1,308 above found, and the increased cost of alternating system over the direct would therefore have been much greater.

Having noted, however, the increased cost of the alternating system for what may be considered ordinary design in each case, it will now be interesting to compare the efficiency of the two systems. The average efficiency of the transformers in above case is 86 per cent., and for the average loss in the two sets of alternating current conductors, with 2 per cent. loss in each at maximum load, about 2 per cent. should be allowed as average loss, making the total transmission efficiency of the system about 83 per cent. on the average.

The loss in conductors of the direct system varies directly as the load on them, and will therefore be 14 per cent. at full load, 7 per cent. at half load, and 3·5 per cent. at one-quarter load, and 1·75 per cent. at one-eighth load, of the energy transmitted at each stage of load. It is a fair assumption that full load will last during two-tenths, half load during two-tenths, quarter load during two-tenths, and eighth load during five-tenths of the time, in which case the total transmitted energy conveyed at each stage of load may be taken as follows:—At full load, 1 × ·2 = ·2; at half load, ·5 × ·2 = ·1; at one-quarter load, ·25 × ·2 = ·05; at eighth load, ·125 × ·4 = ·05; the sum of which is ·2 × ·1 + ·05 + ·05 = ·4.

The part of total energy transmitted at each stage of load will therefore be, for full load, ·2 ÷ ·4 = ·5; for half load, ·1 ÷ ·4 = ·25; for quarter load, ·05 ÷ ·4 = ·125; and for eighth load, ·05 ÷ ·4 = ·125.

Applying per cents. of loss for the several stages of load, the per cents. of total energy lost at each stage of load are: Full load, ·5 × ·14 = ·07; half load, ·25 × ·07 = ·0175; quarter load, ·125 × ·035 = ·0043; and eighth load, ·125 × ·175 = ·00218. The sum of these fractions of total energy is ·094, or 9·4 per cent., so that the average transmission efficiency of the direct system is 90 6 per cent. For above case, then, the cost of transmission devices is not only 1·46 times as great with the alternating as with the direct system, but the average transmission loss with the alternating system is 17 ÷ 9 4 = 1·8 times that with the direct.

The facts illustrated by the above figures seem ample to warrant the growing preference for direct electric distribution over moderate areas.

CORRESPONDENCE.

Renewable Lamp Company.

I have read your remarks in your issue dated August 20th, in which you state that "we are afraid we cannot congratulate the Renewable Lamp Company on the lines adopted by their advocates."

I have not the slightest knowledge of anybody who has taken it upon themselves to write letters on this question, and I must disclaim any association with them whatever, and with their discussion.

I have no intention of discussing this matter in the public press, considering that it is quite unnecessary; but for your information and for that of your readers, I may tell you that the works are being equipped in Shoreditch on a large scale, the various appointments of officials have been made, contracts are also being entered into with local authorities, railway companies, theatres, hotels and clubs, &c., and you may rest assured that the activity being thrown into this matter will make it such a live concern that there will be obviously no need for any discussion.

If you will kindly let the question rest, it is a very short time to seeing the lamp thoroughly and practically demonstrated and in general use, which is better than all anticipated discussion.

"The Value of Electrical Treatment."

My attention has been drawn to a review of the above work which has recently appeared in your columns, and I wish to protest, in the strongest manner, against the tone in which that article is written. Fair criticism must be welcome to every sensible man; but mud-throwing should not be allowed in the pages of a professional journal. Your reviewer, however, has thrown mud, by comparing me with a notorious quack and impostor.

Allow me to say that the conclusions at which I have arrived concerning the medical uses of electricity, and to which your reviewer has taken exception, are the outcome of upwards of 40 years' extensive special experience, both in hospital and private practice. They are no phantasmagoria, but have been forced upon me by what I have observed clinically over and over again, and year after year, and they may be verified by anyone who will take the trouble of working conscientiously at this subject. That portion of my work which relates to the use of electricity as a general nervine tonic, and its effects in reducing or removing the infirmities of old age, and which seems to have excited the special ire of your reviewer, has been favourably received by the greatest authorities abroad, such as Prof. E. Von Leyden, of the University of Berlin, Messrs. Trijier & Apostoli, of Paris; Prof. Domner, of the University of Lille, and many others; and has excited the greatest interest and attention in all parts of Europe and America. It is in consequence of it that I have been requested by the committee of the forthcoming International Congress of Electro-therapeutists, which will be held in

Digitized by Google

Paris, in July, 1900, and which is being organised by the Société Française d' Electrothérapie, to give an address on the medical use of galvanism and faradism, and to open the discussion on it on that occasion. This shows as well as anything could, that those best qualified to judge, respect my teaching on that subject.

I feel convinced that my therapeutical discoveries, although they may appear startling to those unacquainted with the matter, will in 10 or 20 years' time be utilised by the entire medical profession, as a mere matter of course. An author on a special subject, who is in advance of his time, must occasionally pay the penalty for this, by receiving obloquy instead of praise; but I confess that I was not prepared, after such a long professional record as I lay claim to, for an onslaught which I consider most spiteful, if not actually libellous, and of which I trust and believe that he who has made it, will, on reflection, be heartily ashamed.

I request that you will insert this disclaimer in your next impression, and am,

Julius Altbaus, M.D.

Stresses in Steam Engines for Electric Traction.

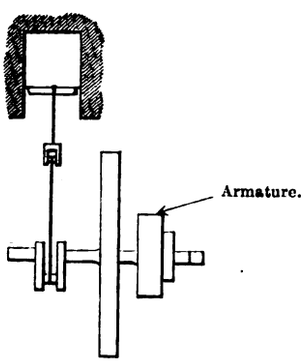
The able article on this subject in your issue of yesterday will serve as an incentive to thrash this matter out rather more fully than has, so far as I am aware, been done at present. It is, however, rather unfortunate that, after maintaining his case so well as regards the stresses on the crank-shaft on the *engine* side of the fly-wheel, you contributor should, as it were, at the last moment, rather give himself away by the manner in which he tackles the stresses arising on the *dynamo* side of the fly-wheel.

What I take exception to—and I do so very reluctantly, as I would much prefer to accept the solution of your contributor—is the statement that: "a traction generator has no mechanical or material inertia to overcome when a sudden accession of load is put upon it, and *this fact limits the maximum possible stress in the shaft to double the ordinary.*"

May I suggest to your contributor that it is *not* this fact which limits the possible stress, but, as I shall hope to show, simply and solely the question of the time-lag of the generator and the rapidity of action of the automatic cut-outs in the station.

Leaving for the moment, however, the question of the cut-outs, your contributor seems to have forgotten his remark, made earlier in his article, in which he acknowledged that there *were* "resistances due to the revolution of an armature in a medium resembling a fluid with a variable viscosity."

The point at issue is this: Is it not conceivable that the drag exercised by the field on the periphery of the armature (and which may be likened to the sudden application of an



extremely powerful brake) may, under certain conditions, attain proportions so considerable as to entirely outweigh questions of the inertia of the armature?

For clearness sake let me again repeat that I am now only considering the stresses on the shaft connecting the armature with the fly-wheel, and *not* those on the engine side of the fly-wheel.

This being so, what are the conditions? The fly-wheel and the armature are running at the normal speed; a short circuit occurs on the line; a rush of current of perhaps several thousands per cent. above the normal current (due to 500 volts acting through a trifling resistance); a sudden increase of the retarding armature torque, amounting—even assuming the field remained unaltered—to, in all probability, at least *one thousand per cent.* above the normal.

The result is equivalent to the sudden application to the armature of an immensely powerful brake, while the fly-wheel goes merrily on its way.

Your contributor, however, ignores this action. All I can say is that, though I have perhaps overstated my case as regards quantities, yet I can adduce from personal knowledge an instance where *two* traction dynamos, designed to absorb approximately 200 B.H.P. apiece, had their 5-inch shafts sheared off at the point where one would expect, from the above considerations, that such an accident would occur, and this *within three weeks* of one another.

The third was only saved, if I remember rightly, by reducing the weight of the fly-wheel by turning it down.

I am sorry that, for want of further time, I cannot now go into the question of why everything hangs on the number, arrangement, and rapidity of action of the automatic cut-outs; but the inference is a fairly obvious one, and I will close here, in the hope that I have explained my grounds for differing with your contributor's conclusions.

A. M. Taylor.

The only difference between myself and Mr. Taylor, is one of meanings. By mechanical or material inertia, I mean such inertia as, in a marine engine, is represented by the sudden putting into motion or rapid acceleration of a mass of inert water. The intensity of stress produced by such action is measured by the mass put into motion, and the time occupied in the process. The shorter the time the greater the stress, and given sufficient velocity acquired, and short enough time, a very little weight may induce enormous stresses. Now, the action of a sudden accession of current in a generator, can at its worst only represent a double stress. It is like the application of a brake to a fly-wheel, but it is not like the putting in of a claw-coupling attached to another and stationary fly-wheel. Now if we allow, and Mr. Taylor does apparently allow, this equivalent braking action, the whole question is narrowed down to the pressure that can be put upon the brake lever. I did *not* overlook this action, but merely stated that the stress due to it could not exceed double that due to the maximum current ordinarily generated. By *ordinary*, I mean the current beyond which the circuit breaker will not permit any addition.

If there were no circuit breaker, the braking action might be enormous, but I have assumed circuit breakers without which safeguard I fear stresses would be incalculable, and I should as soon make an engine without a fly-wheel as a traction system without a cut-out, and I have never seen any traction station without circuit breakers. Perhaps if Mr. Taylor will read the article again, assuming cut-outs, he will be in agreement with me. If not, will he state whether there is, or is not, reliance to be placed on circuit breakers. Does he consider these so slow in action that they permit the passage of such severe currents as to render them practically useless. Let me put Mr. Taylor's 1,000 per cent. of torque and my own coefficient of two for sudden loading into practice as follows:—

I will take it that Mr. Parshall's engine has a torque average equal to a 21·4 shaft with a 12-inch hole in it. This is smaller than Mr. Parshall's dimensions point to. Then 1,000 per cent. × 2 = 20 fold as the indicated ratio of strength in the shaft between fly-wheel and generator. The shaft for this must be 54·6 inches diameter!!! with a 12-inch hole, and Mr. Parshall's 32-inch shaft must twist off like lead. It is far too weak. Now, if Mr. Taylor's assumption is probable, as he says it is, it must be clear that Mr. Parshall places an enormous reliance on circuit breakers, so much so as to design or accept shaft diameters only half what they should be. For my own part, I have accepted the circuit breaker as being capable of preventing current in excess of a fixed maximum, and it is this fixed maximum which I would double to allow for sudden application. From his letter, I judge that Mr. Taylor has more to say, and I, for one, would be glad to have him say it. Will he tell us the rapidity of action of a circuit breaker, and

Digitized by Google

whether it will do what I expect it to do? The whole safety of a traction station hinges on this, and without circuit breakers I fail to see what limit of sizes can be fixed on for a shaft.

Let us first agree on terms. By ordinary stress is meant the limit fixed by circuit breaker; by material inertia the energy of acceleration of a mass. My contention is, that the stress in the generator shaft is limited *within* double this ordinary, just as a beam deflects doubly as much under a suddenly applied load.

Will Mr. Taylor also state, can a short circuit produce an absolutely instantaneous sudden rush of current, or is there a certain duration of time in building up? Why are some circuit breakers fitted with a retarder to prevent them acting from mere passing flushes? These retarders are dangerous, for they prevent rapid action when this is necessary. If it is established that a circuit breaker will prevent excess of current, then there can be no abnormal or incalculable shaft stresses. If, on the other hand, they are not reliable, then Mr. Parshall's heavy shafts are mere temporary spindles.

Finally, Mr. Taylor adduces two cases from personal knowledge, where some 5-inch shafts were twisted off. Will he tell us, first, whether there were any circuit breakers; and, secondly, at what speed these shafts were running, for I find that if they were running at 180 revolutions, they correspond in strength with a solid shaft on a 4,000 H.P. generator at 90 revolutions per minute of 17 inches diameter, and a hollow shaft with a 12-inch hole of less than 19 inches diameter. It looks rather as though these 5-inch shafts were weak to begin with.

The Writer of the Article.

ECONOMY IN USE OF SUPERHEATED STEAM.

Mr. R. S. Hale is well known as a steam engineer in America, and his remarks on superheated steam in the *Engineering Magazine* are entitled to consideration. He anticipates the spread of superheating to England and America. A few years ago the practice seemed to have fairly recommenced in England, but we seem of late to have heard very little on the subject. The methods of superheating are discussed and enumerated. There are three usual methods.

(*a*) To place the superheater in the flue entirely behind the boiler. This effects a small gain and boiler efficiency, but less than can be secured from a flue feed-heater or economiser, but it cannot be very effective in adding a serious degree of superheat, for the waste gases have a temperature nothing much above that of the steam itself, unless when the boiler is forced, when a superheater may be itself effective, and also a considerable aid to the boilers.

(*b*) The superheater may have its own special furnace. Heat so applied is usefully applied, but the separate furnace is difficult of satisfactory application, and the total efficiency for the *production* of steam will be diminished.

(*c*) By placing the superheater in the path of the gases earlier than the waste flue, higher temperature is secured with efficient and considerable superheat. Nothing in the system prevents the application of the economiser at a later point, and generally the system seems to commend itself to Mr. Hale. It will be remembered that this is the system of which a good deal was said a few years ago in connection with the McPhail & Simpson superheater. But Mr. Hale appears only to know the system as applied on the Continent.

He says that carefully kept records show that the net result is equivalent to an addition of so much of the heating surface. 500 feet of superheater surface, he considers, would be equal, say, to 250 feet of more efficient water-cooled heating surface. If we recollect rightly, the experience of the McPhail system appeared to point to very effective surface if the steam was wet. A boiler could be forced until it primed, and the superheater dealt with the priming, and a water-tube boiler could thus be safely pushed to double and even treble its ordinary output, the superheater giving dry steam. Further, this position of superheater gives very even results, and it is fairly safe.

Still, an equal surface in an economiser will do more than a superheater, says Mr. Hale. Here, of course, he is speaking only of the generation of the steam, not of its possibly more efficient use. There are certain losses which are increased by the use of superheated steam, namely, those of radiation and leakage. The radiation losses increased with the superheat. This may be so, and still it is advantageous from a using point of view that steam should arrive dry at an engine. Saturated steam can never arrive dry. Superheated steam may.

Being bulky, superheated steam will suffer a greater fall of pressure than saturated steam because it must travel quicker. But is this quite true. It will travel faster with greater ease, for it will not be retarded by inert particles of water, and the velocity of a current of steam is reduced by its load of water. We quite agree, however, that steam pipes are too big in many cases. A 12-inch main is seen with 6-inch engine branches. Probably better results will be secured by reversing this, and putting 12-inch engine branches from a 6-inch main. A commonly-neglected point in steam pipe designing is that the flow of high pressure steam is very much greater than the flow of low pressure steam. The flow corresponds with the absolute pressure, but the production of a boiler is the same at all pressures. It is the same in weight but the volume differs, and no matter what the pressure the same volume of steam will flow through a given orifice. Obviously, therefore, the steam pipe of a high pressure boiler may be made much smaller than that of low pressure boilers of equal size.

Moreover, with early cut off engines the steam pipe may be correspondingly less than for long admission, provided that the sudden demand of steam at admission be provided for by the use of a receiver close up to the engine. A third loss of steam is leakage, Even when joints appear tight, there may be a good deal of steam leakage going on. Some tests of leakage have given the following figures:—

Mill	5 to 16 per cent.
Electric plant	2½ to 7 „
Steamship	1½ to 10 „
Waterworks	2½ per cent.

Suppose a plant to be worked only half of its capacity, then the leakage percentage will be doubled. As the temperature of superheating varies a good deal, so will the movement of the steam pipes be increased, and this will probably increase this percentage of leakage.

Coming to the engine, however, there is a clear net saving of 20 per cent. down to 10 per cent., and the use of mineral oils seems to have solved the problem of lubrication. Recapitulating, we find:—(1) A slight gain in the boiler; (2) an increased loss in the steam pipes; (3) a large economy in the engine.

While in favour of the form (*c*) of superheater, it is pointed out that where a long distance intervenes between the boiler and engine, the separate furnace may prove superior. Thus, if a short pipe be assumed, the following figures obtain in a typical instance:—

Gain at boiler...	2 per cent
„ „ engine	10 to 20 per cent.
Extra radiation loss	1 „ „
„ leakage „	3 „ „
Fall of pressure „	½ „ „
Net gain	7½ to 17½ „ „

Let now the length of pipes be doubled and the plant be assumed to work at only one-third its capacity.

Gain at boiler	2 per cent.
„ „ engine	10 to 20 per cent.
Extra radiation loss	6 „ „
„ leakage „	18 „ „
„ fall of pressure loss	½ „ „
Net loss, 2½ to 12½.	

In such a case, probably, superheating might pay if done near the engine. It will also pay to equip all boilers with superheaters if it is found to pay when some of them only are fitted.

Mr. Hale's remarks may be carefully considered. They point to the necessity of more careful steam pipe design. Pipe joints are one of the details of high pressure steam practice that are very unsatisfactory. A good steam pipe joint is needed. The lack of one is one of the chief obstructions to the economy of high pressure steam. Yet it seems almost as unattainable as a really strong half-inch bolt.

THE UTILISATION OF WASTE HEAT FROM FLUE GASES.

It is only comparatively recently that American practice has embraced the economiser or flue-feed heater, but having done so American engineers have gone a step further than ourselves, who have used the economiser half a century, for, to an extent unknown here, the system of fan draught has been employed for land boilers, whereas it is almost restricted to marine work in Europe. Yet it is 20 years or more since fan draught was used in a Yorkshire mill, the fans being placed at the rear of the boilers to draw away the products of combustion and discharge them to a chimney which only reached to the roof level of the factory.

The American line steamship pier at New York has its boilers fitted for fan-induced draught, and the plant is described in the *American Electrician*, which premises that with an air temperature of 60° and a chimney temperature of 500, a chimney of 100 feet will produce a sufficient draught, but that a chimney 175 feet will be required to produce the same draught with gases of 250°. This, of course, is just the reverse of a fan which is more effective with low than with high temperatures, and it is where temperatures are low, and in order that they may be low that a fan is used. A fan is more certain than a chimney, for its speed can be regulated to give a desired intensity. Unlike a chimney, and in direct opposition thereto, a fan will probably work better when the barometer is low.

An economiser is not merely an obstruction to the draught, but, by cooling the gases, reduces their draught-producing power, and a limit is put to any desired further temperature reduction. Everything points to the fan in place of the chimney. In a power plant of 1,000 H.P. at least 300 H.P. is rejected at the chimney in ordinary cases, and in good practice 1,000 H.P. at the engines must represent nearly 200 thrown into the chimney. Assume that 100 H.P. can be saved, is it not obvious that the 100 H.P. saved is very much greater

Digitized by Google

than the power absorbed by a fan. Our contemporary sets down the ratio between fan power and chimney power as 1 : 75.

With gases entering an economiser at 526°, leaving at 269° and heating the feed water from 150° to 297°, a saving of 14·64 per cent. may be effected. Besides feed heaters, there are air heaters which will effect economy, but such things must not be carried too far. Americans in many cases seem to take it for granted that the use of an economiser necessitates a fan draught. This view has not been accepted in England where, for years, economisers have been employed with chimneys of 200 feet in power plants, giving results of 1·75 lbs. of coal per I.H.P. In America, however, many years since, Mr. Hoadley made tests where chimney gases were reduced to 162°, which represents only about 5 per cent. of heat loss. In Howden's system, the chimney gases are reduced to 574°, and the air supply is raised to 263°, but we suppose there was no economiser in this quoted case. In the particular instance under review, at the steamship pier the fan outlet has a temperature of 456°, and the air is heated to 315° when burning 41 26 lbs. of fuel per square foot of grate surface.

These results, of course, do not compare with those obtained from economisers; these sometimes reduce the gases to 350°, or even as above to below 300°, but possibly the economiser and the air heater could be both employed with advantage. Chimney draught seems never to have been applied with any satisfactory results where the air supply was heated. Something more is needed to force the air in sufficient volume to the fires. Theoretically, a saving is possible, but as air expands with heat its efficacy is spoiled, and it is only since fan draught has been employed that the regenerative system has become practically useful. In the apparatus at the steamboat pier the furnace air is simply drawn through nests of tubes around which pass the wasted gases on their way to the fan. Looked upon merely as a draught producer, the fan is a wasteful implement, unless accompanied by corresponding decrease of waste gas temperature. It should never replace an existing *sufficient* chimney, unless there is at the same time applied some means of using the waste heat. But given such means, a fan may be employed with great economy. So long as the chimney is there it need not be removed. It will always, if big enough in area, help the fan and save power in the fan engine. But if its site is wanted, the chimney may be destroyed, and it may be replaced by a simple low iron stack. It is a good plan to provide ducts, so that the fan may draw its air from the engine room to any desired extent.

Anglo-German Competition in Russia.—The British Consul-General at St. Petersburg, in a recent report, shows that Germany is competing with us for the foreign trade of Russia with great success. He thinks the further development of this successful competition can best be met by greater activity on the part of British manufacturers, who should study previous Consular reports from Russia as to the methods to be employed; but he emphasises the importance of adopting the German system of frequently sending competent agents to Russia. The *Times* quotes the report at some length. It also mentions that a report from our Consul at Moscow says that while the machinery for cotton and flax spinning and weaving continues to be procured from England, mill engines are being got in increasing numbers from Switzerland, boilers from Poland, steam pumps and machine tools from America, and electrical machinery from Germany and Switzerland, though 10 years ago most of these went from England. In view of the ever increasing importance of Moscow, which is now the real commercial capital of Russia, he thinks British manufacturers and capitalists should give it more attention than they do at present.

Annual Outing.—The 14th annual outing of the employés of Mr. G. Stegmann took place on Saturday, 26th ult., when a most enjoyable day was spent on the river, starting from Richmond by steam launch. Lunch was served at Chertsey.

Auction Sale.—Messrs. Fuller, Horsey, Sons & Cassell, are instructed to sell by auction, at H.M. Dockyard, Chatham, on September 28th, at 11.30 o'clock, 10 electric light engines and dynamos, electric cable, gear, &c.

Bankruptcy Proceedings.—In *re* the bankruptcy petition of Henry William Thane, electrical and general engineer, 32, The Hill, Northfleet, near Gravesend. The debtor's summary of affairs show gross liabilities at £144 15s. 9d. The assets include £25 worth of stock-in-trade, and a few pounds are set down for machinery, trade fixtures, &c. There are also a few book debts, and a deficiency is shown of £101 7s. 3d. Debtor states that the cause of his failure is insufficient trade to meet expenses. Nearly the whole of the scheduled debts are with trade creditors.

The first meeting of creditors and the public examination in *re* the failure of S. F. Walker, electrical engineer, Cardiff, are to be held on September 11th and October 3rd respectively, at Cardiff.

Liquidations, Dissolutions, &c.—A meeting of the Northern Counties Electric and Motor Company will be held at Town Hall Chambers, Halifax, on October 4th, to hear an account of the winding up from the liquidator, Mr. J. Robinson.

Messrs. A. S. Jones and J. Ritchie (A. Savory Jones & Co., electrical and mechanical engineers, Oriel Road, Bootle) have dissolved partnership. Mr. Jones attends to debts.

Catalogues.—An illustrated list of electrical novelties and appliances comes to hand from the Ohio Electric Works, Cleveland, Ohio, U.S.A.

The General Electric Company sends us an illustrated list of the "Carsak" primary batteries.

From Messrs. Dick, Kerr & Co., we have received an illustrated circular describing the Solenoid blow-out series parallel controllers which are being used on a number of English electric tram lines, including Blackpool and Fleetwood, Dover, Dublin, Hartlepool, Liverpool Overhead and Waterloo and City Railways, and will be largely employed on the Bolton and Liverpool tramway systems.

Messrs. C. A. Vandervell & Co., of Thorpe Works, North Kensington, send us a set of illustrated price sheets of pocket batteries, portable lamps, cycle lamps, accumulator plates and accessories, measuring instruments, small dynamos and motors, &c.

Change of Name.—The name of the House-to-House Electric Light Supply Company has now been changed to the Brompton and Kensington Electricity Supply Company, Limited, and all communications should be addressed in that manner to Richmond Road, Earl's Court, S.W.

"Combricant."—This is the name of a new lubricant being introduced by the Lubricant Company, of Charles Road, Small Heath, Birmingham. We have received a sample tube of "Combricant," which we understand has been extensively tested on a number of public and private electricity plants with satisfactory results.

Commutator Burnisher.—The Edison & Swan Company sends us a list of its patent "Ediswan" commutator burnisher, which provides a simple means for keeping commutators in a perfectly clean condition. The trouble and inconvenience of "turning up" the uneven surface of a commutator frequently prevent this necessary duty being performed by the attendants of the machine, with the well-known deteriorating results to the commutator. This patent burnisher reduces the expenditure of labour required to a minimum, and the machines can always be run with a smooth and even-surfaced commutator, free from sparking and the consequent

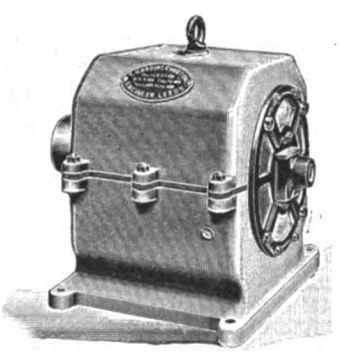
Digitized by Google

increased wear of the brushes. In operation, a strip of emery or polishing cloth, the same width as the burnisher, is cut, and one end inserted under the clip at the front end; it is then turned back under the flexible backing and applied to the commutator. The flexible backing is made in such a manner that it easily adapts itself to the curve of the commutator, but will not fall into depression on the surface. Thus the whole surface is evenly scoured with emery cloth to any degree of roughness required and afterwards polished.

Copper.—The *Financial News* says that movements of copper during August show a reversal of the conditions which obtained during July, a falling-off in the supplies and an increase in consumption resulting in the price of g.m.b.'s and standard copper going up again to £76 15s., at which it stood at the end of June, July having witnessed a decline of 10s. According to Messrs. H. R. Merton & Co.'s statistical circular, the deliveries last month were 18,595 tons, and the supplies 17,965 tons, and the stock now stands at 32,389 tons, a falling off of 630 tons. As compared with July, supplies were 2,377 tons less and deliveries 2,268 tons more.

Correction.—In our last issue we stated that Messrs. Sax, Slatter & Co., Limited, had removed to Basil Street, Sloane Street, S.W., from Foresters' Hall, Clerkenwell. As a matter of fact, the firm in April last, removed *from* Basil Street *to* Foresters' Hall, and the latter is the correct address. We are asked to correct the error as having closed their installation department which was originally carried on at Basil Street, Sloane Street, S.W. Messrs Sax, Slatter & Co., Limited have now ceased to do contracting work, and only carry on their wholesale department at Foresters' Hall, Clerkenwell.

Dynamos and Motors.—Mr. T. Harding Churton, of Leeds, is endeavouring to keep pace with the times by adopting advanced methods of manufacture for dynamos and motors. He is adopting the standardisation method for manufacturing parts, so that they may be in stock whenever required. The necessity for English firms to work on these lines has been many a time shown to be imperative, if they are to hold their own against foreign competition. His list of continuous current dynamo machines and electric motors for electric lighting and transmission work is before us. The con-



tinuous current motors detailed in this list are made to gauge, and they may be fitted with pinions for tooth gearing, or with pulleys for belt driving, or may be made for worm gear to suit requirements. The steel-armoured and enclosed motors, as shown in our illustration, are made with two and four poles, with slotted or plain armatures according to the purpose for which they are intended. They are claimed to be substantially reliably made, and motors of this type running in colliery work have run for six weeks continuously at varying loads. Others have been run for a long time, fluctuating from no load to full load without sparking. Shunt series and compound wound continuous current dynamos for 100, 140, 200, and 500 volts, are shown and briefly explained in the list, and prices are given. Among the installation contracts which have been recently carried out by Mr. Churton are the following:—An installation comprising two gas engines of 30 B.H.P., and two compound wound dynamos, switchboard, wiring, &c., and 58 arc lamps, for the Leeds Corporation. An installation comprising two dynamos, one of capacity for 1,200 lights, and the other for 150 lights, switchboard and wiring, &c., for Messrs. J. Hepworth & Son, Limited, Clothing Factory, Leeds. Electric pumping plant, consisting of 10-H.P. dynamo and motor working at 400 volts, the pump being about a mile distant from the dynamo; switchboard, insulated cables, gearing, &c.; electric lighting installation, 150-light dynamo, &c., for the Newmarket Haigh Moor Colliery Company, Oulton, near Leeds. Installation for lighting surface and pit of the Monk Bretton Colliery, near Barnsley, with about 150 lamps, dynamo, switchboard, &c. The dynamo here has worked day and night without a stop for six weeks together. A second dynamo has been recently supplied as stand-by.

Educational Notices.—The syllabus of lectures in the Engineering Department at the City of London College, Moorfields, under Prof. H. Adams, has been issued; also the complete syllabus of day and evening classes at the College. The new term commences on Monday September 25th.

The new session in Architecture, Building Construction, &c., at King's College, opens in October, and a syllabus of the day and evening classes can be obtained on application.

Explosion.—It is stated that on Monday an explosion, cause not stated, occurred in the electrical department of the Clydebank Shipyard with somewhat serious results.

Explosion at Silvertown.—On Tuesday afternoon an explosion occurred at the India-Rubber Company's Works at Silvertown, in an experimenting laboratory, and, in attempting to extinguish the flames, a man named Wood, aged 20, was severely injured by falling through a skylight. Much damage was done.

Fire.—It is stated by Reuter that on 30th ult., in the evening, a serious fire broke out in some large electrical works at La Chapelle Triage, by which the Chapelle and St. Denis railway stations are supplied. Damage was done to the extent of 1,000,000 fr. No one was injured.

Fire Resistance Materials at the Paris Exhibition.—There will be an important collective exhibit at the forthcoming Paris Exhibition, representing the fire resisting materials, system of construction, and appliances of Great Britain. The arrangement of this collective exhibit (the first of its kind) is in the hands of the British Fire Prevention Committee, to whom the Royal Commission has allotted the necessary space gratuitously, recognising the national importance of the idea, and the disinterestedness of the effort being made by the Committee to show what the country can produce in this direction. Mr. Frederick R. Farrow, F.R.I.B.A., chairman of the commercial section of the Committee has kindly undertaken the direction of this collective exhibit, and it has been decided that all applications from all British and Colonial firms to be represented in this national exhibit, must reach the offices of the Committee by October 7th. The Committee itself will exhibit a model of its testing station, specimens of reports, and the like.

Gas Motor Car.—We illustrate herewith a convenient form of gas motor car patented and manufactured by Mr. W. H. Dunkley, of Birmingham. It is intended for two adults, as a phaeton, or for two children and a governess, or one adult. It is driven by a Dunkley gas motor, which is constructed so as to be capable of taking in gas from any ordinary gas pipe, with a gas bag attached, or to work with gas that is generated and made as required, as the car goes

along. The speed is from two to twenty miles per hour; it is 5 feet long, 4 feet 6 inches high; and 2 feet 8 inches wide, permitting it to go through any ordinary doorway and stand in any ordinary room. It weighs about 4½ cwt., has two brakes, can be stopped instantly, and will turn in the narrowest streets, easily controlled by a youth or governess. Freedom from smell, vibration and noise, is claimed, and it is guaranteed fireproof. It would be interesting to hear how the car generates the gas as it goes along.

Hopkinson's Valves.—From Messrs. J. Hopkinson and Co., Limited, of Huddersfield, we have received illustrated catalogues describing the special features of their patent valves, including the patent "Ris" valve, patent isolating valves, and blow-off and scum valves. Each of the lists is well arranged and illustrated, and prices are given.

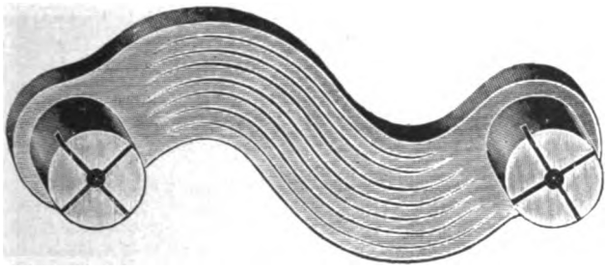
Madras Electric Tramways Company.—Some notes to hand from an Indian newspaper, state that on August 15th a meeting of shareholders in the above company was held to consider the company's position in connection with the threatened bankruptcy proceedings. Mr. Norton, the chairman, explained that the Electric Construction Company, to which the Madras Tramways Company was indebted to the extent of £65,000, had instituted proceedings in London and filed a petition for the liquidation of the Tramway Company. Mr. Norton strongly criticised the gross mismanagement of this magnificent property, for which he held the directors principally responsible, while the shareholders were extremely apathetic and allowed the directors to do practically what they liked. After a lengthy speech it was resolved that a subscription of 4 annas per

Digitized by Google

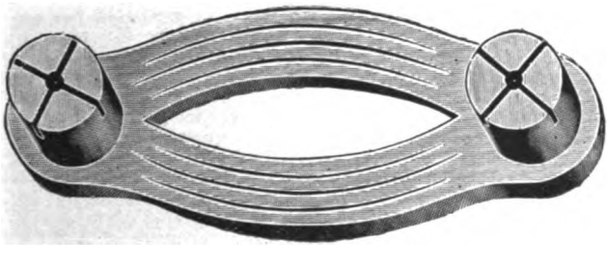
share be levied to meet the legal expenses in London, that the solicitor, Mr. Tasker, should be asked to protect the shareholders' interests in London, that the Committee be authorised to form a company for the purchase of the Madras tramways, and that an issue of 15 lakhs first mortgage debentures on the tramway be made, preference being given to the original shareholders.

New Electrolytic Works.—A Manchester paper says that land has been purchased at Cledford Bridge, Middlewich, by the Parent Electrolytic Company, and a subsidiary company has been formed to manufacture chemicals by a new electrical process.

A New Flexible Rail Bond.—To the various bonds manufactured by Messrs. Felten & Gilleaume, Mulheim-on-Rhine (Germany), and of which large quantities are already in use in the United Kingdom, another new type has been added by them, of which an illustration is given herewith. This new bond has the great advantage over other similar bonds that it is like their ordinary



"Neptune" bond, drop-forged out of one piece of copper, so that there is no weld or joint in them whatever, whereby the highest perfection obtainable is secured. The bond is designed for use in the web of the rail underneath the fishplate, and is fixed in the same method as the "Neptune" bond, viz., by expanding the head of the bond by steel drift pins. In order to provide for the vibrations of



the rails, the body of the bond has been made flexible by means of narrow strips. The sectional area of the body is equal to that of a 6/0 S.W.G. round wire, and the heads are made for ⅞ inch holes in the rails, although other dimensions can be made to order. Messrs. Felten & Gilleaume's price list for copper bonds is now being revised.

South African Electrical Notes.—The current issue of the *British and South African Export Gazette* contains the following items of electrical interest:—

The electric lighting installation ordered by the Langlaagte Exploration and Building Company, for the Mayfair township, Johannesburg, has been delivered.—The electric lighting and power plant of the Globe and Phœnix Gold Mine includes a 90 KW. generator of the four-pole type.—A 15 H.P. motor is also to be installed at an early date.—A complete electric lighting equipment is under order for the Surprise Gold Mine, Rhodesia.—An additional generator for supplying power to the slimes plant is to be erected at the New Primrose Gold Mine.—Considerable orders for telephone plant and material for the East London (Cape Colony) telephone service are in the hands of makers.—The equipment of the Kimberley electric lighting scheme, the contract for which is being carried out by Messrs. Reunert & Lenz, Johannesburg, includes four dynamos, each of 75 KW., 220 volts, and a capacity of 300 amperes. They are being manufactured by the New York General Electric Company. The cables employed will be from the works of Messrs. Johnson & Phillips, Limited.—A Fowler-Hall alternator of 180 KW. (about 240 H.P.) has been erected at the East London Electric Lighting and Tramway Works, and a second is on order. These are to be used for incandescent street and private lighting. The two tramway and arc lamp machines are also of 240 H.P. each.—An order for two dynamos, each capable of an output of 350 KW. as a continuous load, to cost £3,150, has been placed with the South African General Electric Company (Messrs. G. Findlay & Co.) by the Capetown Town Council. The dynamos, we believe, will be of American pattern.

Traction Equipment Contracts.—The London correspondent of the *Street Railway Journal* recently stated that contracts were ready for giving out for the 15-mile light railway to connect Ramsgate and Margate, in which scheme Mr. Wm. Murphy is the moving spirit. It is further stated that the entire contract for the electric equipment of the Rheims (France) Electric Tramway has been taken by the Paris house of Robert W. Blackwell & Co. The same concern has also received the contract for the additional rolling stock required by the Marseilles electric lines.

Trade Announcements.—We observe that the firm of R. W. Blackwell & Co. has now been registered as a limited company under the title of Robert W. Blackwell & Co., Limited. The registered offices are at 39, Victoria Street, Westminster, London, S.W., and the capital £200,000. This company will take over as a going concern, the business of engineers and contractors heretofore carried on by Messrs. Blackwell at 39, Victoria Street, Westminster, London, S.W.; 133, Bermondsey Street, London, S.E.; 20A, Chapel Street, Liverpool; 50, Boulevard Haussmann, Paris; and 120, Liberty Street, New York. The directors of the new company are Robert Winthrop Blackwell, Philip Dawson, and Benjamin Hunting Howell, managing directors (present partners in the firm of Robert W. Blackwell & Co.), Sir Charles E. Howard Vincent, and Francis Henry Barker.

The registered offices of La Capital Tramways Company, Limited, La Capital (Extensions) Tramways Company, Limited, and La Capital Traction and Electric Company, Buenos Ayres, Limited, have been removed to 19, Finsbury Circus, E.C.

Messrs. Wm. Whitehouse & Co., fittings manufacturers, of Birmingham, have appointed Mr. H. Adlam to represent them in London. The showroom will be at 59, Holborn Viaduct as heretofore.

Western Union Telegraphic Code and International Cable Directory.—In the High Court of Justice on Wednesday last week, Mr. Joseph moved before Mr. Justice Cozens-Hardy, sitting as vacation judge, to expunge an entry in the minute book of the International Cable Company, of New York, as registered proprietors of the copyright of the Western Union Telegraphic Code, and that the company should be condemned in costs. Counsel asked that the case might stand over for a week. The Mercantile Publishing Company were the registered proprietors of a code called the "Broomhall's Comprehensive Cypher Code," which was registered in 1895, and was assigned to the Mercantile Publishing Syndicate in January, 1896. In August, 1898, the International Directory Company, of 30, Broadway, New York, U.S.A., were registered as the proprietors of the code, and an action was brought against them in July last with the result that an injunction was granted restraining the publication or importation of this code; he suggested that the matter should stand over. Mr. Bucknill consented. His Lordship ordered that the matter stand over until the second motion day in the next sittings.

ELECTRIC LIGHTING NOTES.

Aberdeen.—Several Scotch papers record an enormous increase in the business of the electricity supply works at Aberdeen, by saying that the increase in current supplied during the past seven months was "75,527 *volts*" more than for the corresponding period last year. The total revenue for current supplied during the past year has been £4,804, a decrease of over £900 compared with the preceding year. The expenditure was £2,081, against £2,596 for 1897-98.

Beverley.—The town clerk is to continue his inquiries *re* electric lighting in other towns, and report to the next Council meeting.

Cardiff.—On a wet day last week there was a leakage of current from the mains in St. Mary Street. Several passers by are reported to have received shocks. The first to notice the occurrence was a little dog, who went up to an iron pillar in the usual way.

Carlisle.—The General Purposes Committee have had before them the tenders for the plant required for electric light extensions, and have appointed a sub-committee to confer with Prof. Kennedy *re* same.

Cheltenham.—A special Council meeting is to be held to resolve to apply for a provisional order for the extension of the electric light area at Charlton Kings, Leckhampton, Bishop's Cleeve, and other adjacent villages. A Local Government Board inquiry is to be held *re* the proposed loan of £16,600 for electric lighting.

Dolgelly.—A member of the District Council is calling attention to the desirability of having the town lighted by electricity.

Edinburgh.—A steam pipe at the Dewar Place electricity works burst on Tuesday last week. No one was injured.

Germany.—A company is in course of formation in Chemnitz to establish a large central power station to supply energy to an electric tramway between that town and Burgstadt, and for lighting purposes to a number of small towns in the district.

Glasgow.—The Watching and Lighting Committee last week considered the minutes of the sub-committee on electric lighting of streets, from which it appeared that it had been remitted to the inspector of lighting and the electrical engineer to report how to modify the cost of electric lighting. Mr. Chamen, the electrical engineer, had reported that he did not think any increase in the distance between the lamps could be safely recommended. The average distance apart, as proposed by the inspector of lighting, is 50 yards, and that is the practice usually adopted in all other important cities. For outlying districts it might be possible to increase the distance to 60, or even 70 yards; but if arc lamps were spaced thus far apart, the space between them would appear to the eye far darker than it really was. The electrical engineer also pointed out that in Princes Street, Edinburgh, the lamps are only an average distance of 45 yards apart, and are about half as powerful again as those in Glasgow. The conclusion he came to, therefore, was that he could not take the responsibility of advising that the arrangement and number of lamps be in any way reduced; and he further pointed out that the price of £14 per annum per lamp for lamps lighted the

Digitized by Google

whole night through was the lowest in the kingdom, with the exception, perhaps, of Edinburgh, where, however, the price of £14 per lamp per annum is an all round price for lamps lighted—some all night, and some half the night. On the other hand, the capital cost and maintenance of the arc lamp pillars, lamps, and all accessories, is borne by the Electricity Department. The inspector of lighting, in his report, detailed the routes to be dealt with. The sub-committee recommended that the streets described in the report be lighted by electricity. The Watching and Lighting Committee approved the minutes.

Consumers have been circularised by the Electricity Department *re* systems of charging for current, and asking under which system they prefer to be assessed, viz:—

1. On the Maximum Demand System —For any quantity of current taken up to, but not exceeding the maximum demand for 365 hours in the 12 months, from June 1st, 1899 (being an average of one hour per day), 6d. per Board of Trade unit; all current consumed over the above-stated quantity 1½d. per Board of Trade unit. With the alternative of paying on—

2. The Fixed Charged System.—A fixed charge of 4s. per annum for each 8 c.p. (32-watt) lamp, or its equivalent, fixed in consumer's premises (or £6 5s. per kw.), this charge being spread uniformly over the 12 months from June 1st, 1899, and an additional charge for all current used as recorded on the meter of 1½d. per Board of Trade unit.

Consumers who take a supply of current for the equivalent of five hours or more per day for 365 days per annum, to be charged throughout at the rate of 1½d. per unit.

It is expected that the scheme for electrically lighting the Glasgow Harbour will be completed next month. Most of the small cranes in the Prince's and Kingston Docks will be worked by electric power.

Grays.—Mr. Preece has advised the District Council that there will be no difficulty in supplying Little Thurrock with electric light if that district obtains an order. The Council is making inquiries.

Halifax.—Tenders for masonry, joiners', plumbers', and other work in connection with the extension of the electricity works have been accepted.

Heckmondwike.—The Council has considered plans and estimates, prepared by Mr. Hawtayne, for electricity works, and the Electric Lighting Committee's recommendation to apply for a £14,000 loan to carry out the scheme, has been adopted.

Hereford.—The laying of electric light cables is nearly finished. It is thought that the works may be ready for opening at the end of October.

Hertford.—The *London Gazette* contains the usual formal notice of the intention of the Council to transfer its provisional order to the North Metropolitan Electrical Power Distribution Company, Limited.

Islington.—The Vestry is now commencing supply of current in various thoroughfares in Highbury Park at 200 volts.

Lambeth.—Work is progressing at a rapid rate at the electricity works with a view to being ready for the coming winter.

Leeds.—Since the electric lighting works of the Yorkshire House-to-House Electricity Company were taken over by the Leeds Corporation, towards the end of last year, the plant has been gradually extended to meet the growing demands. The Lighting Committee is not only adding to the machinery at present in use at the works in Whitehall Road, but is also taking steps to have extensions of a more comprehensive character carried out. Four new Lancashire boilers are nearly ready for use—these being of the type previously used. The management are also putting in, as an experiment, a boiler of the Babcock & Wilcox water-tube type. A 1,000-H.P. combined dynamo and engine is also being ordered, and two others of the same size are being constructed, one of which is to be at work before the winter. These are improvements that are to be carried out on the existing premises. With the demolition of the Britannia Mills, which has just begun during the last day or two, says the *Yorkshire Daily Post*, the Corporation will have at their disposal a valuable area for extension purposes. The Britannia Mills, which adjoin the present works and have a long frontage to Whitehall Road, cover an area of an acre and a half, or half an acre more than that on which the electric works now stand, and the space will be used to better advantage, inasmuch as the engines being of greater capacity than those on the other side, space will be economised. The cost of the old mills was included in the £217,000 purchase money that the Corporation paid to the Yorkshire House-to-House Company. For the erection of the new building and for its equipment, it is proposed to raise £150,000, and application for permission to borrow the money has been made. The engineer of the works (Mr. H. Dickinson) is just returning from the United States, where he has been making inquiries as to the different systems of generation and distribution of electric light, and Messrs. Hopkinson and Talbot are also to report as to the best plan to be followed in future work. The number of lights now connected with the mains is fully 50 per cent. more than it was at the same time last year. It should be added that the mains in the Hunslet district are just completed, and intending consumers in that part of the city may have their supply almost at once.

Liverpool.—The Electric Power and Lighting Committee recommended the Council at their meeting on Wednesday to accept a tender for the erection of an electric power station in Lister Drive for a sum of £49,783, and tender for the supply of three engines at a cost of £6,939 each, and three at £1,377 each, for the Lister Drive and Cobb's Quarry electric stations.

Llandilo.—The ratepayers are asking the Urban Council to take a house-to-house canvass *re* the electric lighting question.

An expert who recently gave an opinion *re* a scheme, calculated that the total cost of a 220-volt continuous current service would be about £2,900. Another £200 will have to be spent upon a provisional order. £500 may be saved if the Board of Trade will sanction the use of overhead mains. Within a couple of years 2,000 lamps will probably be used, giving an approximate revenue of £1,000 a year. The ratepayers' meeting sanctioned the Council to proceed with a complete system.

Norton.—The Council has informed Messrs. O'Gorman and Ockens-Hardy that it will be glad to consider any particulars they may be able to submit *re* electric light proposals for Norton.

Paisley.—The electricity works are all but completed. The total capacity of the plant is 18,000 8-c.p. lamps. Current was to be switched on on 5th inst. by the chairman of the Electric Lighting Committee.

Penarth.—It is stated that the Electrical Power Distribution Company will start immediately to construct electricity works near Lower Penarth.

Peterborough.—A request from a local company to be allowed to run an overhead wire from one depôt to another a short distance away for electric lighting has been refused by the Council.

Shoreditch.—The Lighting Committee, at a meeting of the Vestry on Tuesday, recommended the authority to purchase from Messrs. Lines for £14,500, the freehold of the wharf property facing Bath Place and Whiston Street for the purpose of a new generating station. Mr. H. E. Kershaw, in the absence of the chairman of the committee, moved the adoption of the recommendation. He stated that within 12 months the whole of the present plant and the new engines would be fully loaded, and that the Vestry would then be called upon to provide more light. The profit on the electric light undertaking during the past year exceeded that of the previous 12 months, and the authority would meet the reward of its municipal enterprise by undertaking the new scheme. There had been, the speaker said, a magnificent profit during the past year of between £3,000 and £4,000. Mr. Hall having seconded the motion, Major Wenborn proceeded to condemn the price proposed to be paid for the site as being excessive. Mr. Winkler said they were told years ago that the heat from the refuse would provide all the light required. Looking at the question now there was a great difference. There were five boilers in position, and the new scheme would involve a further expenditure of, perhaps, £30,000. He contended that the Vestry had been deceived in the matter; the destructor did not pay, and the speaker had always pointed out that it would not yield a profit. Other members having spoken, Mr. Kershaw, in reply to the discussion, said that he agreed that the price to be paid was high. *He would take that opportunity of withdrawing the statement which he made at the opening of the station—that the destructor would generate all the steam required;* but it was not possible at that time to foresee that the undertaking would grow to such a large extent. It was not true that the Vestry had been deceived as was suggested. If the destructor was allowed a fair value for the steam supplied and for the destruction of the refuse, a profit was shown on that department. On being put, the recommendation of the committee was adopted without any dissentient. It was decided to enter into a revised contract with the Brockie-Pell Arc Lamp Company, owing to the discontinuance of incandescent lamps on the street arc lamp standards, and by means of which a saving of £3 11s. per standard will be effected.

The Vestry on Tuesday approved regulations for the supply of electric current to tenements on the Moira Place and Plumber's Place areas, where workmen's dwellings have been erected by the Vestry under the Housing of the Working Classes Act. Among the regulations are the following:—

The main switches for regulating the supply will be under the control of the superintendent. The current to the rooms will be turned on each day at dusk and turned off at midnight. From October 1st to March 31st, the current will also be turned on at 5 a.m., and turned off at daylight. Tenants will be charged for the supply of electricity by an increase of the rent to the extent of 8d. per week for a two-room set, and 10d. per week for a three-room set, and such increased rent with any sums due for breakages, damages, or the like under these regulations will be recoverable as, and form part of the rent as and when the same becomes payable. One 16-c.p. lamp will be fitted in the living room, and one 8-c.p. lamp in each of the bedrooms. The Vestry will pay the cost of supplying and fixing wires and lamps and of renewing such lamps and wires except when broken or damaged by the tenant.

The Scottish Borders.—The Lighting Committee of St. Boswells have instructed Mr. Purves, Edinburgh, to make application this autumn for a provisional order for electric lighting. Mr. Purves has also suggested a scheme for Kelso, which he states to be admirably situated for the purpose, and the scheme includes the running of an electric tram from the town to the station. Hawick and Galashiels have also schemes under consideration.

Simla.—The electric lighting of Viceregal Lodge, Simla, will be thoroughly renovated next season at a cost of about 96,000 Rs. The present installation, which is 13 years old, is, according to a Delhi paper, obsolete and the plant now worn out.

Stoke-on-Trent.—The Board of Guardians has appointed Mr. G. R. Peers, of Manchester, to make an examination of the workhouse, and report to the Board upon the advisability and cost of installing electric light.

(*Continued on page* 404.)

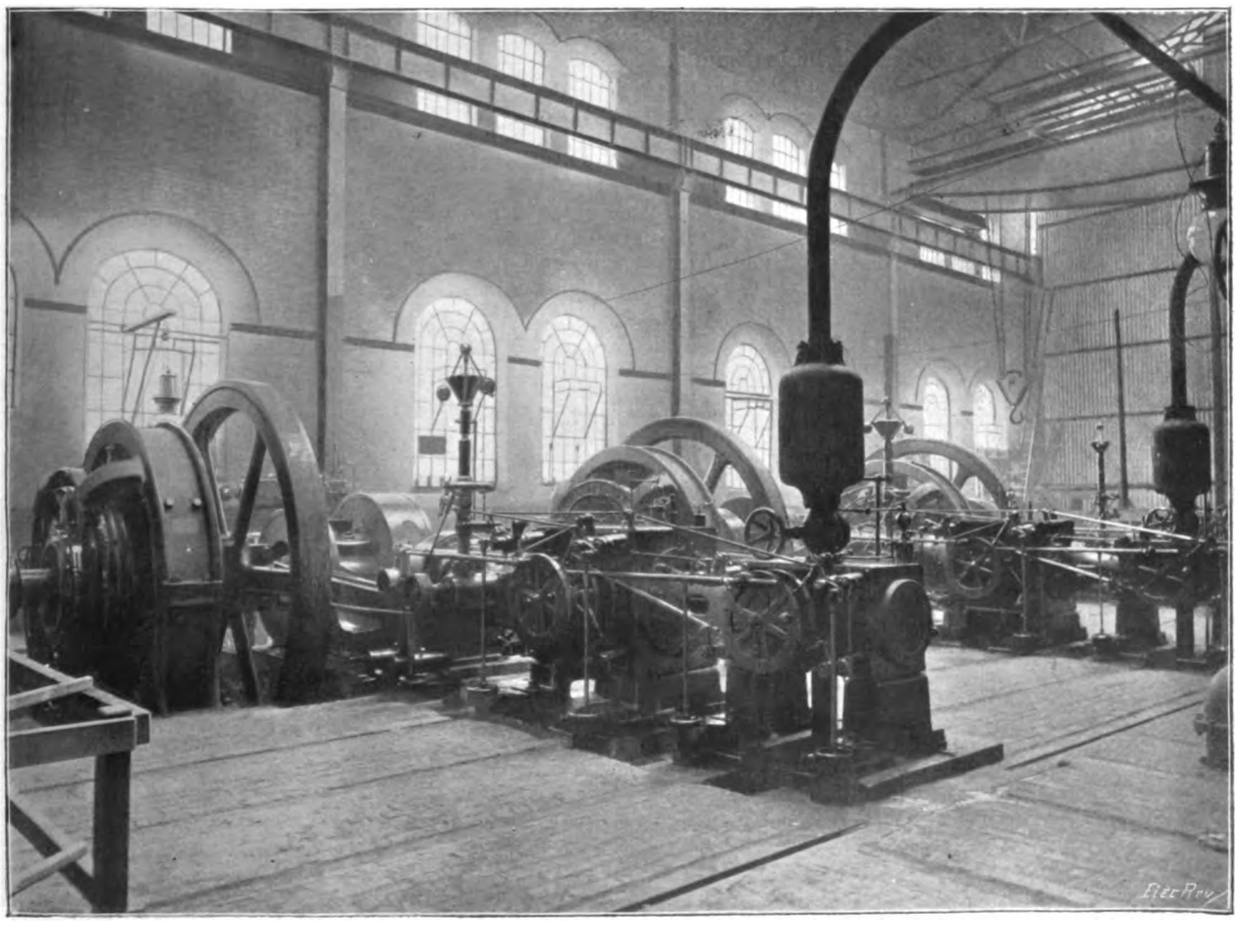
SHEFFIELD CORPORATION TRAMWAYS.

The city of Sheffield has a population of over one-third of a million, and covers an immense area, the outside measurements of the boundary being 4 miles by 12 miles; it is also very irregular, some parts of the city being a quarter of a mile higher above sea level than others. It would seem that here is a splendid field for mechanical traction, the gradients being too severe for animal haulage, except on certain routes. The old horse tramways first laid by the Corporation in 1872, and leased to a company, consisted of about 9¼ miles of double line; they remained at that figure for 24 years, when the lease expired. The Corporation then took over the working of the lines, and set to work with energy to popularise and improve the system. A deputation visited a number of British and Continental cities in September, 1896, to study the methods adopted there, with the inevitable result that electric traction on the overhead system was adopted, as being most suitable for the conditions prevailing at Sheffield. In 1897 powers were obtained for the construction of about 27 miles of double track, in addition to the 9 miles already existing, at an estimated cost of over £600,000, including electrical equipment. The work has been carried on rapidly, and the first 5 miles to be electrically equipped was inspected, on behalf of the Board of Trade, by Col. Marindin on August 25th for the Railway Department, and Mr. Trotter on August 29th for the Electrical Department. The first section of the lines, from Tinsley to Nether Edge, commenced regular running on Monday last; the Walkley section is also complete, but as

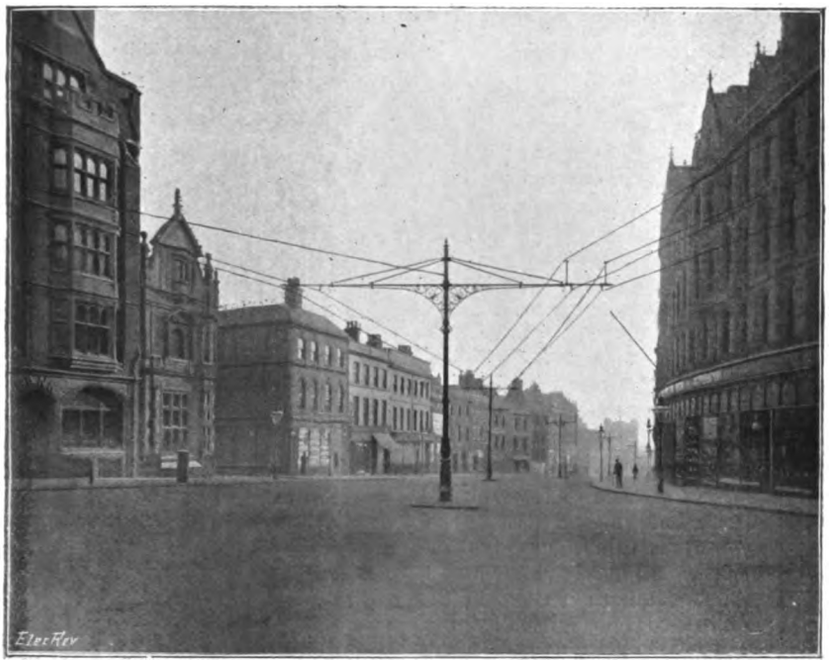
Street View.



Interior of Power House.

Digitized by Google

this abounds in excessively steep gradients, including some of 1 in 10, the drivers are to have a longer period of probation and training.



Street View.

The whole of the line work on the Nether Edge and Tinsley sections was done by the British Thomson-Houston Company. The equipment, including the generating plant, &c., was contracted for by the British Thomson-Houston Company, Limited. The extensions are being carried out by the Corporation staff.

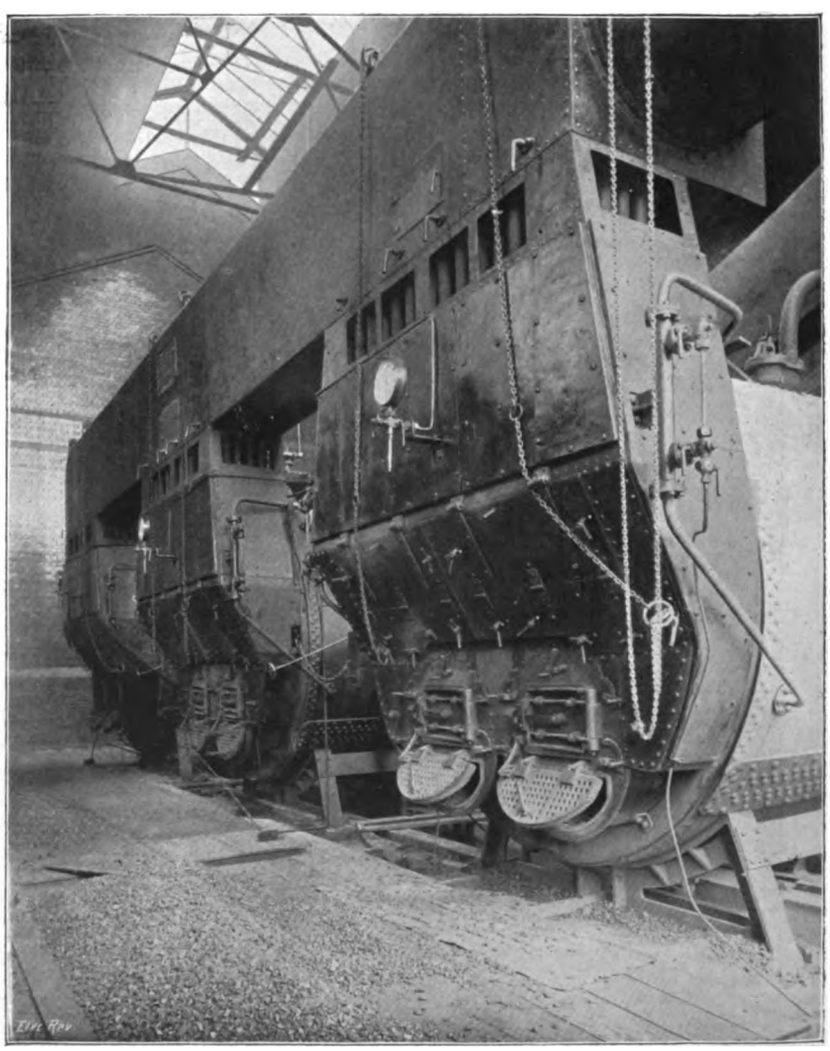
The power station consists at present of a building 110 feet wide, 90 feet long; the work of doubling the length is already in progress, and part of the additional machinery is almost ready for erection. The boiler house adjoins the engine room, and as will be seen from our illustrations, is very different from what we are accustomed to find in electricity works.

The boilers are of the marine "wet-back" multitubular type, and stand upon cast-iron chairs, without brick setting. They were built by Messrs. Vickers, Sons & Maxim at Barrow, and fitted with "Serve" tubes, "Ellis & Eaves" induced draught system and air heaters, by Messrs. John Brown & Co., Limited, Sheffield. Each boiler has two furnace tubes of the "Purves" ribbed type, somewhat resembling the Fox corrugated flues, but with ribs at intervals only; the combustion chamber, as the name "wet-back" implies, is entirely within the boiler, and the gases are returned to the fore end by "Serve" tubes of welded steel, which provide a large heating surface by means of inwardly projecting longitudinal ribs. The waste gases pass into a smoke box over the furnace doors, then through a large number of vertical tubes into the common flue above the boilers; from this they are drawn through trunks by fans and driven up the short steel chimney shaft, or at slack times they escape by natural draught. The air supply to the furnaces is admitted through traps seen in the front view of the flue, round the up-cast tubes from the smoke box; it then flows round the sides of the latter into the furnaces. The fans are two in number, direct driven by enclosed engines, which as well as the fans were made by Messrs. Thwaites Bros., Limited, Bradford.

The boilers work at a pressure of 160 lbs. per square inch, and are provided with thermometers and water gauges to show the state of the draught; they are fired by hand with small coal, and are each capable of evaporating 8,000 lbs. of water per hour. Four more boilers are on order, similar to those at present installed; they will be placed closer together—13 feet centres, instead of 17 feet 6 inches—and there will be one fan to three boilers, instead of 1 to 2, as at present. Mr. Fell also intends to instal conveyors, with automatic weighing machines, which will record the weight of coal received and the amount delivered to each stoker. A wide trench is provided under the ashpit doors, to accommodate an ash conveyor; the ashes will be dropped direct into the conveyor, and carried into a receptacle from which they can be removed at convenience.

Behind the boiler house there are coal stores, and a large tank, from which the circulation water is drawn. Water is admitted to the tank by means of a pipe from an adjoining "goit," or cut from the River Don, which flows past the site of the works, practically making it an island; the water is returned direct into the goit. The engineer's office is to be situated behind the boiler house, and over the former is a feed-water tank holding 11,000 gallons.

The steam pipes are of lap-welded steel with screwed



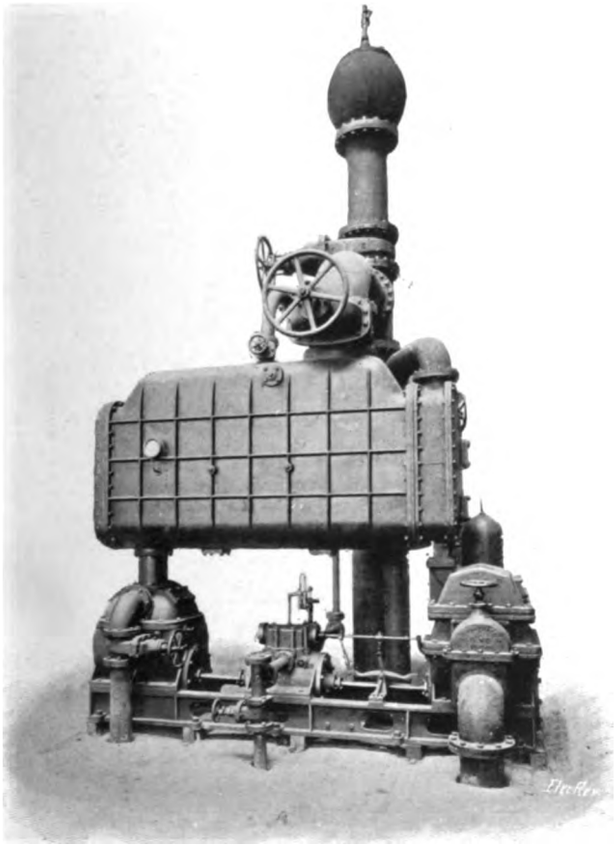
Marine Boilers.

Digitized by Google

flanges; no ring main is used, the boilers being connected to a single large header running along the boiler house wall; from the header a pipe is led to each engine, passing through a separator immediately above the high pressure cylinder. The steam junction valves in the boiler house, and the feed check-valves are of Hopkinson's make; all the piping was supplied by the Best Fox Manufacturing Company, of Philadelphia.

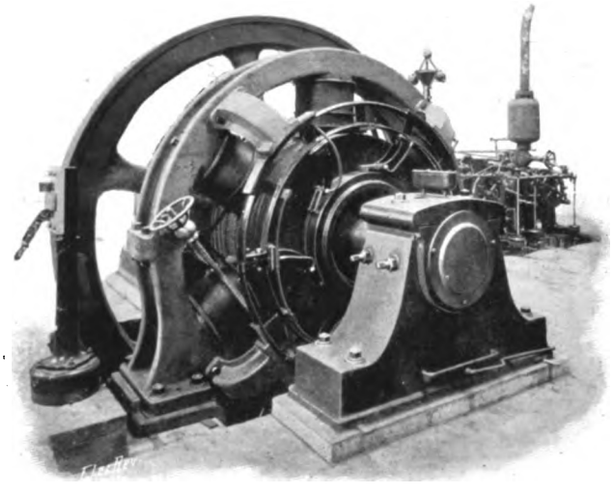
The condensing plant consists of a Wheeler "Admiralty" surface condenser having a tube surface of 1,900 square feet. The condenser is mounted directly upon Wheeler combined air and circulating pumps, as shown in our photograph, in which also the relief valve to atmosphere is seen above the condenser; the steam cylinder is 14 inches diameter, the air and water cylinders 16 inches diameter, and the stroke is 16 inches. The outfit is capable of caring for 19,000 lbs. of steam; it is fitted with Wheeler patent tubes, made of solid drawn brass, well tinned inside and outside, one end of the tube being drawn thick and having a thread chased on same, and screwed directly into the tube plate, thus making a mechanical and permanent joint, which will always be tight. The other end of the tube is secured by means of ferrule and corset lace packing which allows for the full expansion and contraction of the tubes.

Street View.



Condensing Plant.

Both the air and circulating pumps are operated by one steam cylinder. This steam cylinder is fitted with the maker's improved valve motion, which can be adjusted to run a full length of stroke under all conditions of speed, and there is no loss of motion, so that the economy in running this set is claimed to be very low. In the heater the same type of tube is used as in the condenser. The tubes are made of a large size, so that there is ample waterway and no choking of the feed-water on its way to the boiler. The area of the tubes through which the water passes is from five to six times the area of the feed pipe. Two more condensing sets similar to this are about to be erected. There is a horizontal Wheeler feed-water heater placed between the feed pumps and the boilers for utilising the heat of the exhaust steam from the auxiliary plant; the feed-water passes through tubes, the steam being outside. A pair of Edmiston feed-water filters are also provided, and are arranged so that the feed can be sent through either or both filters, or through a by-pass as desired. There are two "Manchester" vertical duplex pumps, made by Messrs. Pearn & Co., Limited, with cylinders 5½ inches diameter, rams 8½ inches, and stroke 5 inches. These, with the feed-heater and filters, are placed beneath the floor of the engine room.



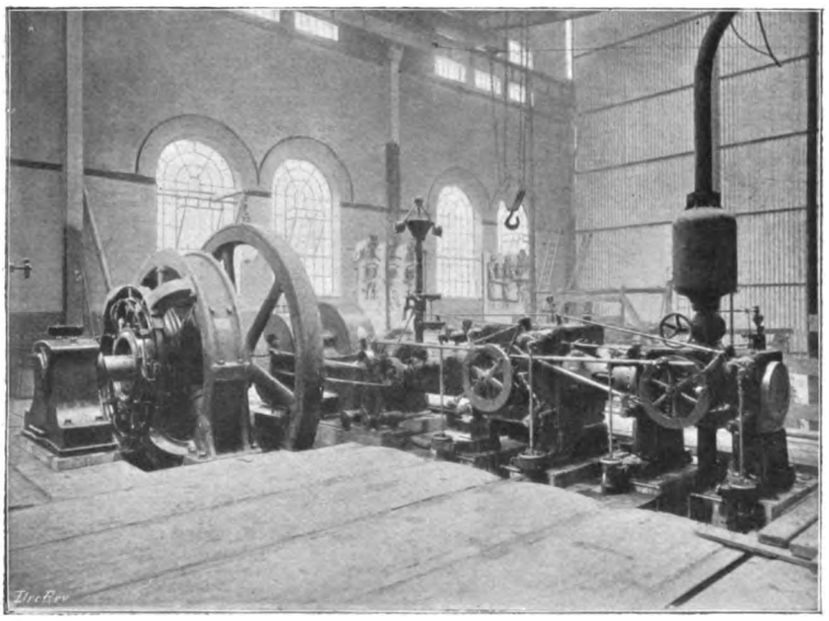
B.T.H. Railway Generator.

The engines are of the "Allis" horizontal tandem compound condensing type, three in number, with cylinders 12 and 22 inches × 30 inches stroke; their normal speed is 135 revolutions per minute, with a steam pressure of 150 lbs. per square inch. Reynolds-Corliss valve gear is used, with trip admission valves, and a gravity governor resembling the familiar Porter pattern. A jockey pulley running on the governor belt is connected by a loose link with the gear, so

Digitized by Google

that if the belt breaks the engine is stopped at once. The fly-wheel is 12 feet in diameter and weighs 6 tons.

The dynamos are standard B.T.H. six-pole railway generators, with drum armatures about 4 feet 6 inches in diameter, 1 foot 6 inches core width, and weighing 7 tons each.



Allis Engine and B.T.H. Generator.

The normal maximum output is 225 KW. at 500 volts. The field magnets are compound wound for constant pressure (within 2 per cent.) at all loads, with constant speed and fixed position of the brushes. The dynamo is coupled direct to the engine, with the fly-wheel between, and two bearings only are used. The brasses are supported in the middle, so as to be capable of a certain amount of self-adjustment, and the journals are oiled with drip lubricators.

The normal rated output of the engines is 350 I.H.P., but they are able to drive the dynamos at 25 per cent. overload, and the latter are designed to allow of this. An equalising switch is mounted on a pillar close to each generator, for parallel running.

An overhead travelling crane, to lift 20 tons, and made by Messrs. Booth & Bros., Limited, of Rodley, traverses the engine room. The latter is 100 feet long, 50 feet wide, and 40 feet high to the spring of the roof, while an extension 84 feet in length is already partly built. When completed, the room will be a very fine structure. Foundations are being laid for four additional generating sets, two of which are nearly ready for delivery. These will consist of B.T.H. dynamos of 500-KW. output coupled to vertical engines, cross compound, with Corliss valve gear, made by Messrs. Cole, Marchant and Morley, of Bradford. The armature and fly-wheel will be placed between the high and low pressure engines, and the whole will be mounted on a single compound cast-iron bed. The engines are designed for 800 I.H.P. at 90 revolutions per minute, and we are able to take 25 per cent. continuous overload in addition, if required; the fly-wheels, 18 feet in diameter, will weigh 23 tons each. A small 25-KW. coupled set, supplied by Messrs. T. Scott Anderson & Co., Sheffield, and consisting of a Silvertown dynamo and a Clench engine with fly-wheel governor, is used to run the glow lamps in the works.

The switchboard consists of three dynamo panels, two feeder panels, and two Board of Trade panels. The instruments, with the exception of Messrs. Elliott's recording ammeters and voltmeters, are all of the Weston illuminated dial type, and the switch-gear is of the usual B.T.H. type. Two of the Weston voltmeters are mounted on a swing bracket at one end of the board, so as to be visible to the attendant from any part of the switchboard. As may be seen in our general view, a large space has been left between the generator panels and the rest of the board, to provide for four generator panels for the extensions which are in progress.

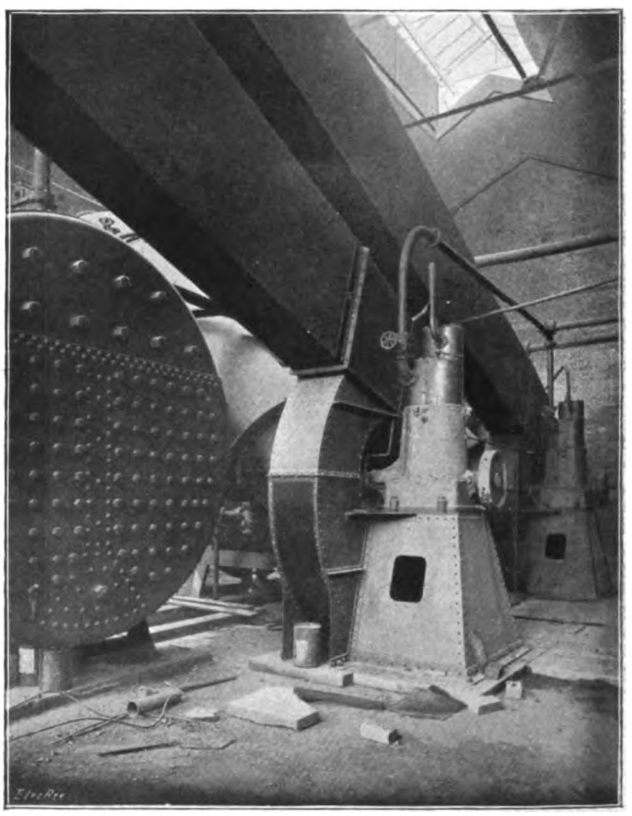
The board itself consists of white marble panels, supported in a cast-iron frame, and was supplied by the B.T.H. Company. The arc lamps in the works are run off the traction bus bars.

There are four feeders—two to Walkley, one to Nether Edge, and one to Tinsley—each to carry 300 amperes. The feeders are joined in pairs, and pass through two K type circuit breakers.

The cables are of the Callender type, insulated with jute saturated with fine bitumen, lead covered, taped and braided, with a specified insulation resistance of not less than 700 megohms per mile after 24 hours' immersion at 60° F. After laying and jointing, the cable must withstand a pressure of 1,000 volts for one hour. Messrs. Callender also supplied the cables connecting the trolley wire with the various feeder pillars, the return feeder cable, and the three-core test cable, the total length being over 13 miles.

The trolley wire feeders are 0·3 square inch in cross section; the return feeders from Tinsley and Nether Edge 0·6 square inch.

The overhead construction consists chiefly of bracket suspension, with centre and side poles; a good example of the former is seen in our photograph of South Street. There is a small amount of span wire work, which we show in a view of Fitzalan Square, as well as an interesting junction in the same neighbourhood. The line material is all of the B.T.H. standard type; the poles and brackets were made by Messrs. J. Spencer, of Wednesbury, and these, we think, show a distinct improvement in appearance over the ordinary designs.



Fans.

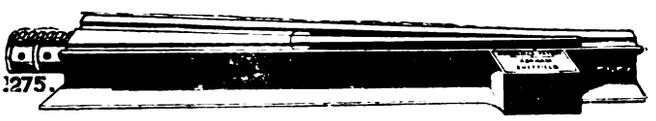
Some few of the poles were supplied by Messrs. MacFarlane, of Glasgow, direct to the Corporation.

The feeder pillars are of the B.T.H. type, and divide the trolley line into sections of a quarter of a mile each.

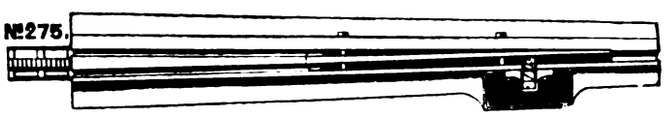
The track is laid on a 6-inch concrete foundation with rails weighing 108 lbs. per yard, made by Barrow Haematite Steel Company, Barrow-in-Furness, and bonded with Chicago

Digitized by Google

bonds. The special work at points and crossings was made in crucible cast-steel by Messrs. Askham Bros. & Wilson, Limited, of Sheffield. We show in one of our illustrations a view of an important junction, known as the Ecclesall Road junction. This was laid in about a fortnight, and leads to three important districts, Heeley, Nether Edge, and Ecclesall. All the points and crossings (36) were made in crucible cast-steel, to special angles required, by Messrs. Askham. In addition they have also supplied the drain rails, of which there are some hundreds, used upon the Sheffield tramways, also patent sole plates for junctions. The patent point and the drain



Movable Point.

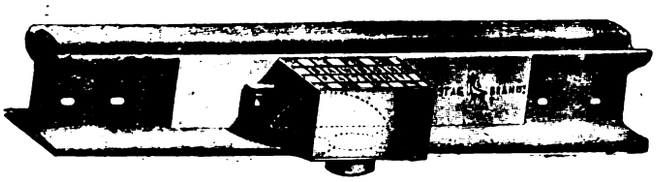


Fixed Points.

rail are shown in the small cuts. We understand that the patent points, of which some thousands have been made, have never yet failed. The loose part, or tongue, being made of forged steel, is not liable to break, and can be easily renewed. The drain rails are cast in crucible steel, and take the place of the ordinary rails for their length, about 5 feet. When connected with the sewers, the roads are drained by means of the slot cast in the groove of the rail, which allows the water to flow freely through. This arrangement is said to save their cost in six months by reduced repairs.

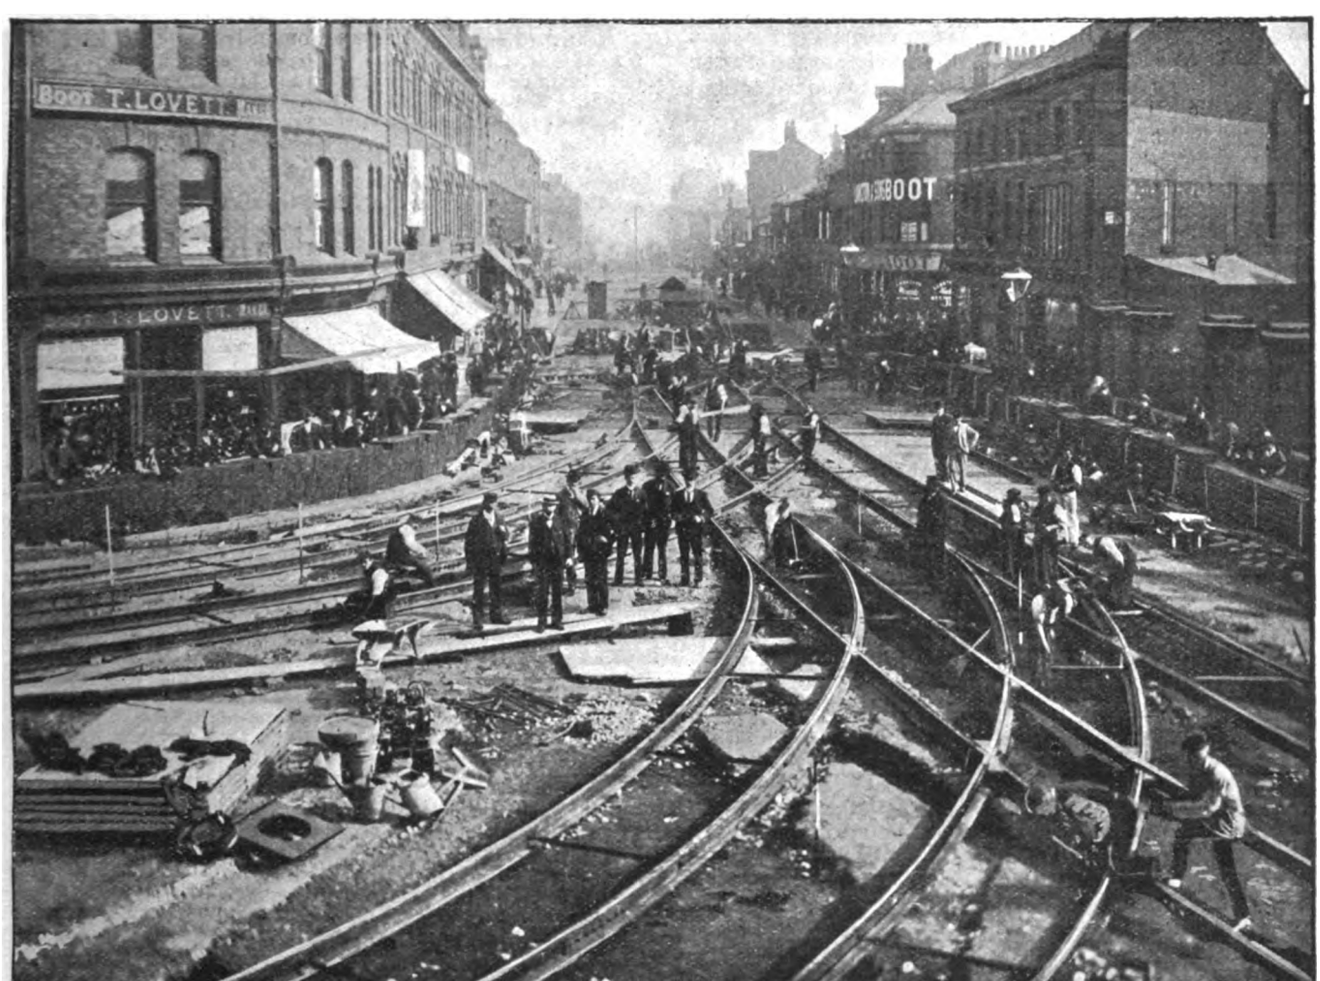
The total length of line equipped by the B.T.H. Company is 5¼ miles (double track). The rails were laid by Corporation workmen, and the overhead construction on the Walkley route was carried out in the same way. The fittings were supplied by the Electric Tramway Equipment Company, of Birmingham, and the trolley wire by Messrs. F. Smith & Co., of Halifax and Manchester. The amount of double track laid at present is about 12½ miles, most of which is ready for electrical working.

There are 52 electric cars already, and the number is to be increased to 80. Double-deck cars are employed on the Tinsley-Nether Edge route, weighing 8 tons each when empty; but the gradients on the Walkley station are so severe (some 1 in 10), that single-deck cars alone will run on that route, weighing 7 tons each, empty. Each car, in addition to the usual hand brake, has an electric brake, a slipper brake, and trailing Spencer's wedges or scotches. The electric brake consists of two discs, one keyed to the shaft with a feather, the other fixed to the frame of the truck, and fitted with a coil energised by the motors acting as generators. Hard steel wearing blocks are embedded in the discs, and show a marked improvement in the wear and in the smoothness of action of the brake.



Drain Rail.

The slipper brakes are to be used in descending steep hills, to get the car under control, while the magnetic and other brakes are used for regulating the speed. The slipper is



Special Work at Ecclesall Road Junction.

Digitized by Google

worked by a large hand wheel outside the ordinary brake handle. The object of the trailing wedge or scotch is to hold the car fast when it is stopped while going up an ascent; the wedge blocks or scotches are dropped behind the wheels by a special handle attached to the dash on the left-hand side of the platform. The handle operates the wedge blocks behind the leading wheels. The Mossberg and the Roller Bearings Companies' bearings have been supplied to some of the cars as an experiment. The trucks are of the Peckham extra long cantilever extension type, and were supplied to the B.T.H. Company by Messrs. R. W. Blackwell & Co. The car bodies are mostly of the top-seat type, built by Messrs. Milnes & Co., Birkenhead, and are capable of seating 22 passengers inside and 29 out. The length over all is 27 feet 6 inches, width over all 7 feet. The approximate weight of the bodies is 65 cwt. each (without trucks or passengers). The single-deckers carry 28 passengers each. All the cars are fitted with G.E.-52 traction motors, of which we gave an illustration last week; the controllers are of the B.T.H. manufacture, type B 13, and there is a magnetic circuit-breaker on each car. The side trolley post is just the same as at Bristol, and is very neat. Each car carries 12 lamps, of which 10 only are alight at one time; these give an excellent illumination, amply sufficient for reading.

Two sample smoking cars are on order, upon which Mr. Fell has spent a considerable amount of time and skill. Each has a small body in the middle, seating 16 persons, and a vestibule at each end seating six persons; but in one case the vestibule is provided with open lattice sides, in the other it is fitted with sliding windows. The driver's platform is completely shut off from the vestibule by a glazed partition.

Thirty cars and trucks have recently been ordered from the Preston Railway and Tramway Carriage Works, Limited, 15 of which will have Brill trucks, and the remainder Peckham trucks. These will be fitted by the British Thomson-Houston Company, Limited, with equipments similar to those described above. The latter company has also on order 25 other equipments, 13 double-deck cars and trucks, two eight-pole 500-KW. generators, two generator panels, and one feeder panel, in addition to the original contract.

We have to acknowledge our indebtedness to Mr. Fell, the city tramways electrical engineer; to Mr. Moller, the resident engineer of the B.T.H. Company, and to other engineers engaged upon the work, for their assistance in drawing up this description and for their courtesy to our representatives on the occasion of their visit; also to the British Thomson-Houston Company, Limited, which has furnished us with numerous details of the plant.

ELECTRIC LIGHTING NOTES.

(*Continued from page* 398.)

Stowmarket.—The Council will not allow the Suffolk Electricity Company to lay wires under a certain roadway for the purpose of supplying electricity to the East Stow Rural District Council.

Todmorden.—The Council has decided to call in an expert to report on the question of erecting works for the generation of electricity for the purposes of lighting, electric traction, motive power, and as to suitable area and the relative advantages of steam and water power.

Turkey.—We read that Sir E. Ashmead-Bartlett, M.P., gave a grand banquet at Constantinople last Saturday, to celebrate the granting of the first electrical concessions ever obtained in Turkey.

Valparaiso.—The *Review of the River Plate* says that a syndicate, called the Electrical Corporation, Limited, has been formed for the purpose of acquiring the concessions granted by the Municipality of Valparaiso to Mr. Josiah Harding, M.I.C.E. The syndicate is backed by some of the most powerful capitalists in London, who are prepared to provide the whole of the capital required for the construction. Mr. Harding recently returned to Valparaiso from Liverpool, accompanied by Mr. Maclaren, the engineer to the corporation, who will come back to England after the above-named preliminaries are arranged, and Mr. Harding will then remain as the representative of the company. Although steam will at first be used for generating the electricity, it is expected that water-power from the River Aconcagua will ultimately be transmitted electrically for the purpose of supplying the necessary current, not only for the tramways, but also for lighting and power throughout the city. The capital for purchasing and transforming the existing horse tramways will be also ready, so that a complete system may be installed as soon as possible.

Wakefield.—Messrs. Laing, Wharton & Down are pushing on with the electric lighting, heating, and power installation at the Wakefield Asylum. The engine house contains four sets of steam dynamos, two driven by 100 H.P., and two by 120 H.P. Willans engines. Electric radiators are provided. The number of lamps is 2,800, of which about 56 are arcs. The work has been in hand for about nine months, and is now completed. Mr. H. Kay has supervised the carrying out of the work.

Walker.—A deputation from the Council has visited Oldham and Rochdale for inspecting the electricity works. Negotiations has been opened with the Newcastle Corporation for the purchase of a site for electric works.

Winchcombe.—The Rural District Council has granted formal assent to the Corporation of Cheltenham to establish certain electric works in the parishes of Bishop's Cleeve, Southam, and Woodmancote.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Aberdeen.—The laying of rails and preparation of track for the electric tramways is proceeding with great expedition in the hands of Messrs. Macartney & M'Elroy, of London and New York.

Bedford.—The Electric Light Committee recommends the laying of a light railway between Bedford and Kempston.

Blackpool.—Several drivers of cars on the Blackpool and Fleetwood Electric Tramway have been fined sums varying from 10s. to 20s. for furious driving.

Bradford.—The Tramways Committee has let the contract for the rails and granite setts which will be required in the construction of three new electric lines: the White Abbey, the Thornbury and Stanningley, and the Lister Hills. The contract of the Demerbe Company for the whole of the rails was accepted, and the order for the setts was divided among several firms. Five or six years ago, as an experiment for the benefit of the Corporation, the Demerbe Company laid a short length of their rails on the Leeds road section of the Bradford tramways from Chapel Street to Harris Street, a portion of the line upon which the traffic is particularly heavy. The result has been highly satisfactory, and when the Bolton road electric tramway was constructed the rails were used for a length of 1,000 yards, from Bolton Church to the city boundary. They were also used by the Eccleshill District Council for another length of 1,000 yards in their district. That they have answered the purpose is shown by the committee's decision to use them solely in the construction of the three new lines. It is stated that the cost of the construction with the Demerbe rail is about £320 per mile less than with the old girder rail.

Darlington.—At Monday's meeting of the District Council a communication from the Light Railway Commissioners was read, stating that the Commissioners had decided to submit to the Board of Trade an order authorising the Darlington light railways. They recommend that the electric energy should be supplied by the Corporation of Darlington, and it was hoped that the promoters, before the scheme was finally sanctioned by the Board of Trade, would have made this arrangement.

Darwen.—At the last meeting of the Town Council, a statement was made upon the agreement which it was proposed to enter into with the Blackburn Corporation for working the recently acquired tramway between the two towns. It was proposed that instead of Blackburn paying a definite sum to Darwen and taking the whole of the receipts, the two Corporations should take the receipts in their own districts. The cost would be divided according to mileage. It was expected that the work of converting the tramways to the electric traction system would take about 12 months.

Eccles.—The Corporation General Purposes Committee has considered the report of the town clerk as to the proposed construction of electrical tramways from Salford to Whitefield. Six out of the nine districts represented at the joint conference, voted for a syndicate carrying out the whole of the scheme and three against. The borough surveyor, Mr. A. C. Turley, has prepared a scheme for the reconstruction of the tramways for electrical purposes. The length is over two miles, and the estimated cost of the reconstruction of the track, together with the provision of 10 passenger cars and the necessary plant, is £32,500.

Electric Railway Construction in Germany.—The *Society of Arts Journal* says that of the most important German cities, Aix la Chapelle, Brunswick, Chemnitz, Dresden, Hamburg, Hanover, Leipzig, Munich, and Stetten have almost completely abandoned horse cars, and are supplied by electric roads. In the cities of Berlin, Breslau, Cassel, Cologne, Frankfort-on-the-Main, Düsseldorf, Barmen, Elberfeld, Königsberg (East Prussia), and other places, horse lines are being converted into electric roads, and most of these have suburban electric roads completed. According to the

Digitized by Google

United States Consul at Düsseldorf, a large number of electric lines are being constructed in the country districts about Aix la Chapelle, Bochum, Gelsenkirchen, Düsseldorf, Vohwinkel, Elberfeld, Barmen, Elbthal, Essen, Krais, Hoerde, Reisengebirge, Waldenburg (Silesia), Witten-Ruhr, and in the mining districts of the Saar (southern Rheinland), and in Upper Silesia. In 35 cities and districts, not mentioned in the above lists, electric roads were in the course of construction on September 1st last, in nine of which the roads were completed and put into operation before the close of the year, so that at the beginning of the year 1899 there were 77 cities and districts in the empire supplied with electric roads. In 35 of these places extensions were being made to the lines in operation on September 1st, 1898, some of which were completed before January 1st. From a return which has been prepared on the subject, it appears that there were on September 1st last 888 miles of electric roads as compared with 595 miles at the corresponding date in 1897. There were in September last 3,190 motor cars as compared with 2,255 in 1897. Adding the roads put in operation since January 1st, 1899, it is estimated that there are now 930 miles of electric roads, with a total of 1,300 miles of tracks in Germany. From the city of Düsseldorf there are now four suburban electric lines completed. From Düsseldorf to Crefeld about 12 miles, from Düsseldorf to Rattigen about 8 miles, from Düsseldorf to Benrath about 6 miles, and from Düsseldorf to Kaiserwerth about 5 miles.

Electrical Omnibuses.—Whilst London has been promised and been expecting during the past year or two the arrival of a street service of electric omnibuses, the centre of promise now appears to have been transferred to Berlin, according to a *Financial Times* correspondent. The General Omnibus Company of that city has informed the municipal authorities that, in accordance with previous arrangements, a line of electric omnibuses will be experimentally placed on the streets during the present month in connection with the International Exhibition of Motor Cars, and that at the close of the exhibition the number of electric street cars will be increased. Suitable provision has been made for the recharging of the accumulators with which the omnibuses will be equipped, and the company hopes that the experiments will afford a practical test of the commercial value and prospects of electric omnibuses for the purpose of dealing with the passenger traffic of a large city like Berlin.

On Sunday last electric omnibuses were placed on the Berlin streets for public hire, the fare for about one mile being 20 pfennige (about 2d.). The speed is nowhere to exceed eight miles an hour. They are to run for the present in connection with a motor car exhibition, but should they prove a success the police are prepared to permit their general use.

Greenock.—The Law and Finance Committee of the Police Board conferred with a deputation from the Greenock and Port Glasgow Tramways Company last week, with a view to doing away with the deadlock in the negotiations with regard to the future working of the tramways and the adoption of electric traction.

Italy.—Ingegneri Arno & Caramagna is the style of a new firm which has just been formed in Turin, with a capital of £4,000, to introduce a new conduit system of electric traction.

Leeds.—The work required to be done before a service of electric cars can be permanently run between Boar Lane and Headingly is still unfinished, says the *Leeds Mercury*. In the early part of the year the members of the Tramways Committee thought that the cars would be running by the end of June or the beginning of July. They are still devoting their energies to pushing forward the work at the generating station. Only the engine and dynamos need completion; everything else is practically ready. Great efforts are being made by members of the Council to have the service in operation by November 1st. There are now 41 electric cars in the city. For the ordinary service between Kirkstall and Roundhay 21 are used, though at busy periods 30 are employed. By the time electric cars are required for the Headingley route, probably there will be another dozen motor-cars to hand. The tramway shed at Chapeltown is now being adapted for the accommodation of electric cars.

Liverpool.—Since the joint report of the city engineer, the city electrical engineer, and the general manager was issued in regard to a scheme of electric tramways for the whole city, the Tramways Committee have carefully considered the schedule of proposed new lines, with the result that 19 have been deleted out of the 42 proposed. The remaining lines, together with one or two additions not included in the report, will, says the *Liverpool Mercury*, come before the City Council at a special meeting to be held on Wednesday, October 4th, when the Council will have to consider, and if thought expedient, approve of a memorial to the Board of Trade for a provisional order for the construction of the proposed lines.

At Wednesday's meeting of the City Council the Tramways Committee asked for authority to reconstruct the lines for electric traction from Old Haymarket, along Victoria Street and North John Street to Lord Street, at an estimated cost of £4,284 for permanent way and paving, and £729 for overhead electric equipment.

Luton.—Mr. A. T. Snell has reported to the Corporation *re* electric traction. Notes are given of the Brussels system. The cost of the overhead wire system is given at £7,000 per mile and the conduit £11,000.

Newcastle.—The 14 tenders submitted for the boilers for the new tramway power station has been referred to the chairman of the Tramways Committee and the town clerk to report upon. Mr. Laws, the city engineer, advises the use of single-deck cars to accommodate 20 to 25 persons. The committee has agreed to this, but double-deckers will be also obtained for the Gosforth and Byker sections and to meet additional traffic. The engineer will report as to the cost of erecting car sheds. Mr. Charles Hopkinson has reported on the subject of lighting the thoroughfares with electricity. Arc lamps placed 40 yards apart on alternate sides of the main streets, and 80 yards apart in the outskirts, are recommended. Each lamp will cost £30, and the interest and redemption would amount to £5 15s. per lamp per annum. The cost of current would bring the cost per lamp per annum to £16 13s. 9d. There are at present 23 electric lamps in use at £42 per lamp, and the Electric Supply Company has offered to charge £18 per lamp if 100 are erected.

Sheffield.—On Monday the electric tramways, which are described elsewhere in this issue, were publicly inaugurated, the mayor setting the first car in motion. The guests numbering about 200, afterwards rode over the route in the new cars, subsequently inspecting the power station and sheds.

Staffordshire.—A Birmingham paper says that the British Electric Traction Company are proceeding with the reconstruction of the Dudley and Wolverhampton tramways, and their conversion to a 3 feet 6 inches gauge, the object being to assimilate it with that of the Dudley and Stourbridge and Kinver lines. The work will be pushed on vigorously, and it is hoped by the middle of next summer electric cars will be running on the Dudley and Wolverhampton line.

Sunderland-South Shields.—It is stated that the British Electric Traction Company proposes to connect Sunderland and South Shields, also Hebburn and Jarrow, with electric tramways.

Surrey.—The Highways and Bridges Committee of the Surrey County Council have prepared a memorandum for the consideration of the local authorities of Surrey, in the course of which they say that the fact "that the London County Council proposed to introduce light railways into Surrey and that extensive schemes for the county have been brought forward by other parties, have led this County Council to move in the matter, and to endeavour to secure in the interests of the county that a carefully-devised scheme, designed to meet the convenience of the inhabitants generally, shall be prepared for consideration and discussion as early as practicable. The first portion of the scheme will naturally deal with the districts more immediately adjoining the county of London, but eventually the requirements of the whole county must be considered; hence this invitation is made to all local authorities to express their views and to make proposals if they desire to do so, and communicate them to the Highways and Bridges Committee of this Council by October 20th."

Worcester.—The Streets and Electricity Committees reported to the Council on Tuesday regarding the application of the tramway company for the Council's co-operation in extending and improving the tramways. The company also proposes to construct light railways from the Cross to Kempsey and Red Hill. A deputation from the company had explained their proposals, and on the advice of the engineer consulted by the Committee, Mr. Waller, the deputation were asked to submit a draft agreement showing the best terms they could offer with reference to the price to be paid for electric current to be obtained from the Corporation for existing tramways and extensions and proposed light railways, and other details. After consideration of the reply of the company, the Committee passed a resolution that they would not advise the Council to consent to the Worcester Tramway Company's application for power to construct light railways in the city, but recommended the Council to oppose that application, and to take over the existing tramways at such time as was thought best, and to reconstruct them and to construct such additional tramways in the city as might be considered necessary, and to work the whole of the tramways. The company expressed disappointment at the recommendations of the Committee, which aimed at the defeat of the company's scheme, without making any definite alternative proposals. The project of the company had been to at once introduce into the city an improved electric system of tramways, and to extend similar advantages to all the principal suburbs and adjacent villages, the application for powers to construct light railways to Red Hill and Kempsey being preliminary only to further extensions for opening out the whole of the environs of Worcester. If the project was opposed by the Council, they would have to consider the necessity of advising the company to withdraw from the scheme altogether, and probably the much-needed light railways to places like Kempsey, Ombersley, Powick and Hallow would be wholly frustrated. It was not for them to express an opinion upon the wisdom or probability of the municipality embarking upon a speculative expenditure, the merely preliminary portion of which their advisers estimated at £73,000, which was not likely to fall short of £100,000, and from which the same advisers estimated a return of only £2,884 a year.

TELEGRAPH AND TELEPHONE NOTES.

Cables in the Pacific.—We make the following extract from an able article on "The New Pacific," which appeared in a recent issue of the *Saturday Review*:—"If Great Britain does not remain mistress of the Pacific as of other seas, the fault will be that of her sons under the Southern Cross. Federated Australia should count for at least as much as Japan; Canadian interests will be second only to those of the United States; British interests in China

Digitized by Google

are predominant, and the measures taken to protect them costly. From Hong Kong to Sydney, from Sydney to Vancouver, from Vancouver to Hong Kong, British interests eclipse all others. In a very large measure the future depends on the development of the spirit of unity between Australia and Canada under the fostering ægis of the mother country. The British Pacific cable will be both sound business in itself and an excellent sign and symbol of British solidarity. The United States will not probably be far behind with a cable from San Francisco to Hawaii and the Philippines. Neither Australia nor Canada is blind to the opportunities latent in the waters which at once unite and separate them. Of that they have given ample proof in the last few years in the starting of steamship lines, in their readiness to bear their share in the cost of constructing the proposed cable, and in their attitude on the subject of imperial defence. Australian federation is as momentous a fact in Pacific history as was the triumph of Japan in the war with China. Both events mean that new powers have arrived prepared to dispute with all comers for their respective rights. Australia a nation, however, will enjoy dignities, and must face responsibilities unknown to the individual colonies."

Continental Telephony.—It is stated that in consequence of the increased telephone traffic between Berlin and various places in Denmark, a new line will shortly be opened. Telephonic connection is now being established between Berlin and Warnemünde, whence a telegraph cable runs to Gjedser.

Dover Telephones.—The town officials are to report on the question of municipal telephony.

Harrow Telephone Service.—It is stated that the National Telephone Company has threatened to disconnect the Harrow subscribers from its system, in consequence of certain disagreements between itself and the Middlesex County Council regarding wayleave rentals.

The Pacific Cable.—A correspondent of the *Financial News* writes:—"Unlooked-for delay has arisen over the steps to be taken to secure the laying of the proposed cable across the Pacific to Australia. The Imperial Government and the Canadian and Australasian Colonies have come to terms, and the Colonial Legislatures are passing the necessary resolutions authorising their Governments to contribute to the cost. New South Wales is the only one that has not, though it is understood there is no fear as far as finance goes. Meanwhile the Colonial representatives in London appear to have got at loggerheads. On the committee to be set up Australasia has been allotted three representatives, Canada taking two seats and the Home Government three. New Zealand wants one of the three Australasian seats definitely allocated to her, because of her separate contribution and her geographical position. All the other Colonies are willing, with the exception of New South Wales, who is standing out for no 'earmarking' of any representation. In consequence of this, the whole matter of the representation has been referred to the Colonial Governments, and a couple of months, which could have been usefully spent in going into preliminary questions relating to cost of construction and maintenance, have been wasted. In fact, nothing has been done; and unless the Colonial Governments come to an understanding much quicker than their London representatives seem able to do, the question will have to be hung up for an even more indefinite period; for the Agents-General leave at the end of this month for America, to attend, at Philadelphia, the International Commercial Conference. Great irritation and annoyance exist in colonial circles over this delay."

Telegraphic Rates to South and Central Africa.—The *London Gazette* for last Tuesday states that on and after the 1st inst. the following rates will be charged for each word in telegrams to the undermentioned countries and territories in South and Central Africa:—Cape Colony, Natal, Orange Free State, Transvaal and Zululand, 4s.; British Central Africa (Nyassaland), 4s. 5d.; Portuguese East Africa—Beira, Fontesvilla, Anconzi, Bandara, Candida, Chimara, Chinde, Chiromo, Iumbo, Macaze, Maquivalvilla, Masangona, Mbgurrumba, Mechure, Mhassenge, Mularara, Ntumbe, Pinda, Quaqua River, Quilimane, Singal, Tangalene, Tete and Vicente, 4s. 6d.; Swakopmund (German South-West Africa), 4s. 2d.; Northern Rhodesia, 4s. 5d.; and Southern Rhodesia, 4s. 6d.

Uganda Telegraphs.—In a note on the departure of Sir H. H. Johnston's expedition for Uganda last week, the *Times* says that direct communication between the Imperial Government and its representatives in Uganda is now a *fait accompli*. The telegraph line has in fact reached the shores of Victoria Nyanza. The wire is working admirably, and telegrams are now constantly being received at Downing Street from the acting Commissioner well within 24 hours of their despatch from Uganda.

CONTRACTS OPEN AND CLOSED.

OPEN.

Barking Town.—October 24th. The District Council wants tenders for boilers, pipe work, two 100-kw. steam dynamos, switchboard, motor and trailer cars, trucks and electrical equipment, overhead equipment, underground feeders, conduits, road work, &c., for the Barking and Beckton light railways. See "Official Notices" September 1st.

Barnsley.—September 16th. Tenders are wanted for electric light wiring and fittings at the Harvey Institute, Eldon Street, for about 700 lights. See "Official Notices" August 18th.

Belfast.—September 31st. The Electric Committee wants tenders for c.i. floor plates and w.i. rails for the electric light department. Specifications from the city electrical engineer on payment of one guinea, returnable as usual.

Bermondsey.—September 13th. The Vestry wants tenders for electric lighting work at the Town Hall. See "Official Notices" September 1st.

Blackburn.—September 20th. The Corporation wants tenders for 40 electric cars and two 256-kw. steam dynamos. See "Official Notices" this week.

Carlisle.—September 11th. The Corporation wants tenders for extension to steam, drain, and feed pipes, feed pump, and extension of economiser at the electricity works. See "Official Notices" August 18th.

Carlisle.—September 18th. The Corporation wants tenders for extension of switchboard for dynamos 5 and 6, and for traction work. See "Official Notices" September 1st.

Darwen.—September 25th. The Corporation wants tenders for a high speed vertical engine and dynamo (300 to 350 kw.); also switch work. See "Official Notices" to-day.

East Ham.—September 9th. The Urban District Council wants tenders for combined electric light and traction plant, engines, generators, overhead line equipment, cars, switchboard, arc lamps, &c., water-tube boilers, condensers, and other steam plant, electric light cable. Mr. W. C. Ullmann, The Limes, White Post Lane, East Ham, is the Council's electrical engineer. See "Official Notices" August 4th.

Germany.—September 20th. Tenders are being invited until September 20th by the Cotton Wool Exchange authorities in Bremen for a complete installation of electric lighting in the new Exchange. Tenders are to be sent to Das Banbureau für die Bremer Baumvoll börse la Dechanatstrasse, Bremen, whence particulars may be obtained.

Germany.—October 16th. Tenders are being invited by the municipal lighting and tramway authorities of Königsberg, Prussia, until October 16th, for the supply of six boilers required in connection with the extension of the electric power station, to supply steam to new engines aggregating 1,800 E.H.P. Tenders to be sent to Die Direction der Städt, Belenchtungswerke und der Electr. Strassenbahnen Kaiserstrasse 41, Königsberg, Prussia, whence particulars may be obtained for 1s.

Glasgow.—October 10th. In connection with the tramway scheme the Corporation wants tenders for switchboards, fuel economisers, two 50 and one 30-ton electric travellers, power station steel work, and cables. See "Official Notices" to-day.

Hackney.—September 12th. The Vestry wants tenders for four sets of direct current steam dynamos (either high or low speed). See "Official Notices" August 11th.

Heckmondwike.—September 20th. The District Council wants tenders for the supply of water-tube boilers, economiser, pipe work, steam dynamos and motor boosters, accumulators, switchboard work, travelling crane, mains, arc lamps and posts, and station lighting. See "Official Notices" August 25th.

Ilfracombe.—September 25th. The District Council wants tenders for boiler plant, engine plant, dynamos, condensers, switchboard, mains, lamp-posts, accumulators, meters, crane, buildings, &c. See "Official Notices" August 18th.

Digitized by Google

Luton.—September 22nd. The Council wants tenders for boilers, superheaters, engines, dynamos, switchboard, steam and other piping, batteries, street conduits, boxes, feeders, arc lamps and posts, and various other plant and machinery for the electric lighting installation. See "Official Notices" August 25th.

Middleton.—September 20th. The Corporation wants tenders for Lancashire boilers, superheaters, economisers, steam pumps, condensers, steam dynamos, balancer and boosters, switchboard, accumulators, cables, crane, &c., for electricity works. See "Official Notices" September 1st.

Oldham.—The Electric Light Committee invites tenders for rolled steel girders, concreting, and other works required in the foundations for "Kleins Tower Water Cooler" at the electric light station, Gas Street, Oldham.

Rotherham.—October 9th. The Corporation wants tenders for Lancashire boilers, engines, dynamos, piping, condenser, economiser, battery, switchboard and boosters, feeders, mains, road work, &c., for electric lighting. For particulars see "Official Notices" this week.

Runcorn.—September 27th. The Urban Council is inviting offers for the electric lighting of the district, to be sent to the chairman of the Highways Committee.

Russia.—The municipal authorities of Perm are at present inviting tenders for the concession for the establishment and exploitation of a central electric lighting station in the town.

St. Annes-on-the-Sea.—September 11th. The Council wants tenders for high speed engines, continuous current dynamos, and balancing booster, for electric lighting. See "Official Notices" August 18th.

Salford.—September 12th. The Tramways Committee is inviting tenders for 100 tramcars. See "Official Notices" September 1st.

South Wales.—September 28th. The proprietors of Margam Copper Works, Port Talbot, wants tenders for the electric lighting (arc and incandescent) of their works. See "Official Notices" this week.

Sunderland.—The Corporation wants tenders for four 270-KW. three-crank direct current steam dynamos, and two surface condensers and cooling tower. See "Official Notices" August 18th.

Sydney (N.S.W.).—November 3rd. The Municipal Council of Sydney is inviting tenders for the construction and erection of a refuse destructor for treating 60 tons of refuse per day (24 hours).

Warrington.—September 30th. The Committee of Visitors of the Winwick Asylum, near Warrington, invite tenders for Contract No. 1.—Generating plant, including three sets of condensing engines or turbines, with directly coupled dynamos, each of 100 KW. output at 220 volts, booster set, motors, surface condensers, cooling tower, steam and exhaust pipes, &c. Contract No. 2.—Switchboard. The drawings can be inspected and specifications obtained of J. P. Muspratt, Clerk to the Committee of Visitors, County Offices, Preston, on payment of £2 2s for each specification, returnable. A separate tender must be sent in for the work included in each specification. See "Official Notices" this week.

CLOSED.

Aberdeen.—The Council has accepted tenders for supplies in the electric lighting department as follows:—Electric meters, Messrs. S. Z. de Ferranti; service cables, British Insulated Wire Company; house fuse boxes, Alex. Spark (local).

Dundee.—The following are the contracts for the laying of the Lochee and Perth Road electric tramway lines:—Perth Road, other than rails and fixings, Messrs. J. & C. Hay, £9,652 1s. 6d.; Lochee Road, Mr. R Sheach, jun., £11,892 11s. 1d.; rails, points, and crossings for Lochee Road and Perth Road, Messrs. Dick, Kerr, and Co., Limited, £9,698 5s. 8d. For the electrical equipment of the two routes the tender has been given to Messrs. R. W. Blackwell and Co., London, whose price was £5,931 10s. 2d. The total for the whole work is thus £37,174 8s. 5d.

FORTHCOMING EVENTS.

Friday, September 8th, at 2 o'clock.—Meeting of the Brush Electrical Engineering Company at Cannon Street Hotel.

Wednesday, September 13th.—The meeting of the British Association for the Advancement of Science opens at Dover with the presidential address of Sir Michael Foster. The sectional proceedings continue until Wednesday, 20th inst. The papers already announced include the following:—"Recent Applications of Electro-Metallurgy to Mechanical Engineering," by Mr. Sherard Cowper-Coles; "Electrical Machinery on Board Ship," by Mr. A. Siemens; "Earth Currents from Electric Tramways," by Mr. J. Swinburne; "The Niclausse Boiler," by Mr. M. Robinson.

On Saturday, 16th inst., in Section A, there will be papers by Profs. J. J. Thomson and Oliver Lodge, with a special view to the visit of the French Association.

On Monday, September 18th, Prof. Fleming will lecture on "The Centenary of the Electric Current."

On Tuesday, September 19th, the Automobile Exhibition opens at the Athletic Ground, and continues until 21st. Also on the 19th inst. there will be a paper by Prof. Threlfall on his gravity metre, and a discussion on "Platinum Thermometry" will be introduced by Prof. Callendar and Drs. Chappuis and Harker. In Section F a paper is expected by Mr. R. Donald (editor of the *Municipal Journal*) on "Municipal Trading." On Friday, 15th inst., Mr. Parsons will read a paper on "Turbines for Fast Cross Channel Service," in Section G.

Monday, September 18th.—The National Electrical Congress opens at Como and continues until September 23rd.

Tuesday, September 19th, at 10.30 a.m. (also September 20th and 21st).—Tenth annual general meeting of the Institution of Mining Engineers at University College, Sheffield. Among the papers down for reading is one by Mr. S. F. Walker, on "Alternating Currents and their Possible Applications to Mining." Part I.

NOTES.

Examination Tests.—Moralists sometimes tell us that the sum of evil on earth is a constant quantity, and there are many happenings that give support to this contention. The adoption of the system of entrance by examination by the Institution of Civil Engineers appeared at one time to have added a distinct load to the sum of evil, but, after all, it was not to be. The counterbalance has come in the shape of a notice from the Lords of the Committee of Council on Education that they have under consideration the discontinuance of the examination test in assessing grants in the elementary stage of science and art, the discontinuance to date after the year 1900. If there be nothing else, surely this will mark the date as a real *fin de siècle*. To assess the efficiency of education by inspection has much to recommend it. Much depends on the inspector. Not too lightly to disturb the existing calm of grantees, there is reserved provision for examination of such as wish to be examined and certificated on payment of a certain fee. This reservation spells weakness. If the examination system be faulty, why not reform it altogether? Half-measures are useless.

Indian Water-Power Scheme.—An Indian paper publishes a despatch from Simla (August 16th), stating that the Government has sanctioned a deputation to Europe and America of Captain A. de Lotbeniere, R.E., deputy chief engineer, Mysore Public Works Department, for six months, in connection with the Mysore Government's scheme for utilising the power of the Cauvery Falls at Sivasamudram, for generating electricity with a view to supplying the power obtained to the Kolar gold fields.

A Spelter Combine.—The latest in combinations is a scheme for controlling the world's production of spelter. Although details of the scheme are not yet divulged, the *Standard* learns that a combination of spelter producers is forming, and an agreement has been already arrived at between the Silesian and Belgium firms interested. It now only remains for the negotiations with the American producers to be brought to a successful conclusion. Such negotiations are now proceeding.

The Glasgow Electrical Tramway Contract.—A telegram from Glasgow late last evening informs us the Council has decided that Messrs. Musgrave and the Allis Company shall each make two of the main engines, but that a new detailed specification is to be made for the auxiliary engines. This is, after all, probably the best course that could have been taken.

The Conductivity Method of Studying Moderately Dilute Solutions of Double Salts.—In the *Philosophical Magazine*, (V.), Vol. 45, pages 151—157, there is a paper by James G. MacGregor and E. H. Archibald on the calculation of the conductivity of aqueous solutions containing two with no common ion. According to the dissociation theory, the specific conductivity of a complex solution, volume v of which contains N_1, N_2, N_3, &c., gramme equivalents of the electrolytes 1, 2, 3, &c., respectively, is given by the expression—

$$\frac{1}{v}\left(\alpha_1 N_1 \mu \infty_1 + \alpha_2 N_2 \mu \infty_2 + \alpha_3 N_3 \mu \infty_3 + \&c.\right)$$

where the α's are the coefficients of ionisation of the electrolytes, and the $\mu\infty$'s their specific conductivities per gramme equivalent at infinite dilution. It is shown how equations sufficient for the determination of the α's and N's may be obtained for solutions containing two electrolytes with no common ion. A series of observations and calculations of the conductivity of solutions containing sodium and potassium chlorides and sulphates was made to test the results. The agreement between the observed and calculated values in the case of the more dilute solutions is satisfactory. There is a further paper by the same authors in the *Philosophical Magazine*, (V.), Vol. 46, pages 509—519. In the cases which they have investigated so far, the conductivity of solutions containing two electrolytes with a common ion is calculable by means of the dissociation theory up to a concentration of about 1 gramme equivalent per litre. The conductivity of solutions of the double sulphate of potassium and copper is similarly calculable only up to a concentration of about 0·1, and has at concentration 1 a considerably smaller value than that calculated on the assumption that no double molecules are present. The solutions of double salts have, at concentration unity, an appreciably smaller conductivity than the equivalent mixtures. The conductivities of mixtures, in molecular proportion, of solutions of zinc and copper sulphates, and of potassium and sodium sulphates, are calculable within the limits of observational error up to a concentration unity; and, therefore, the non-calculability in the case of the double salt solutions is probably not due to defective data. The differences between the observed and calculated values of the conductivity of the double salt solutions and of the equivalent mixtures, and between the observed values in these two sets of solutions, are such as would be accounted for by the presence of double molecules in both, and their presence in slightly greater number in the double salt solutions than in the equivalent mixtures.

The Institution of Electrical Engineers' Reunion in Switzerland.—Our representative writes:—"Up to the present the tour has been most successful and enjoyable, while at the same time it has embodied no small amount of real hard work. The only regrettable feature has been the unfortunate illness of Colonel Huber, who has done so much to facilitate the arrangements and render the reunion a success; Colonel Huber is seriously, but, we are happy to say, not dangerously ill, and is thereby debarred from taking part in the excursions and meetings. We trust that his recovery may be speedy and complete. The programme has been faithfully carried out as arranged, the members of the party having visited the magnificent power station at Rheinfelden, and the splendidly equipped works of Messrs. Brown, Boveri & Co., the Maschinenfabrik Oerlikon, and Messrs. Escher, Wyss & Co., besides various minor places of interest. Some disappointment having been occasioned by the visit to Messrs. Escher, Wyss and Co.'s works being alternative to that arranged for Messrs. Sulzer Bros., the energetic secretary of the Institution, Mr. W. G. McMillan, succeeded in arranging for an extra visit to the latter works to take place on the return journey from the Schaffhausen power station. On Tuesday a number of the members visited the Landes Museum in Zurich, which contains a most valuble collection of antiquities and objects of interest, while others, including several of the ladies of the party, inspected the Rüti Silk Weaving Factory. On Tuesday evening the members were entertained by the Schweizerischer Elektrotechnischer Verein and some Swiss firms to a banquet at the Tonhalle."

A New Calorimeter.—A new calorimeter for the testing of coal and other solid or liquid fuels is described in the *Street Railway Journal* as the invention of J. R. Chapman, of the North Chicago Street Railway Company. It consists of a water-sealed vessel, with an internal bomb, and suitable pipes for filling and emptying. At the top is an open glass tube, graduated, and 20 inches long. A funnel on a side stand pipe communicates to the bottom of the vessel. The bomb is closed by a plug screwed into its base, which is in one with the bore of the outer vessel. To use the apparatus this plug is removed, a given weight of fuel is placed in the bomb, and ignited by a platinum wire and battery. The outer vessel is filled with water until this stands at the zero mark in the glass tube. The whole is allowed to attain the temperature of the room; oxygen is passed into the bomb, and the fuel is ignited, when a given predetermined pressure has been attained, and temperature has become equable and uniform. Combustion is rapid, the bomb expands by heat, and forces water up the graduated tube, the maximum point being noted, and the differences of reading are observed between different fuels. There is no calculation necessary. Results are comparative and approximate alone, and obviously the rapidity of combustion will cause a variation of reading. Given a pure charcoal as a datum, it is probable that, as between one coal and another, there would not be serious difference in rapidity of combustion for a small sample, while the same may be said of different samples of liquid fuels. The use of more accurate instruments, such as Mahler's bomb, is debarred to the ordinary man, because of the necessity for special care and accuracy, and probably this new calorimeter, however far from absolute accuracy, and useless for an actual calorific evolution, will be sufficient for everyday comparisons. The difficulty with all fuel tests, other than those of liquid fuels, is, of course, the extreme difficulty in selecting a true sample.

Municipal Tramways of Neath.—The town of Neath has a tramway system, and has recently equipped it with gas motor cars on the system of the British Gas Traction Company, thus superseding the system of horse traction. In these days, when municipal authorities set every possible obstacle in the way of conveniences for ratepayers, whose servants they ought to be, it is satisfactory to find that the men who rule Neath have some ideas of progress. Gas traction may be a long way behind electric traction, but it is a long way better than the horse. There seems to be a good deal of unnecessary secrecy about this gas traction business, which we see referred to as the new system of the Gas Traction Company. We thought the system had been "perfected" long ago at Blackpool. Why this continued newness? It is nearly 20 years since a friend of ours considered a scheme for using gas engines on tramcars with vessels of compressed gas, but he went no further at the time as a patent was secured soon after by a Melbourne engineer on the same lines, and it did not seem advisable to pursue the matter to the length of a patent. How is it that to-day there can still be patents for gas traction? Does the British Gas Traction Company possess anything further than a gas engine worked by gas from a compressed charge—compressed only for convenience of carriage and arrangement on a car?

Magnetic "Lines of Force."—"E. R. P." writes to *Nature* as follows:—"In some text-books and by some lecturers (*e.g.* Prof. A. Gray, as reported in *Nature* of August 17th, p. 379), the lines of magnetic force are said to be the curves along which iron filings are marshalled when sifted over a piece of card laid over a horizontally placed magnet. Surely this is hardly correct. The true line of magnetic force must be represented, like those of all other radiant forces, by radiating straight lines drawn through the points of action of the resultants of all the forces residing in the individual molecules of a given magnet (such points, though varying in position with the position of a magnetic body in the field, being often referred to as fixed 'poles'). The symmetrical figures traced out by iron filings merely show, of course, the directions in which a line joining the poles of a very short magnet will lie in different parts of a magnetic field, under the influence of the true lines of force."

The Paris Electrical Congress of 1900. — With regard to the Electrical Congress of 1900, Mr. Howard J. Rogers, director of education and social economy of the United States Commission to the Paris Exposition, has issued the following memorandum, which we cull from the *Electrical World and Engineer*, of New York :—"The Universal Exposition of 1900 is sure to gather together in Paris a great number of the scientists and engineers of the whole world. This justifies the French electricians in their efforts to organise an International Electrical Congress, which has received the official patronage of the French Government. In previous conferences questions of units and nomenclature have been settled by international agreement, to the immense advantage of all concerned. During the last 20 years there have been unexpected discoveries, new applications of what seemed once to belong to pure science, and an extraordinary expansion of electrical industries. Practice has thus started up a great number of problems on which it will be interesting and profitable to have the views of technical authorities. The discussions of the Congress will, therefore, have especially an industrial and economical character. The work is, provisionally, divided as follows :—(1) Scientific methods and instruments of measurements ; (2) production of electric energy, transformers, transfer and distribution, electric lighting, traction ; (3) electro-chemistry, electro-metallurgy, accumulators, electric furnaces ; (4) telegraphy, telephones, and various applications ; (5) electro-physiology. The Congress will last one week, beginning Friday, August 18th. The subscription for membership is 20 francs.

Presentation.—On Friday evening last at the Alexandra Hotel, Dale Street, Liverpool, an interesting presentation of a silver tea and coffee service with an illuminated address, was made to Mr. P. H. Naftel, of the Liverpool Corporation Electric Supply Works on the occasion of his marriage. Mr. Alfred Clough (works manager) who occupied the chair in the unavoidable absence of Mr. A. B. Holmes, the city electrical engineer, referred in felicitous terms to the respect and esteem in which Mr. Naftel is held by the whole of the staff and employés, and to his 15 years connection with the Liverpool Electric Supply Works. Mr. B. H. Collins, in supporting the chairman's remarks, briefly epitomised the progress made as regards the supply of electrical energy in Liverpool since 1883, when 120 lamps only were connected to the mains whereas there were now 103,000 16-c.p. lamps supplied.

The Car Injured.—A River Plate contemporary recently had the following :—"In the Paseo de Julio the electric tram ran over an old lady and was badly injured." Doubtless the lady will pay heavy compensation with a light heart.

Personal.—We hear with regret that Mr. Sutherland, the electrical engineer at Worcester electricity works, has been compelled to tender his resignation owing to ill-health, and the Council has unanimously granted him leave of absence for 12 months. A *locum tenens* will be appointed at £250 per annum, and the balance, £100, will be paid to Mr. Sutherland to act as consulting engineer. The advertisement appears among our "Official Notices" to-day.

Mr. Arthur Wright has accepted the appointment of managing director of the River Plate Electric Light and Traction Company, Limited (78, Coleman Street, E.C.), and has, in consequence, arranged with the British Thomson-Houston Company, Limited, to terminate his engagement as their retained consulting engineer on electric lighting matters.

Appointments Vacant.—The vacant chair of Natural Philosophy at Glasgow University, which carries with it £1,000 a year and an official residence, is now being advertised. Applications have to be submitted by 15th inst.

The Sunderland Corporation wants a competent engineering assistant to act as clerk of works and inspector in connection with the electric tramway construction works. Salary £250. See "Official Notices" this week.

Experiments with Nickel Steel Tubes.—Some very instructive experiments have been made by Mr. Yarrow on tubes of nickel steel with a view to ascertain the unstability of the material for tubes in boilers. We need not give the results in great detail as given in Mr. Yarrow's paper before the Institution of Naval Architects, sufficient to say the alloy known as nickel steel contains 20 to 25 per cent. of nickel. The tests simulated the more severe action to which tubes are exposed in boilers. Comparison was made with tubes of mild steel. Exposed to a dilute solution of hydrochloric acid, the nickel steel had a waste of only one-sixteenth to one-seventeenth that of mild steel tubes. Exposed to fire under the same conditions, the nickel steel lost by oxidation less than one-third of what the mild steel tubes lost. Tubes were heated, and at the same time exposed internally to a slow current of steam, and under these conditions a nickel-steel tube lasted out two and one-third tubes of mild steel, indicating much less frequent need for re-tubing. The same experiment, but with a dull in place of a bright red, showed 2·8 times durability of nickel steel in one case and a double durability in another case. A mild steel tube repeatedly heated and cooled showed a *decrease* in length of $\frac{56}{64}$ inch, where a nickel-steel tube *lengthened* only $\frac{14}{64}$ in the same length of 42 inches. Nickel steel appears to expand by heat one-third more than mild steel, as shown by tests on tubes 22 inches long, 1 inch diameter, and No. 16 L.S.G. This should be taken as a warning not to use nickel tubes amongst others of mild steel, as an element of risk will be introduced by the differential expansion. The ductility of nickel steel is considered ample for ordinary purposes. It is also tougher to work than mild steel, and involves greater wear and tear of tools, &c. Nickel steel is costly, but perhaps not less than its durability warrants. Small percentages of nickel, as 5 per cent., give a greater durability than mild steel possesses, but not sufficient to be of practical value. The nickel must be present to an extent of 20 to 25 per cent.

Lord Kelvin.—Lord Kelvin, although retiring from the Chair of Natural Philosophy at Glasgow University after 53 years, hopes that the change will not imply loss of intercourse and association in scientific work.

Appointment.—Mr. E. T. Williams, of Manchester, has been appointed assistant electrical engineer at the King's Lynn Corporation Electricity Works.

NEW COMPANY REGISTERED.

Robert W. Blackwell & Co., Limited (63,446).—This company was registered on August 29th, with a capital of £200,000 in £1 shares, to carry on the business of electricians, suppliers of electricity, manufacturers of cables, wires, lines, accumulators, lamps, and electrical accessories, and apparatus of all kinds; railway and tramway proprietors, engineers, &c.; and to enter into an agreement with Robert W. Blackwell, Philip Dawson and Benjamin H. Howell, carrying on a business under the style of "Robert W. Blackwell and Co." The first subscribers (each with one share) are:—A. J. T. Barker, 9, Throgmorton Avenue, E.C., gentleman; P. Dawson, 39, Victoria Street, S.W., engineer; F. H. Barker, 9, Throgmorton Avenue, E.C.; C. Dickenson, 122, Cannon Street, E.C.; A. H. Barker, Warnford Court, E.C., gentleman; B. H. Howell, 27, Portman Square, W., engineer; R. Brown, 5A, Wisteria Road, Lewisham, S.E., engineer. The number of directors is not to be less than three nor more than five; the first are Robert W. Blackwell, Philip Dawson, Benjamin H. Howell, and Francis H. Barker; qualification, £1,000; remuneration, £200 each per annum.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Chili Telephone Company, Limited (29,252).—This company's annual return was filed on August 23rd, when 44,000 shares were taken up out of a capital of £250,000 in £5 shares. £5 per share has been paid; total, £220,000.

Digitized by Google

Langdon-Davies Electric Motor Company, Limited (55,830).—This company's annual return was filed on August 16th, when 8,500 preference and 44,007 ordinary shares were taken up out of a nominal capital of £70,000 in 20,000 preference and 50,000 ordinary shares of £1 each. £12,507 has been paid on 8,500 preference and 4,007 ordinary shares, and £40,000 is considered as paid on 40,000 ordinary.

Edmundson's Electricity Corporation, Limited (52,013).—This company's annual return was filed on August 16th, when 4,500 deferred and 26,100 ordinary shares were taken up out of a nominal capital of £200,000 in 4,500 deferred and 35,500 ordinary shares of £5 each; £5 has been called up on each of 17,400 ordinary shares, resulting in the receipt of £87,000; £66,000 is considered as paid on 8,700 ordinary and 4,500 deferred.

Edison & Swan United Electric Light Company, Limited (18,984).—This company's annual return was filed on August 18th, when 116,400 "A" and 23,564 "B" shares were taken up out of a capital of £1,000,000 in 150,000 "A" and 50,000 "B" shares of £5 each; 10s. has been called on each of 89,621 "A," resulting in the receipt of £44,630 10s.; £456,667 10s. is considered as paid on 139,964 shares (£3 on 10,000 "A," £2 10s. on 89,261 "A," and £5 on 17,139 "A" and 23,564 "B.")

CITY NOTES.

Stock Exchange Notices.—The Committee has appointed Thursday, September 14th, a special settling day in Edmundson's Electricity Corporation, £75,000 4½ per cent. first mortgage debenture stock, and Willans & Robinson, Limited, further issue of 10,000 ordinary shares of £5 each, £1 paid, Nos. 80,001 to 90,000, and 10,000 6 per cent. cumulative preference shares of £5 each, £1 paid, Nos. 60,001 to 70,000. The application to quote Imperial Tramways Company, Limited, 10,000 6 per cent. cumulative preference shares of £10 each, fully paid, Nos. 1 to 10,000; 20,000 ordinary shares of £10 each, fully paid, Nos. 1 to 20,000; and 200,000 4½ per cent. first mortgage debenture stock, has been refused.

Prospectus.—The prospectus of the Kalgoorlie Electric Power and Lighting Corporation, Limited, will be found in our advertisement pages. The capital is £250,000, of which £150,000 6 per cent. preference capital is offered for subscription until Wednesday next. This sum will be entirely employed as working capital. In the first instance plant of 4,000 H.P. capacity (continuous supply) is to be installed.

Davis & Timmins, Limited.—The directors announce a dividend on the preference shares for the period ended June 30th last at the rate of 6 per cent. per annum, payable on 15th inst.

Commercial Cable Company.—The board has declared a quarterly dividend of 1¾ per cent. on the capital stock, payable 2nd prox.

TRAFFIC RECEIPTS.

The Blackpool and Fleetwood Tramroad Company.—The receipts for the week ending September 2nd, 1899, were £1,471 7s. 2d.; receipts for week ending September 2nd, 1898, £978 15s. 3d.; aggregate for half-year to date, £13,462 5s. 5d.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending September 1st, 1899, were £3,498 1s. 8d.; corresponding period 1898, £3,181 3s. 1d.; increase, £316 18s. 7d.

The City and South London Railway Company.—The receipts for the week ending September 3rd, 1899, were £891; week ending September 4th, 1898, £916; decrease, £25. Total receipts for half-year, 1899, £9,532; total receipts corresponding period, 1898, £9,611, decrease, £79. Miles open, 8½.

The Dover Corporation Electric Tramways.—The receipts for the week ending September 2nd 1899, were £293 4s. 11d.; week ending September 3rd, 1898, £248 0s. 10d.; increase, £45 4s. 1d. Total receipts to date, 1899, £6,781 5s. 8d.; corresponding period, 1898, £5,505 10s. 7d.; increase, £1,275 15s. 1d. Miles of track open, 1899, 8; 1898, 8. Car miles run, 1899, 4,932; 1898, 3,771. Number of cars, 1899, 12; 1898, 10.

The Dublin United Tramways Company.—The receipts for the week ending Friday, September 1st, 1899, were as follows:—D. U. T. Co., horse cars, £1,831 12s. 6d.; ditto, electric cars, £1,746 11s. 5d.; D. S. D. Co., electric cars, £1,121 15s. 2d.; total, £4,699 19s. 1d.; corresponding week last year—D. U. T. Co., horse cars, £2,924 9s. 8d.; ditto, electric cars, £498 18s. 10d.; D. S. D. Co., electric cars, £1,124 15s. 8d.; total, £4,548 3s 9d.; increase, £151 15s. 4d. Aggregate to date, £42,723 8s. 8d.; aggregate to date last year, £41,184 11s. 2d.; increase to date, £1,588 17s. 6d. Worked:—The mileage open is 21 miles electrically, 28 miles by horses, as against 12 miles electrically, and 30 miles by horses, for the corresponding period last year.

The Halifax Corporation Tramways. — The receipts for two weeks ending September 2nd, 1899, were £1,531. Miles of track open, 10. Car miles run, 22,906. Number of cars, 21. The receipts for two weeks ending September 7th, 1898, were £590. Miles of track open, 8½. Car miles run, 7,570. Number of cars, 10. Increase, £941.

The Liverpool Overhead Railway Company.—The receipts for the week ending September 3rd, 1899, amounted to £1,994; corresponding week last year £1,617; increase, £377.

The South Staffordshire Tramways Company.—The receipts for week ending September 1st, 1899, were £747 17s. 3d.; aggregate receipts for 35 weeks, £23,119 3s. 3d.; week ending September 2nd, 1898, £629 1s. 9d.; aggregate receipts for 35 weeks, £21,918 7s. 3d.

STOCKS AND SHARES.

Wednesday Evening.

Politics is the dominating feature of the Stock Exchange for the time being, and even the most optimistic of House men have shaken their heads this week at the Transvaal developments. The public are showing very little disposition to buy anything at all, and, consequently, trade in the steady-going electrical market is reduced to a minimum. The dealers stand idle in the market place all the day long, and admit that they see small chance of a general revival until the South African *impasse* has been broken, one way or the other. The telegraph section is naturally affected by the same cause, and in traction descriptions there is hardly a change to record.

In the electrical supply market the most noticeable alteration is in a name, not a quotation. The House-to-House Electric has been turned into the Brompton and Kensington Electricity Supply Company, but the old shares retain their place for the time being in the official lists, and no change is marked in the price. Edmundson's shares are quoted ex rights, and we understand that the new issue was fully subscribed. The price, however, remains unaltered. Of the metropolitan companies, City of London alone are being dealt in to any extent, but in these the daily bargains booked now are far short of the number done a month ago. Nothing has yet been announced with regard to a new issue of capital by the Charing Cross Company—in fact, there is even some doubt expressed in the Stock Exchange as to whether the company will avail itself of the right to enter the City, at any rate, for some considerable period. It is quite certain that a heavy emission of fresh capital to-day would meet with a very poor response, owing to the general caution that prevails.

Beyond the quoting of a few bonds ex dividend, the telegraph market is almost unchanged. Eastern Ordinary has given way, as it naturally would do upon growing fears of a war with the Krugerian band, but Eastern Extensions hold their ground with remarkable pertinacity. It is a matter of opinion as to whether the actual outbreak of hostilities would not be an excellent thing for the two Eastern companies, and hardy investors are picking up cheap stock when it comes into the market. Operators in Anglo-American telegraph stocks are resting upon their oars—the phrase, perhaps, applies literally, having regard to the empty appearance of the market in the Stock Exchange. There is very little to "go for," as the House says, and prices change too slowly for the average speculator to be tempted into dealing.

Electrical railway securities are lifeless. Central London Preferred half-shares are now £5 paid, but there is no business doing in them. "I dealt in Central Londons yesterday," quoth one of the principal jobbers to-day, "and it was the first bargain I had done in them for a week." Waterloo and City has not regained the point it lost last week. The price of City and South London has hardly moved for the past month.

We believe we are correct in stating that important negotiations are on foot for the absorption of the Birmingham Omnibus Company by the British Electric Traction, but no details have reached us at present. The British Electric should be able to acquire the 'Bus Company cheaply, and the bargain would probably turn out well. No change has taken place in the price of the shares. Calcutta Tramways show a slight tendency to react after their rapid advance, but there is a small buyer in the market at 9. Considering that some little time may elapse before the company is likely to reap any practical benefit from the electrifying of its line, we should imagine that holders whose shares show them a profit might do worse than take it.

The Tramways Union Company announces that it has now sufficient money in hand to pay off the debentures in full, to return the capital to shareholders (*i.e.*, at the rate of £5 per share), and to add another 30s. per share thereto. Subsequent distributions will be made as its assets are realised, and the market is hoping that these will amount to at least a further £2 10s. per share. The price is now 8½—9. Barcelona Trams are 11—13, and Bordeaux keep steady at 12—14.

SOME FORMS OF MAGNETIC SEPARATORS, AND THEIR APPLICATION TO DIFFERENT ORES.*

By H. C. McNEILL, Assoc.R.S.M.

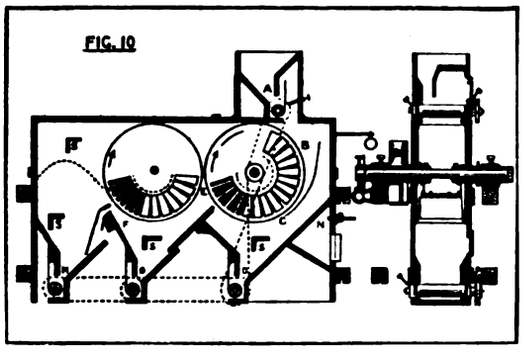
(*Concluded from page* 375.)

2. The Monarch Separator.

The Monarch separator may be regarded as a Wenström with the single drum duplicated; it is, however, of a rather more delicate construction, and is a modification of and improvement on the original Ball and Norton machine, a class which includes the most successful machines of the eccentrically placed internal electro-magnet and the revolving drum pattern. Fig. 10 shows a sectional elevation of this separator. It is necessary that the ore treated should be quite dry, and in both cases where the author was enabled to see the machine at work in Sweden the best results have been obtained upon material crushed to pass through a 1 millimetre screen.

The ore of the size mentioned, after drying, is fed in an even stream into the machine by means of the roller at A, the feed being capable of adjustment as shown. The mineral falls on the revolving drum, B, which moves over the fixed electro-magnets, all the material being compelled to pass close to the drum by means of the bent shield, B C. Having passed the point, C, the non-magnetic portion, or tailings, fall into compartment D, and are fed out at that point by a similar roller. At or near the point E the particles hop across to the next drum in consequence of a stronger current being employed in drum No. 2, and are possibly helped by an induced current of air caused by the superior velocity of this second drum, the relative speeds being as

FIG. 10



6:1. Those particles containing a little magnetite are whirled off drum No. 2 at about the point F, the centrifugal force being the stronger force of the two, and drop into the compartment, G, constituting "middles" or "middlings." The wholly magnetic particles are whirled off drum No. 2, at about the end of the electro-magnets, and are flung against the end of the machine, and are fed out at H.

The "middles" may be re-crushed and re-treated, if necessary. A combination of three such machines, where the middles from two of

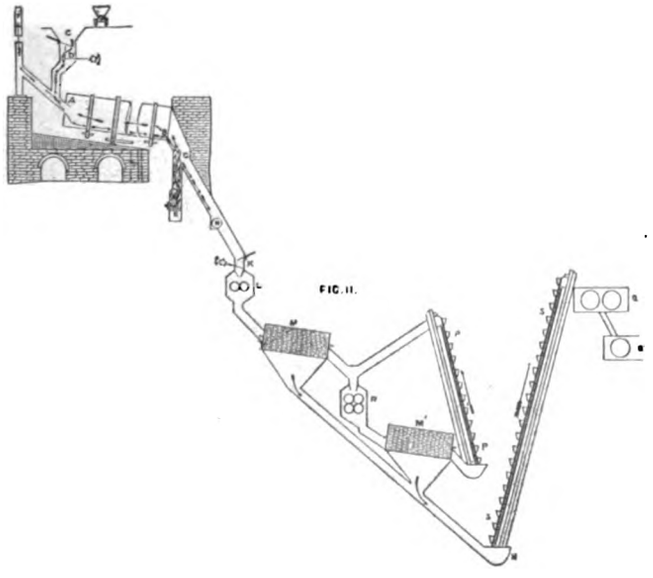


FIG. 11.

them are passed through a third, is said to be capable of treating 200 tons of uncleaned ore per day of 24 hours.

One of the later improvements on this separator is the introduction of drums made of German silver, which has been found to increase the efficiency of the machine.

This form of machine, when used after a careful preliminary treatment, such as drying, crushing, screening, &c., is applicable to two classes of ore:—

1. Those in which magnetite is more or less intimately associated with worthless material.

2. And those in which the magnetic portion is of secondary importance.

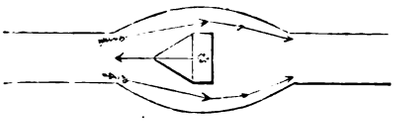
To both of which cases the machine is successfully applied.

The extensive plant seen by some of the members of this Institute whilst at Lulea, in the north of Sweden, last summer, may be taken as a case coming under the second of these conditions, and which may be briefly described as follows:—

The ore which is put through the mill assays from 0·01 per cent. to 3 per cent. phosphorus, and is correspondingly low in iron, the phosphorus occurring in the form of apatite. Only the ore richest in the latter mineral, and hand-selected on this account, is put through the mill.

It is first put through a Blake crusher and then through a single pair of Swenson rolls, the ore being thus reduced so as to pass through a ½-inch mesh screen. This product is then thoroughly dried by passing it through the revolving cylinder, A B, fig. 11. This cylinder is 48 feet in length and 4 feet 8 inches diameter; it is inclined 1 in 18, and rotates once every five seconds. The ore from the hopper, C, is by means of the feed-plates at D, passed in a constant stream into the cylinder, meeting the heated gases, &c., coming from the coal-fire at E. Having arrived at B, the ore, which is now quite dry and hot, falls down shoot G, being divided at that point into two streams (fig. 11A), in order to miss the uptake from the fireplace, E. At H is a revolving drum, and at K are placed an adjustable baffle-plate and a vibrating feed-tray, which not only acts as a safety catch to prevent

FIG. 11A.



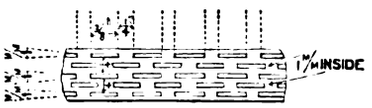


FIG. 11B.

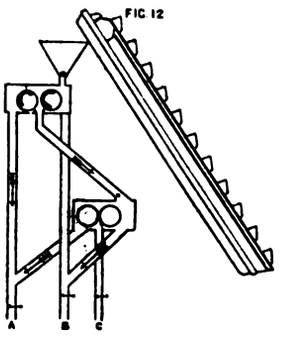
any object, such as a hammer-head, getting into the rolls, but also regulates the feed of ore, so that the rolls, L, have just sufficient ore to deal with, and do not get clogged up. After passing these rolls the ore enters the circular screen, M. This screen is of $\frac{1}{16}$th inch thick steel plate with oblong holes, the details of which are given in the sketch (fig. 11B). A certain proportion of the ore, about 20 per cent. of the whole, which finds its way, or is small enough to pass through M, drops right down to the bottom chamber, N, whilst the rest passes out of the screen, and is fed into the double rolls, B, and after that passes into a second and similar screen, M^1. The ore fine enough to pass through this second screen joins that which has already passed through the upper trommel, M, whilst that which is still too large is returned to the double rolls, B, by means of the elevator, P P, and is re-crushed. Assuming the chamber, N, to contain nothing but ore 1 millimetre diameter, this is then transferred to a Monarch separator, Q, by the elevator, S S, the "middlings" from which pass down, and are sent through a second separator, Q^1.

The plant is in duplicate, *i.e.*, fig. 11 represents just one-half of the mill, each half working independently of the other half, and there are, therefore, four separators at work, two to each half.

The arrangement made for joining the like products from two separators is shown in fig. 12, where the two concentrates join

FIG 12



together and are collected at A, and the tailings similarly at B, whilst the "middles" from the top machine are taken to the lower separator, and the "middles" from which again collected at C.

All the screens, rolls, separators, elevators, shoots, &c., are boxed in with wood, and the dust from them, by means of mains and exhaust fans, drawn to a separate house, allowed to settle, and removed when necessary for further treatment.

* Read before the Iron and Steel Institute at Manchester, August, 1899.

Digitized by Google

It might be of interest to note that the tailings, consisting of apatite, with a very small proportion of magnetite and some hæmatite, constitutes the most valuable product delivered from the separators.

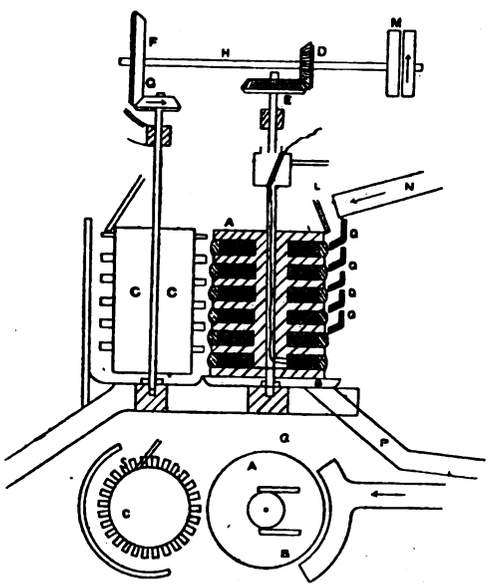
This then goes forward and receives further treatment for the separation of the small residual portions of iron compounds, and the finished phosphate of lime is finally converted into the soluble phosphate of soda by the Wiborgh process.

A similar plant to the one just described is also used, as already mentioned, where magnetite has to be separated from other and worthless minerals. In this case, the only point that it is necessary to draw attention to is that the ore itself, in the absence of any appreciable quantity of apatite, may be harder, and the initial crushing more difficult to accomplish. At Herräng a No. 5 Gates crusher is employed for this purpose.

3. The Dellvik-Gröndal Separator.

This machine is designed to treat those ores in which the magnetite exists in a state of intimate admixture with other and in general worthless minerals. At present it is at work, and is successfully treating low-grade magnetite ores. The preparation that the ore has to undergo before it is passed to this form of separator will be described when dealing with a plant now working at Bagga, in

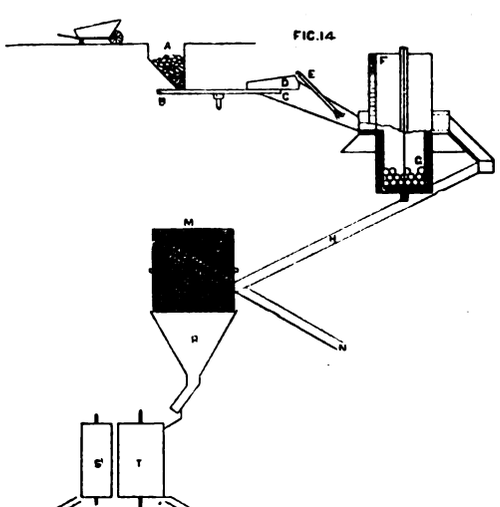
FIG. 13.



Sweden. For present purposes, the material may be described as a slime. Fig. 13 shows a sectional elevation and part plan of the machine. A B is of cast-iron, and consists of a series of rings. In the spaces between each of two is placed the copper wire conveying an electric current. This drum is rotated by means of the bevel gearing, D E, and the pulley-shaft, H.

C C is a solid drum of wood caused to revolve three times faster than A B by means of the gearing shown at F G, and is studded with

FIG. 14.



soft wrought-iron bolts or pegs, each ring of which revolves exactly opposite to the rings on A B. It will be noted, as indicated by the arrows, that A B revolves from right to left in front, and C C from left to right in front. The slime is carried to the machine by means of the launder, N, which terminates in the circular launders, Q Q Q Q, which enclose the drum, A B, for about one-third of its circumference, as seen in plan, and offer a larger area of the slime to be acted upon. Further water is supplied by the pipe, L. The magnetic particles thus brought under magnetic influence attach themselves to the rings on A B, and are carried round. Those particles which escape the first ring are caught lower down, and so on, each successive ring being more strongly magnetic than the one above. The unmagnetic portion of the ore, being unattracted, is washed down and into launder P, together with the excess water. As each peg of the drum C C is successively presented to the rings of the drum A B, magnetism is induced therein, and the magnetite hops over and forms in tufts on each peg, and is thus carried out of the magnetic field, where most drops away, and the rest is washed off by a strong jet of water from the pipe shown, this separated magnetite being run by the launder into settling pits, from which it is dug out.

The copper wires conveying the electric current are protected by carefully fitted brass rings and special jointing.

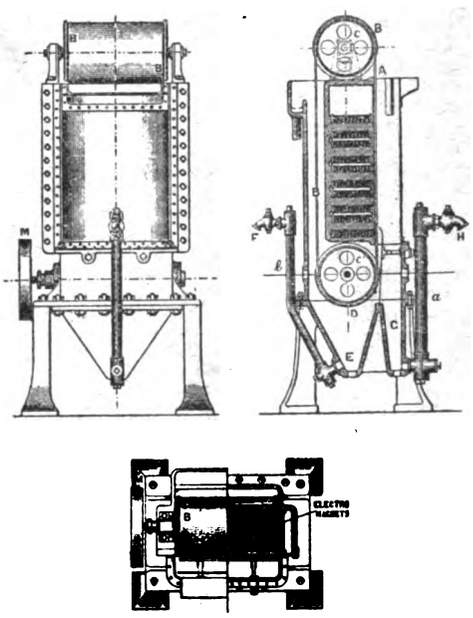


FIG. 15.

The necessary fine crushing before treatment in the separator is accomplished by means of a ball-mill. Fig. 14 is an attempt to show a small plant designed for the purpose of treating a low-grade ore, in which it is necessary that crushing should be carried to such a point that all the material shall pass through a 12-mesh screen. The first coarse crushing is done by means of a Blake machine, which reduces all the ore to about walnut size, after which it is passed through a ball-mill, a feature of which is an ingenious arrangement, by which a regular feed of ore is supplied to the mill. B C is a horizontal circular revolving plate, the height of which can be adjusted so that the distance between the bottom of the hopper, A, and the moving plate, B C, can be so regulated that just sufficient ore is allowed to drop through, and is carried round on the plate. D is a fixed guide-plate, under which the plate, B C, revolves, and the ore, in coming up against it, is slowly pushed off and into the shoot leading to the ball-mill F G. This is of cast-iron, lined internally with chilled plates, the latter removable, and is caused to rotate 40 times per minute upon hollow trunnions, through which ore is fed in on one side and out on the other, water being supplied by pipe E. Coarse slime is thus produced, and passes out with the excess water down an open launder H, and into a revolving screen M, of wire gauze, with 140 holes to the square inch. The stuff, already fine enough to pass through, drops into the shoot B, and is treated in the Dellvik-Gröndal separator S T, whilst that not sufficiently fine is carried up on the gauze inside, and drops from the top on to the enlarged end of a launder N, and is returned to the mill by a small pump.

Prof. G. Nordenström, in a paper read before this Institute at the Stockholm meeting last August, mentions the fact "that the Dellvik-Gröndal separator has been advantageously used at Pitkaranta, in Russian Finland, since 1894, for concentrating poor iron ores."

4. The Heberle Separator.

There are two distinct types of machine, each of which is shown in separate figures.

Fig. 15 is a type designed for the separation and concentration of low-grade magnetic ores only.

Fig. 16 is designed for the treatment of galena blende ores when occurring with magnetic oxide of iron; also the separation of roasted spathic iron and blende, &c., or in the treatment, which will be described below, of a complex ore consisting of galena blende, magnetic oxide, pyrrhotine, and quartz.

In fig. 15, the ore to be treated, after reduction to size of about 30-mesh, is fed in at A with water. B B is a continuous gutta-percha belt travelling round the pulleys C C, and over the fixed electro-magnets placed in the casing shown, the whole machine being enclosed in a wooden box, which is kept full of water to a height a little above the highest of the magnets. The magnetic portion of the ore attaches itself to the belt, and is carried down with it until,

Digitized by Google

arriving at D, and out of the field, falls away into E, and is withdrawn through F. The worthless portion falls into G, and is withdrawn through pipe H. The width of the belt may be from 1 foot 8 inches to 2 feet 6 inches, and a machine of the latter size is capable of treating 35 tons of crude ore per day. These separators may with

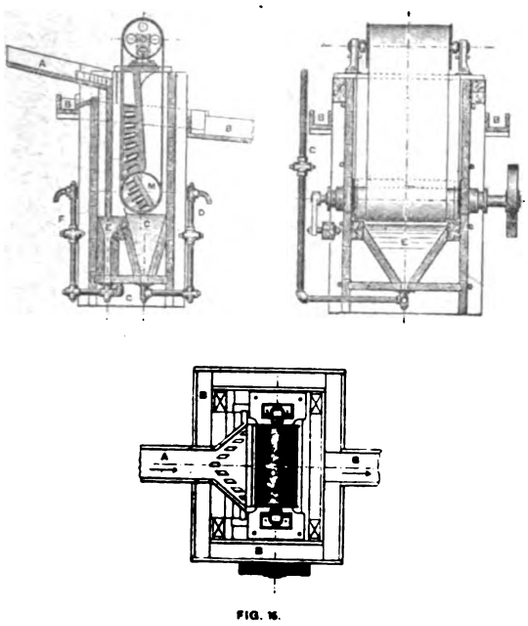

FIG. 16.

advantage be used in series where a favourable percentage of the magnetic iron might be obtained from the ore by a primary crushing of from 6 to 3 millimetres and treatment in separator No. 1, Fig. 17, the rejected portion being further reduced in size to, say, 3 to 2

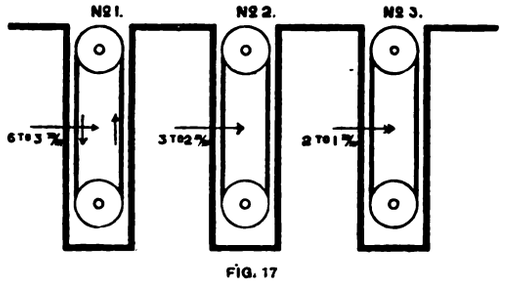

FIG. 17

millimetres, and treated in No. 2 separator, and so on with intermediate crushing between two such separators.

At Saxburget, in Sweden, where, by the kindness of Mr. Wenström, I was permitted to see their mill, they were treating an ore consisting of approximately—

	Per cent.
Lead	11
Zinc	22
Magnetic oxide...	14
Pyrrhotine (magnetic pyrites), Fe_8S_7 ...	2 to 5
Silica	15 to 20

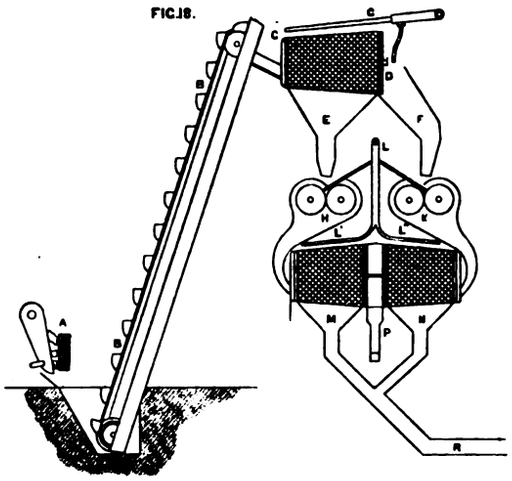
which is obtained from the adjacent Langfallsgrufvan mine.

The ore is first hand-cobbed and picked over to roughly pieces of 6 inches diameter. It is then passed on a Blake breaker, A, fig. 18, which reduces it to the size of about $\frac{3}{4}$ inch diameter. It is then lifted into the trommel, C D, provided with $\frac{3}{8}$-inch holes, by means of which the material less than $\frac{3}{8}$ inch passes through and goes on the fine rolls, H, together with water supplied by the pipe, G. Material larger than $\frac{3}{8}$ inch, or between $\frac{3}{8}$ inch and $\frac{3}{4}$ inch, passes down F to the coarse rolls, K; also with water supplied by the pipe shown. From these rolls the crushed ore passes to further trommels, M and N, provided with holes of about $\frac{1}{32}$ inch. The stuff already small enough passing down in the shape of a slime by launder R, direct to a Heberle separator of type shown in fig. 16, anything above $\frac{1}{32}$ inch is returned from F to the fine rolls, H, and re-crushed. The ore now consists or a slime containing all the minerals mentioned above, and in this state is run into the separator, fig. 16, at A. The magnetic portion is carried down on the belt and deposited into chamber C, and withdrawn by a pump through D. The coarser portion of the remainder of the mixture accumulates in E, and is withdrawn through the pipe, F, the outer case of the separator being kept full of water up to launder B by means of the water pipe, G, the finer portions of mixture consisting mostly of the blende and silica, together with about 3 per cent. magnetite, in a state of suspension, are carried away by the overflow, B, to setting pits for subsequent re-treatment as fine slimes.

The magnetite, after withdrawal from C, here disappears from the process, as, although it contains a little zinc and lead, it is found unprofitable to treat it further.

The material which collects in chamber E then goes forward to a four-compartment jig, whereby the coarser galena becomes a separated and sized product and the other products are re-ground in a special form of mill designed by Heberle, and shown in fig. 19, and consisting of two fluted plates rotating concentrically against each other, after which as much as possible of the other minerals are separated by means of pointed boxes, continuous revolving buddles, and Rittinger side recoil tables, &c.

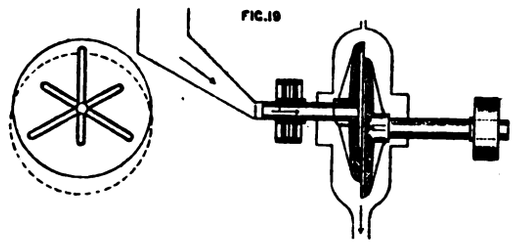
FIG.18.



5. The Wetherill Machine.

This machine has been designed to treat the ores met with at the Franklin Mines, New Jersey, U.S.A., which contain Franklinite (the chief iron and manganese bearing mineral) intimately mixed with zinc oxide and Willemite (zinc silicate) in a limestone matrix. The problem was to utilise the natural and slightly magnetic properties of the Franklinite, separate it from the admixture of the other ores, and so concentrate the zinc minerals sufficiently high to admit of their

FIG.19



reduction in the Belgian spelter furnaces. The original treatment was to roast the ore with anthracite, so increasing the magnetic properties of the Franklinite, and to treat the roasted product on a Wenström separator. Mr. J. P. Wetherill found on experiment that, by concentrating his magnetic field, the Franklinite, described by Dana as slightly magnetic, could be separated without preliminary roasting.

There are two types of Wetherill separator for treatment of ores of different grades.

Messrs. H. A. J. Wilkins and B. H. C. Nitse, in a paper read before the American Institute of Mining Engineers at the Pittsburg meeting, February 1896, gave sketches and some detail of these machines, from which it appears that the crushed and dry ore is subjected to the selective action of a highly concentrated magnetic field.

The author has had no experience with this type of machine, but there is little doubt that, in the treatment of complex ores, many of which consists of minerals described as "feebly" or "slightly" magnetic, considerable possibilities are opened up in the direction originated by Wetherill.

Messrs. Wilkins and Nitse mention "That amongst the minerals which have been found susceptible of attraction by the condensed magnetic power of these machines may be mentioned red and brown hæmatite, siderite, chromite, menaccamite, rutile, Franklinite, pyrolusite, &c. In fact, almost all minerals containing iron or manganese, or both, also salts of iron, manganese, and chromium; and with the introduction of still higher magnetic powers, it is hoped that even iron pyrites will come within the scope of successful separation treatment."

In conclusion, attention may be drawn to the increasing utilisation of magnetic iron ore, not only in this country, but to a still greater extent on the Continent, and to the growing importance of magnetic concentration as a branch of technical industry. There is undoubtedly a large field open both to the inventor and for the remunerative employment of capital, and the author hopes that these notes, as describing more particularly the Swedish practice, may not have been without interest.

THE SYNCHRONISING OF ALTERNATORS.*

By M. GARDNER and R. P. HOWGRAVE-GRAHAM.

The authors do not, in this paper, propose to deal with the manifold practical difficulties arising in the synchronising of alternators, as most of them are purely mechanical, or dependent on the individual skill and care of the switchboard attendant who is told off to perform this rather difficult and skilled operation.

This paper, then, is on the actual apparatus and methods of connection used in the synchronising of alternators, though we must first, to make the subject clearer, touch upon some of the more important points in the parallel running of alternators.

When coupling alternators so that their outputs may be combined, the conditions to be fulfilled differ in most respects from those in the case of continuous current machines.

Three conditions must be fulfilled that alternators may be run in parallel.

1. The machines must be in synchronism, that is, they must be running at such speeds that their frequency is the same.

2. They must be in phase or in step, which means that they must all give a maximum electromotive force of the same sign to the same bus bar at the same moment.

3. The voltage in most cases should be the same, but this condition is the least important of the three. In fact, the excitation of one machine is sometimes deliberately lowered to throw more load on to the others.

It is stated above that three conditions must be fulfilled that alternators may be run in parallel. The running of alternators in series was not considered, for the simple reason that alternators cannot be run in series.

It is well, perhaps, to just give a few words of explanation of this rather curious and inconvenient impossibility. We must first assume that we have got two alternators designed to give equal electromotive forces at a fixed frequency.

Let the curves A and A_1 (fig. 1) represent the electromotive force

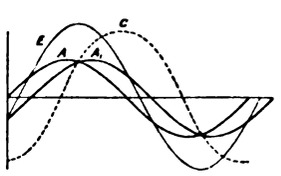

Fig. 1.

waves of two alternators with their armatures connected in series, the machines been driven independently, but so as to give the same frequencies and pressures, and suppose them to be running synchronously, but to be out of step by a small angle.

The curve, E, represents the algebraic sum of the ordinates of A and A_1, and hence represents the resultant electromotive force of the two machines.

The current curve, C, lags behind the resultant E.M.F. curve E, on account of self-induction.

Now, the total work done in the circuit equals the product of the sums of the E.M.F. and current waves respectively, that is, the product of the ordinates of the two curves E and C. The work done in the circuit by either machine equals the product of the ordinates of its E.M.F. and current curves, that is, of its E.M.F. curve and the total current curve C, which is the same for both machines.

Since the pressure wave, A_1, of the lagging machine is nearer to the curve, C, than that of the leading one, it is quite clear that the products of its ordinates, and those of the curve, C, will be larger than those of A and the curve C.

Therefore the lagging machine, A_1, is furnishing more work to the circuit than the leading machine A.

If the two machines were rigidly connected, either on the same shaft, or by other mechanical means, this condition of things would continue indefinitely.

In practice, however, the machines are generally driven by separate belts or engines, and in this case, if connected in series with the leading machine, the lagging machine, being more heavily loaded than it, tends to slow up and lag more.

Clearly the more it lags, the more work it supplies to the circuit, and by reason of this lags more still, and so goes on until the pressure waves of the two machines are exactly opposed. The machines are now in stable equilibrium, but supply no power to the circuit.

If they were started exactly in step, they would do equal work, but the least mechanical disturbance to either of them would cause it to fall out of step, as described above.

The condition of equilibrium is then unstable, and it is therefore impossible to run alternators in series, unless they are rigidly connected on the same shaft, which is in nearly every case, either of alternators in series or in parallel, impracticable.

Alternators in Parallel.

The possibility of running alternators in parallel is due to their reversibility, or ability to act as synchronous motors.

We know that an alternator connected up to another alternator which has been brought up to synchronism and voltage, will run it as a motor, and that there will be a very powerful tendency in the motor machine to keep in synchronism with the generator.

A considerable load may be put on it, and still it will keep in synchronism.

In fact, it is essential to an ordinary single-phase motor that it should be in synchronism with the generator.

A precisely similar thing happens with alternators running in parallel, for if one, by reason of mechanical or electrical disturbances, tends to slow up, the other will pump current into it, run it as a motor, and hurry it up into synchronism again. So strong is this effect, that if the machines are thrown in in parallel when they are in direct opposition of phase, they will right themselves in time, provided, of course, that they are in synchronism, or nearly so.

However, we shall return to this later on.

For parallel working the speed must be uniform, and if the cranks of the two engines are crossed, each machine will tend to alternately speed up and speed down, for when one engine pulls, the other will be at its dead point.

If the governing is not good, and the fly-wheels not heavy enough, the armature reactions will set up a kind of hunting or pumping action, and a consequent fluctuation of the lights with each period of the engine's revolution.

If the engines have two cranks, this will, of course, be obviated. More need not be said on this part of the subject, as it is not exactly within the province of this paper, and has been already so excellently dealt with by Mr. Wilson in his paper on "The Parallel Running of Alternators."

We will now pass on to the results of putting two alternators, which are out of synchronism, in series with a negligible load such as a lamp.

It may simplify matters to liken the two machines to two pendulums of slightly different lengths.

If the pendulums are started swinging in phase, they will, after a short time, get out of phase, until when one is swinging in one direction the other is swinging in the other, and similarly, in the same space of time which they took to get out of phase they will get into phase again.

Two alternators will behave in exactly the same way when they are connected in series but are out of synchronism. At one moment they will supply a voltage equal to the algebraic sum of their voltages, and the resultant voltage will be a maximum, and as time goes on, they will oppose each other, and the algebraic sum will be the arithmetical difference, therefore we shall have a minimum resultant voltage.

In fig. 2 you will see the two black curves, which represent the

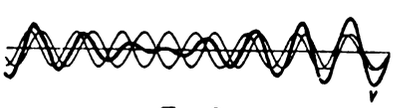

Fig. 2.

curves of two alternators slightly out of synchronism. The red curve is obtained by taking the algebraic sum of the ordinates of the two black curves, and you will see from it that the resultant voltage grows and dies away. The more nearly the machines are in synchronism the slower will the fluctuations be. This effect is very important as it is made use of in most synchronising apparatus.

We have here a model to illustrate it. A commutator and two slip rings are mounted on a shaft and revolved at a high speed by a motor. Each slip ring is connected to one half of the commutator, and has a brush pressing on it.

A continuous current is lead in at these brushes, and if two more brushes are put on the commutator at opposite ends of a diameter, we can get from them an alternating current. We have another similar commutator with travelling bearings, and it is arranged so that by sliding it along we cause a little rubber-banded wheel on it to move along a cone attached to the shaft of the first commutator. We thus have the speed of the first commutator fairly constant and that of the second variable.

We can now consider them as two little alternators, and though if connected in series with a lamp they will behave as described above, causing the light of the lamp to periodically grow and die away, either slowly or fast according to the position of the wheel on the cone, they cannot, of course, be actually synchronised because there is no sort of dynamo and motor action between them, and nothing corresponding to armature reactions.

Let us now consider the effect of throwing in two machines in parallel, regardless of step, but having got them up to synchronism first.

Immediately they are put in parallel, a current will oscillate between them, which, if they are in direct opposition of phase, may be enormous, especially in ironless armatures, in which case it will probably destroy them.

This enormous rush of current will, if the armatures stand the mechanical and electrical strain caused by it, slow up one of them a little, and they will get out of synchronism and begin that kind of see-saw action which will bring them into phase, and motor actions will start between them and bring them into synchronism. All this may sometimes take several seconds to accomplish, during which time the lights blink and go up and down.

This naturally limits the use of this method of throwing in absolutely to motor circuits, and also limits it to machines with ironclad armatures. If we were to do it in the case of ironless armatures such as Ferranti's, Mordey's, or Siemens' there would be such a rush

* Read before a meeting of the students of the Institution of Electrical Engineers on Wednesday, March 22nd, 1899.

Digitized by Google

of current as not only to destroy the armatures by mechanical shock, but perhaps to burn them out. In the case of ironclad machines, especially those with big teeth, the self-induction is so large that the current is limited, besides which all the mechanical strain is thrown on the iron and none on the conductors. Commercially, however, alternators are hardly ever thrown in in parallel regardless of step, and in the very few admissible cases it is done with ironclad armatures and motor circuits.

It may be well to mention that it is found that machines of the same type and wave form have the most synchronising power. As regards the last condition, it has been said before that slight inequality of voltage does not much matter, and is, in some cases deliberately arranged for, when it is desirable to throw more load on to one machine than on to another.

Methods of Synchronising Alternators.

The simplest form of synchronising apparatus is shown in fig. 3. A_1 is the alternator already running and connected to the bus bars. A_2 is the alternator to be thrown in. When the switch of A_2 is off

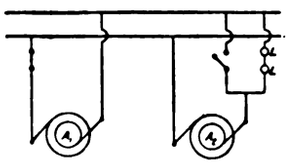

Fig. 3.

and the little auxiliary synchronising switch (which is not shown) is on, when tracing out the connections, you will see that the machines are in series with the two lamps, L L. As A_2 comes up to speed, the light of these two pilot lamps will flicker, and the flicker will get slower and slower as the speeds get more nearly equal, until the light takes about two seconds to grow and die away.

All this time the operator has been carefully regulating the voltage by means of a rheostat in series with the field coils. When the vibrations get just to the right speed, which is a matter of judgment and experience, the operator waits till the light in the pilot lamps is very nearly at a minimum, and then switches in sharply. Now, when the dynamos are out of phase as regards the synchronising circuit, that is, when the lamp is at a minimum, they are in phase as regards the bus bars, for the one is a series circuit and the other a parallel.

We have then the following condition of things when the operator has switched on:—The machines are in phase, but very slightly out of synchronism, and it has been already explained that if a machine has been slowed up a little bit, the other or others will run it as a motor, and hurry it up into synchronism, provided they are in phase. The machines will now go on quietly running in parallel. It is by no means such an easy job as it sounds, and if the man doing it switches on too late, when the machines are out of step, he may do considerable damage, and if it is a lighting circuit bring down torrents of wrath and indignation upon the heads of the company for whom he works. Even old hands seem to have to concentrate all their attention on their pilot lamps and voltmeters when synchronising, and seem to be in a sort of "Do not speak to the man at the wheel" frame of mind.

(To be continued.)

INTERMEDIATE RECEIVERS ON ELECTRICAL TRACTION ENGINES.

[COMMUNICATED.]

It is an axiom of the steam engineer that the best results from a steam engine are to be sought for only when the cylinders are dry throughout. A wet cylinder implies re-evaporation, and re-evaporation causes initial condensation. The effect is cumulative, and many engines have an initial loss of 50 per cent. of the steam admitted. A shallow thinker might demand that the steam should be so far superheated that the additional heat was equal to the missing latent heat of the quantity condensed. This is now recognised as an erroneous view. The action of superheat is also cumulative. It begins by reducing the amount of initial condensation; less re-evaporation takes place, and this means less condensation again. In the course of a few revolutions the action of superheated steam would show itself in a comparatively very large saving.

It is thus held that an initial superheat of 100° might stop all condensation. Whatever be the figure, in any one case it is clear that the steam should be dry when it exhausts to the condenser. In compound engines this is sought to be attained by intermediate reheaters. Now it is very questionable whether an intermediate receiver in a traction generator engine is a thing in the right place, and a reheater must be more or less of a receiver. Perhaps it matters less in engines of high speeds of revolution, but in slow speed engines the variations of load are so numerous and so sudden, that there must often be times when steam is cut off the high pressure cylinder by the governor and is acting on the low pressure cylinder from the receiver with an undesirable energy, for the receiver has become full of steam and proceeds to empty itself into the low pressure cylinder. This cylinder hurries round the unloaded engine at a high velocity, and forces the governor to a position beyond what is necessary, still further depleting the high pressure cylinder of steam. Then the load is thrown on by a number of cars starting on an uphill road. By this time the receiver is empty of steam, and only the high pressure cylinder is capable of doing work until the low pressure cylinder can again commence to draw from the receiver. The engine cannot run at speed; the governor throws more steam upon the high pressure cylinder, and presently the engine is full of steam, and the load goes off again just when the engine is fit to deal with it. Such, modified by fly-wheel energy, is the action of the compound receiver engine, and such, still more, is the action of the triple expansion engine.

The slower the number of revolutions in a unit of time, the more pronounced such irregular action must be.

It is assumed, of course, that the low pressure valves are fixed at about the customary $\frac{7}{8}$ths cut-off. It would almost appear that with slow speed engines the low pressure cut-off should be actuated exactly as the high pressure cut-off, or that some easily actuated throttle valve should be worked by the governor to cut off steam from the large cylinder. With such a provision there would be ready for the next load period a receiver full of hot steam to give energy at once to the large piston, while upon the load being reduced, the receiver pressure would rise against the small cylinder.

This aspect of the compound engine leads to the consideration whether the simple engine and superheating could not with advantage be employed on variable loads. The principle economy for compound working has been because of the evil of cylinder condensation which it has to some extent counteracted. But if there was no cylinder condensation nothing need be done to combat it. In a simple condensing engine there is, of course, always the accelerating influence of the condenser to deal with. If this exceeds the light load of an engine it would be possible for the engine to run away and bring into action the knock-off motion. This is undesirable, and should be met by a provision for cutting out the condenser in the same way as suggested for cutting out the receiver.

The history of electrical traction in America has been a history of many smashes, and its results have been twofold. On the one hand high speed engines have been more employed; on the other hand the low speed engines have been weighted with a large friction brake in the shape of unusually large crankshafts upon which very heavy fly-wheels have been placed to give pressure. The moment of friction has been rendered large, and the fly-wheel energy also has been made considerable. These two items between them have served to hold engines steady under the accelerating influence of the condenser at light loads. The method appears somewhat unscientific, and does not commend itself as an economical method. It is practical—this is undeniable—in fact, it is painfully practical, for it substitutes an internal power wasting brake for some means of regulation of the source of power. The benefits of condensation may be swallowed up in journal friction. It is satisfactory to find the journals of such excessive length. This has been complained of. There is no cause for complaint. Given such huge diameters, there must be great friction and consequent heat. The heat must be dissipated by a sufficient surface, and length forms a convenient means of securing surface. In slow speed engines it should be possible to regulate the energy given by the steam in place of wasting it.

THE CANDLE-POWER OF ARC AND INCANDESCENT LAMPS.*

The Appropriate Light Unit.

By Prof. WILBUR M. STINE.

The action of the American Institute of Electrical Engineers and of the National Electric Light Association in giving official indorsement to the opinion of scientists who have carefully investigated the subject, legalising the amyl acetate lamp as the standard of illuminating power, renders all forms of candles obsolete for light standards. Relinquishing the candle as the concrete light standard, should the term candle-power be given up or retained?

For illustration, suppose the meter were the legalised standard of length, and that this action was generally accepted and measurements were made with metersticks instead of foot-rules, would it be advisable to employ the ratio of the meter to the foot, and having made the measurements with the meter unit, to express the measured dimensions in feet?

* *American Electrician.*

Digitized by Google

Much the same dilemma presents itself to photometrists. Scientifically and legally, candles are no longer in repute, and the amyl acetate standard is the new unit of light strength. Shall a ratio between the amyl acetate lamp and the candle be employed and all determinations of the light strength of illuminating sources made against the amyl acetate standard be finally expressed in candle-power terms? The first step towards an intelligent decision is the consideration of the ratio between the light strengths of the amyl acetate lamp and the candle.

It has been insisted upon that experimental evidence has shown that the light strength of the candle is a widely varying and uncertain quantity. Abandoned for this reason, it is vain to seek for a definite ratio between the amyl acetate lamp and the candle, or between any constant standard of light and the candle. The numerous candle-power ratings in the literature of photometry are only mean values obtained between wide extremes, or merely figures, and represent no physical quantity. Violle, a French physicist, states the ratio as low as,

$$\frac{\text{English candle}}{\text{Amyl acetate lamp}} = 1{\cdot}02.$$

The German Physical Institute places it at 1·14, and other investigators as high as 1·22.

The term candle-power being meaningless as a quantitative expression, and the amyl acetate lamp being fairly precise as a standard light, we, in this country, might follow the example of foreign photometrists and express illuminating power in terms of Hefner units (Hefner Licht, is the current term in Germany). It might be especially desirable that the manufacturers of incandescent lamps should begin the innovation by marking their lamps in Hefner units instead of candle-power. An inconsiderable increase in illuminating power, and probably the majority of lamps would need none, would change the present candle-power ratings to conform to the new scale of:—

10	C.P.	...	...	...	...	...	12 Hefner units.
16	„	...	...	...	...	...	20 „
20	„	...	...	...	...	...	25 „
25	„	...	...	...	...	...	30 „
32	„	...	...	...	...	...	40 „

A reasonable objection to such an innovation in lamp ratings is that the change once made, a better light standard than the amyl acetate lamp might be introduced, and the necessity would arise for a second revision of lamp ratings, and so on without an end. Referring again to the analogy between this subject and the meter as a standard of length, it may be advanced that the meter is a purely arbitrary standard of length, though it was designed to be an absolute one, and for similar reasons the candle-power may be retained as an arbitrary light unit both in name and assigned value. The analogy is only apparent, for there can exist no material representation of the candle-power unit of light, because it is an indeterminate quantity. Candle-power is then a mere name corresponding to no physical quantity, and in the adoption of the Hefner unit along with the material amyl acetate standard, there is in reality nothing to relinquish but a mere custom. According to an established scientific custom, there is no inconsistency in naming the unit of light after an individual connected with its development. The custom itself, though now seemingly general and firmly established, is perhaps a questionable one. In the old mythology every aspect of nature was personified and named, and though the application has changed, the principle still survives in scientific practice.

The more rational procedure would be that followed in reference to heat. A quantity of heat is expressed in terms of heat units or British thermal units. This is thoroughly scientific, entirely satisfactory, and produces no confusion whatever. There are certain interested parties now at work, however, who are anxious to impose the name of an individual upon the heat unit, but as the change is unnecessary, it is to be hoped that engineers and physicists will be conservative and adhere to the prevailing practice and continue the use of the term "heat unit."

Let us apply the same reflections to the discussion in hand. Abandoning candle-power units and such descriptive and personified terms, let the illuminating power of all sources of illumination be expressed in light units simply. This is entirely expressive, and can lead to no confusion whatever. The value of the light unit applied to the candle, Methven screen, and such indeterminate light sources, cannot be expressed because of variations in the light strength. But applied to the amyl acetate lamp it is a quantity whose value can be stated within very narrow limits of uncertainty. As the science of light standards advances and the light strength of the actual standard becomes expressible with very great precision, the term Light Unit will still apply with equal force. If the value of the Light Unit is changed by consent of a congress or other body, it will cause no more confusion than was occasioned by the change in the value of the Heat Unit by a redetermination of the mechanical equivalent of heat.

The unit for expressing the quantity of a phenomenon must be of the same character as the thing measured, and this unit value can be no more precise than the value of the thing measured. As the measurement of the phenomenon grows more and more precise, to the same extent will the value of the unit become more definite.

Adhering still to the descriptive designation of the light unit, it has been proposed to call it the "Photon." This would be a perfectly general descriptive term applying equally to all standards. Should the term Hefner unit prove objectionable, and a descriptive unit, based on the amyl acetate lamp, be desired, following the analogy of ammeter, the name "Amate" could be coined. But applying the criterion just established, both the terms photon and amate are objectionable, it being unnecessary to employ for such purposes an intellectual cipher code.

The Incandescent Platinum Standard.—Violle endeavoured to realise an absolute or simple and reproducible standard of light by employing a definite light giving area of an incandescent metal. He finally selected platinum as best adapted for the purpose. In order that the temperature of incandescence which he used should be reproducible with accuracy, he selected the temperature of solidification of the metal. When a metal has been fused and begins to solidify, its temperature remains constant until the change of state has been accomplished. Though the same thing is true for the act of fusion of a metal, there are reasons, discussion of which would prove tedious here, why the temperature at which fusion occurs is not always the same, but varies with the past history of the metal. Platinum, in common with iron, for example, when solidifying, recalesces, or the light emitted suddenly flashes into greater brilliance, for a very short time. Violle, taking advantage of this, selected the moment of recalescence or flashing during solidification for the determination of the light strength. The mass of platinum, about 1 kilogramme, was melted by a compound blow-pipe in a lime crucible. After the fusion of the platinum the crucible was placed immediately under a water-cooled screen, pierced with a circular hole of the area of 1 square centimetre. During the flashing period the surface of the incandescent platinum was found to emit a light strength nearly 19 times as great as that of the amyl acetate lamp for the square centimetre. This standard was legally adopted, though largely hypothetical, by the Paris Electrical Congress of 1881. Subsequent experiments have not confirmed the utility of this source of light, and the attempt to realise a precise standard of light from incandescent platinum has been practically abandoned.

To Recapitulate.—The leading standards of illuminating power proposed and actually used are candles, the Methven screen, the pentane and amyl acetate lamps, and the carbon arc and incandescent platinum standards.

REVIEWS.

Analyses Electrolytiques. By A. Minet. Gauthiér-Villars, Paris, 1899.

This is the fifth text-book which the author has contributed to the "Encyclopedie Scientifique" series, edited by M. Léaute, the other four having dealt with theoretical and industrial electro-chemistry and electro-metallurgy.

The volume is well printed, and contains 170 pages and 18 wood-cuts, illustrating the text. Within this small compass

Digitized by Google

a considerable amount of information concerning the theory and practice of electrolytic methods of analysis is contained. We are afraid, however, that M. Minet has sacrificed usefulness to limits of space; and that in his desire to be brief and concise he has produced a work that will be of limited service to the student of the subject.

Electrolytic methods of analysis are of most beautiful and remarkable simplicity—on paper. In practice, however, they are chiefly notable for the amount of bad language which they produce on the part of the unlucky experimenter. And accuracy is only obtained by rigid attention to details of procedure which the novice is disposed to think of no account.

The author would therefore have done better had he devoted more space to details of manipulation and electrolytic deposition.

The arrangement of the chapters is good. Chapter I. is devoted to general principles, and to a description of the apparatus and reagents required. The author regards accumulators as the safest sources of currents for laboratory work. Chapters II. and III. are devoted to brief descriptions of the various methods of separating the metals and non-metals from pure solutions of their salts.

This is the portion of the work that might have been greatly extended, and references to the original researches upon which the methods are founded ought to have been given as footnotes, so that students might know where to turn for further information when difficulties had arisen. Not a single reference to the original literature of the subject has come under our notice in these two chapters, and this defect greatly reduces the value of the work.

Chapter IV. is devoted to details of the methods employed for the electrolytic separation of two or more metals, and Chapter V. to a brief account of the methods worked out by Holland for the electrolytic analysis of commercial copper, brass, and lead.

These two chapters might also have been greatly amplified with benefit to the book as a whole.

The facts and figures are correct so far as we have been able to check them, but surely 5 amperes on p. 107 ought to be 0·5 ampere; and the maximum weight of manganese determinable as manganese peroxide, is 5 to 7 times that stated by the author on p. 110.

The book lacks a good index.

Students and chemists may be able to obtain a general knowledge of electrolytic methods, as used in the chemical laboratory, from this small hand-book; but we doubt whether they will be able to obtain accurate and concordant results without recourse to the larger text-books of Smith, Classen, and Neumann, on the same subject.

The Electrical Engineer's Central Station Directory. London: Biggs & Son.

This directory has now reached its third edition. Like everything else electrical, it has developed considerably during the past couple of years. In a very convenient form, the principal features of the electricity supply systems throughout the country are placed before the reader, and where it has been possible to obtain them, load curves accompany the notes. A later section of the work gives some general notes under the heading "Stations Contemplated." Financial returns of certain electricity undertakings for the years 1896 and 1897, provisional orders existing and applied for, and a copy of the Board of Trade Electric Lighting Regulations complete the electric lighting section. A few notes *re* electric tramways and railways now operating and on paper, follow, and we note that there is a "Biographical Section," in which are photographs of some of our electricity works' engineers.

Schemes on Paper.—Ambitious electric railway schemes are plentiful just now. An American party talks of running an electric line between London and Brighton at high speed and low fares, while the sanguine supporters of the single-rail system propose to construct an electric line between London and York, the speed on which will be 120 to 200 miles an hour.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1889.

Compiled expressly for this journal by W. P. Thompson & Co., Electrical Patent Agents, 322, High Holborn, London, W.C., and at Liverpool, Manchester, and Birmingham, to whom all inquiries should be addressed.

16,903. "Improvements in electric ignition devices for petroleum, oil, and analogous motors." H. Guilame. Dated August 21st.

16,922. "An improved electric spark fuse." G. G. M. Hardingham. (O. R. Schulz, Germany.) Dated August 21st.

16,926. "Improvements in or relating to electric measuring and indicating apparatus." H. Darwie, E. H. Griffiths, and W. C. D. Whetham. Dated August 21st.

16,928. "Improvements in magnet separators." A. Dings. Dated August 21st.

16,956. "Improvements in or relating to conduits for electric conductors." J. J. Bate. Dated August 21st.

16,959. "A new or improved device or tool for fastening insulators for electric wires to the ceilings of rooms and other similar places." G. Dornauf. Dated August 21st.

16,960. "Improvements in rheostats and means for operating the same." C. de Kando. Dated August 21st. (Complete.)

16,980. "Improvements in or relating to electric incandescent lamps and their conducting wires, also applicable to the conducting wires of telephonic and other electrical instruments." W. Gunn. Dated August 22nd.

16,997. "Improvements in rail-bonds for electric railways and other purposes." A. J. Boult. (F. H. Daniels, United States.) Dated August 22nd. (Complete.)

16,999. "Improvements in magneto-electric telegraphs." L. G. Woolley. Dated August 22nd. (Complete.)

17,031. "Improvements in effecting contact with the active matter of accumulator plates and the like." W. P. Thompson. (C. Payen, France.) Dated August 22nd.

17,033. "Improved method of and device for switching on and off the incandescent filaments of electric incandescent lamps or the bodies serving for preliminarily heating incandescent bodies of conductors of the second class." J. Gyergyey. Dated August 22nd.

17,052. "Improvements in or connected with electric batteries." J. Y. Johnson. (Chemische Fabrik vorm. Goldenberg, Geromont & Co., Germany). Dated August 22nd.

17,130. "Improvements in automatic electric alarms." W. Ratsch. Dated August 23rd. (Complete.)

17,159. "Improvements in electricity meters." G. Hookham. Dated August 24th.

17,203. "An improvement in pole pieces for dynamos." H. A. Earle. Dated August 24th. (Complete.)

17,211. "Improved holder for telephones." W. H. Wheatley. (M. Wohlgemuth, United States.) Dated August 24th.

17,229. "Improvements in connection with the polishing or finishing of electro-plated and other articles." J. B. Brooks and J. Holt. Dated August 24th.

17,246. "Improvements in automatic electric testing apparatus." R. J. Wallis-Jones. Dated August 25th.

17,256. "Electric log recorder." L. T. Jones, jun. Dated August 25th. (Complete.)

17,257. "Improved apparatus for generating electrical pressure." G. E. Adams. Dated August 25th.

17,258. "Improvements in or relating to galvanic batteries." A. J. Boult. (J. Trillet, France.) Dated August 25th. (Complete.)

17,260. "Improved means for charging the accumulator batteries of electric motor vehicles." H. Leitner. Dated August 25th.

17,261. "Improvements in secondary batteries." H. Leitner. Dated August 25th.

17,262. "Arrangement of connections and conductors for railways worked by electricity." G. Winter and E. Futter. Dated August 25th.

17,263. "Improvements in connection with electrical measuring instruments employed in combination with current and potential transformers for measuring electrical energy." Siemens Bros. & Co., Limited. (Siemens & Halske, Aktien Gesellschaft, Germany.) Dated August 25th. (Complete.)

17,304. "Improvements in incandescent lamps for electric lighting." H. Very. Dated August 26th.

17,319. "Improvements in grips used in the laying of underground electrical cables." The Steel Nut and Joseph Hampton, Limited, and S. Hampton. Dated August 26th.

17,326. "An improved electrolytic current interrupter or circuit breaker for induction coils." W. P. Thompson. (Voltohm Electrizitats Gesellschaft A. G., Germany.) Dated August 26th.

17,337. "An improved battery cell with double case." C. Vogt. Dated August 26th. (Complete.)

17,341. "Improvements in or connected with contact apparatus for electric railways with underground current feed and mechanical partial conductor service." C. F. P. Stendebach. Dated August 26th. (Complete.)

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson and Co., 322, High Holborn, W.C., and at Liverpool, Manchester, and Birmingham, price, post free, 9d. (in stamps).

1888.

331. "Improvements in preventing sparking when making and breaking electric circuits." A. Muller and H. Tudor. Dated January 5th, 1888. Relates to improvements in preventing sparking when making or breaking electric circuits. Consists in introducing into the circuit before making or breaking the current a polarisation battery or condenser in series with the current source and the consumption apparatus to stop the flow of current before the making and breaking of the circuit." 4 claims.

586. "Improvements relating to the mounting of dynamo-electric machines." P. R. Jackson and J. S. Lewis. Dated October 7th, 1888. Relates to the mounting of dynamo-electric machines. To carry out the invention two rails are provided, laid in concrete. Between the rails at that part where the engine is to be secured is placed a third rail to act as an additional support. The dynamo is placed with its shaft parallel with the rails, and the pedestals supporting the shaft are secured to bridge pieces which are grooved on their undersides to fit the supporting rails. 2 claims.

Digitized by Google

898. "Improvements in or relating to electric illumination of railway trains." B. de Szwantowski. Dated January 10th, 1898. Relates to an arrangement whereby the force of the air currents caused by the motion of the train is so considerable, that even without a head or adverse wind the train experiences an air pressure which actually represents in strength a strong wind. The apparatus consists of a wind wheel which serves to drive a dynamo, and which is driven by a current of air produced by the movement of the train. 4 claims.

812. "Improvements in or relating to dynamo-electric machinery." P. R. Jacksen & Co., Limited, and J. S. Lewis. Dated January 11th, 1898. Relates to dynamo-electric machinery and comprises an improved construction of commutator. In the construction of the commutator the blades or segments, preferably with the radial strips attached are arranged in position with insulation between. They are then forced together so as to form a rigid cylinder. Insulation is then placed round the ends of the bars over a rebate formed on the external periphery, and a steel or iron ring is shrunk on at each end of the cylinder. 5 claims.

1,021. "Improvements in the manufacture of filaments for incandescence electric lamps." C. H. Stearn. Dated January 13th, 1898. A solution of cellulose is employed. It is made by treating cellulose with strong alkali, and then with carbon bi-sulphide and dissolving the product in water. Cellulose is precipitated in a filamentary form by projecting the solution into a precipitating solution such as alcohol. The filaments are then purified by treatment with any of the usual reagents and carbonised. 5 claims.

1,626. "Improvements in and relating to secondary batteries." W. A. Crowdus. Dated January 20th, 1898. Relates to secondary batteries in which the elements are formed by mechanically applying lead salts in the form of paste to metal plates or supports. In order to separate the plates a corrugated non-conducting separator composed for example of India-rubber. The negative plates of the battery are formed by immersing conducting plates coated with lead or oxide in a solution containing sulphuric acid and a sulphate of an easy oxidisable metal such as zinc and passing an electric current through the solution. The positive elements are first formed into negative elements and then forming them into positive elements by reversing the direction of the flow of current. 4 claims.

1,667. "Improvements in electric signalling apparatus." S. P. Thompson. Dated January 21st, 1898. This relates to the apparatus known as coherers, used for receiving electric waves in space telegraphy. Instead of using a solitary point contact or an incoherent mass of filings as heretofore, a number of discreet conductive wires are employed, arranged in series or in parallel, or in series and parallel; in light contact with means for regulating the contact pressures. Clean wires of nickel, brass, or tinned copper, so arranged, are found to work excellently. Or the contacts may be between different metals or between metal and carbon. In some cases the coherer is mounted upon a vibrating sound-board, or upon a mechanical or electric tapper, such as a clock or electric trembler. In some cases the contacts are made between stationary and revolving surfaces. 3 claims.

1,809. "Automatic switch or cut-out." E. A. Claremont. Dated January 22nd, 1898. Relates to a means for constructing a switch controlled by an electro-magnet and so arranged that on the electric current exceeding the normal the switch will be released in any predetermined time proportional to the excess of current. 1 claim.

2,167. "Improvements in and connected with electric generator for cycles and other vehicles." J. Moores and H. C. Farrell. Dated January 27th, 1898. An electric generator to be applied to a cycle or other vehicle, and driven by one of the wheels, mounted on suitable bearings or supports, on which the said generator can rock. 1 claim.

2,269. "Improvement in joints between the glass globes of electric arc lamps and the supports by which they are carried." P. H. Guerin. Dated January 28th, 1898. The apparatus consists of a globe provided with a channel forming a hydraulic or sand joint and a cylinder of a diameter to fit the recess and fixed to the sides or bottom of an electric arc lamp in order to reduce the consumption of the carbons. 1 claim.

2,427. "Improvements in variable electric resistances or rheostats." R. Waygood & Co., Ltd., and P. J. Unwin. Dated January 29th, 1898. Relates to resistances which are especially suitable for the electric starting switches for the electric motor of lifts, &c. Consists of a badly conducting powder, such as flake graphite, and a blade or plunger which is inserted more or less into it. 3 claims.

2,522. "An improved electrical striking mechanism for bells." A. Eckstein and H. J. Coates. Dated February 1st, 1898. The striker is attached by a long arm to one end of a lever near the fulcrum. To the long arm of the lever a plunger is attached. This plunger, when a current is passed through a solenoid, is drawn into it pulling its end of the lever down. This raises the striker and it hits the bell. When unenergised the weight of the hammer makes it hang nearly perpendicular. 1 claim.

2,684. "Improvements in apparatus for the electro-deposition of metals." F. Fisher, B. J. Round, B. J. Round, A. Round. Dated February 2nd, 1898. Relates to improved apparatus to be employed in the process of electro-plating. Consists of a rotating vat or vessel containing the electrolyte and the work to be plated arranged in connection with an inclined driving shaft and having an open mouth of less diameter than the closed bottom, which is provided with an attached metal ring or equivalent cathode element in connection with an outside conductor for the return current, whilst the anode element is suspended within the electrolyte in the vat by means of an adjustable and swinging rod. 3 claims.

2,761. "Improvements in high tension electric switches." E. W. Cowan and A. Still. Dated February 3rd, 1898. Relates to switches of the Hatchet type. Consists in constructing the switch with contacts in recesses and with slotted guard plates with hoods in combination with them. 3 claims.

2,784. "Improvement in electric switches." O. C. Immisch. Dated February 3rd, 1898. Relates to an improvement to prevent sparking at the switch connections. When the switch is actuated, before the existing connections are broken, the switch contact piece is first caused to establish a connection by which a path for the current is established through an electro-magnet, which as soon as it is excited, is drawn into its helix, which movement breaks the circuit. 1 claim.

3,802. "Improvements in or connected with electrical conductors." H. Edmunds. Dated February 15th, 1898. Relates to positions where only one wire may be used, but a return wire is needed. There is an inner conductor covered with lead, and that is covered with another coating of copper which acts as a return wire. The copper may be coated with an electro-deposition of gold, silver or the like to protect it. 3 claims.

3,749. "A method of oxidation and bleaching by means of electrolysis." J. G. A. Rhodin. Dated February 15th, 1898. Relates to a method for the oxidation and bleaching of textile materials by means of apparatus such as that described in Specification 21,509, 1896. In carrying out the invention the carbon anode, described in the above specification, is replaced by anode of iron or other suitable materials. The inner compartment is filled with a solution of caustic soda, the outer compartment being filled with water. The caustic soda is subjected to electrolysis with a result that the alkaline metal is by means of the mercury transferred to and absorbed by the water in the outer vessel. Oxygen is being formed and partly liberated whereby a strong oxidising agent is formed. 2 claims.

4,514. "Improvements in electrolysis and cathodes therefor." V. I. Feeny. Dated February 23rd, 1898. Relates to the cathodes for electrolysis. Consists of covering the cathode with a layer of sulphide and polishing it. The deposited metal can then be easily removed by breaking or brushing. The metal broken away is polished. The sulphide of the metal cathode may be obtained by rubbing the metal with sulphur and water. 3 claims.

4,624. "The electrolytic manufacture of alkaline bichromates." J. Heibling. Dated February 24th, 1898. Relates to a process for the electrolytic manufacture of alkaline bichromates. The process consisting essentially in subjecting to the action of an electric current by means of anodes of chromium or alloys of chromium, a solution of alkaline chlorides contained in an electrolytic vat. The same result can be obtained by employing a solution of alkaline nitrates, and the process can also be carried out by using as the electrolyte a solution of caustic alkali. 8 claims.

5,034. "Improvements in or relating to electrolytic meters." C. O. Bastian. Dated March 1st, 1898. Relates to electrolytic electrical meter. Consists of a glass frame or open work support with thin sheets or surfaces of platinum or equivalent material mounted opposite one another on the frame so that they cannot come in contact, and means to attach the sheets to the frame two vertically extending glass tube connected to the frame, and two conductor wires in said single tube and passing out therefrom, and respectively connected with the circuit wires and the platinum sheets. 11 claims.

5,279. "Improvements in the manufacture of submarine telegraph and telephone cables." W. T. Henley's Telegraph Works Company, Limited, and G. Sutton, and L. L. Hartelgson. Dated March 4th, 1898. Relates to a protective covering for cables. Consists of a protective armouring of two open windings of galvanised iron or steel tape, the second winding covering the intervals between the convolutions of the first. 1 claim.

6,147. "Improvements in the electrolytic treatment of ores and slimes for the recovery of precious metals therefrom and apparatus therefor." H. Rieckes. Dated March 12th, 1898. Relates to the electrolytic treatment of ores and slimes for the recovery of metals, chiefly gold. Consists of an open vat made of wood lined with copper at the sides and bottom. The copper is silver-plated. The sides are inclined. At the bottom is a trough for the collection of mercury, and at the top a perforated pipe for distributing the mercury over the sides. The gold forms on the copper sides over which the mercury flows. The anodes are of carbon fixed to a shaft which traverses the vat and which is rotated or oscillated by any suitable means. It is connected to the + pole of a dynamo, the lining of the vat being the − pole. 6 claims.

6,981a. "Improvements in index needles or pointers for electrical and other indicating or measuring instruments." E. Weston. Dated March 22nd, 1898. Relates to index needles. Consists in having short arms running radially from the pivot and attached to the pointer, so that specially constructed nuts can be screwed on to counterbalance the weight of the needle. The arms are at right angles so as to form a cross with the needle for the longest arm. The whole is made of aluminium so as to give lightness. 20 claims.

6,982. "Improvements in electrical measuring instruments." E. Weston. Dated March 22nd, 1898. Relates to improvements in electrical measuring instruments. Consists of an electrometer provided with a stationary electrostatic field and a movable electrostatic armature or needle adapted to move in said field in combination with an indicating needle attached to or carried by the electrostatic armature or needle, a calibrated scale, and an independent indicating needle all enclosed in a casing, the independent indicating needle being provided with means extending through the casing for moving it by hand to any predetermined point whereby comparative reading may be taken at a distance. 22 claims.

8,439. "Improved means for electrically heating second class electric conductors serving as incandescence bodies for imparting to them the requisite conducting power." M. Deri. Dated April 23rd, 1898. Consists in the employment of an electrical heating body of very weak conducting power, so as to offer so great a resistance to the current that the resulting heat will be transmitted to the conductor of second class, constituting an incandescence body surrounding the heating body, for imparting to this the requisite conducting power. 1 claim.

10,225. "An improved method of casting electric accumulator plates and apparatus therefor." J. Heese and J. Kernaul. Dated May 4th, 1898. Relates to the casting of accumulator plates having tapering projection on them to hold the active material. The ridge plates are cast in the form of an arc or circle instead of casting them directly as desired, and, after casting, bending them into a straight shape. 3 claims.

14,833. "Improvements in and connected with junction boxes for electric cables, inspection chambers and the like." F. Franklin. Dated July 6th, 1898. Relates to ventilated junction boxes which prevents dirt or wet getting in. Consists of a frame having a flange adapted to rest on brickwork, and a channel surrounding the upper part. Holes are formed in the channel. A cover fits on the frame and has ventilating outlets round the edges. To prevent water entering through these a bead is cast round the underside of the cover. 3 claims.

15,886. "Improvements in electro-magnetic ore separators." H. Langguth. Dated July 20th, 1898. Relates to electro-magnetic ore separators in the form of a wheel or rim, consisting of a single rotary electro-magnet with cylindrical or pan-shaped poles of U section situated opposite each other. 2 claims.

16,246. "A new or improved electric sounding device." J. P. Buckley and W. A. Creffert. Dated July 26th, 1898. Relates to long distance sounding apparatus for ships. Consists of a shell or casing containing a liquid contact maker and connected by electric wires to an alarm device, *viz.*, an adjustable float and adapted to be suspended without giving an alarm and when not or only partially suspended to give an alarm. 3 claims.

17,418. "Improvements in or relating to electric tumbler switch appliances and their base plates." C. Markt. Dated August 12th, 1898. Relates to improvements in electric tumbler switch appliances. The base is made of pottery and is provided with two raised cheeks in which screw holes are formed. Two pockets separated by a pocket into which during one operation of the switch the tumbler goes. The contact piece of the switch works upon a hinge and is held up by a spring. The lever is also on a hinge and is not fixed to the tumbler but is provided with a wheel which runs along the tumbler pushing it on to the partition between two holes in the base which is a contact piece. 5 claims.

18,531. "Improved means for electrically operating electric railway switches." R. A. Baldwin and H. Rowland. Dated August 29th, 1898. In carrying this invention an electro-magnet is located in a box in the roadway at some convenient point adjacent to the switch tongue. Current to actuate the magnet is taken from the return circuit of the railway which ordinarily is the rail. In order to do this, a short section of the rails ahead of the switch is insulated, and when the switch is turned the return circuit from the vehicle is passed into the insulated section of the rails then to the magnet and finally to the return circuit. 5 claims.

18,796. "Improvements in and connected with secondary or storage batteries." W. M. McDougall. Dated May 13th, 1898. Secondary batteries are arranged so as to minimise the vibration when mounted on vehicles and the like. The electrodes are made with projecting bosses in which are cut intersecting grooves reaching to the surface of the plate. The plates are covered on both sides with sheets of insulating material in which are holes to receive the bosses, and the sheets are of such a thickness that the bosses lie flush with their outer surface. Division plates are also placed across the electrodes. The plates are made of insulating material, finely perforated and with ribs on one side only, these ribs being turned towards the negative plates in the battery. The bosses may be replaced by projecting horizontal strips or webs, the spaces between which are filled with lead dust. 3 claims.

18,940. "Improvements in alternating current arc lamps." C. D. Abel. (H. O. Swoboda.) Dated September 5th, 1898. Relates to arc lamps in which the vibration of the feed magnets under the action of the alternating currents will not be transmitted to the lamp. 6 claims.

19,248. "Improvements in alternating current electric motors." W. P. Thompson. (C. S. Bradley.) Dated August 30th, 1898. Relates to electric motors having one core or element wound to produce a rotary magnetic field when supplied from a single-phase alternating current circuit, and a secondary core or element having its winding connected with an adjustable phase advancing device such as an electric condenser. 2 claims.

20,989. "A new or improved composition for electrically firing detonators." G. P. Bickford-Smith. Dated October 5th, 1898. Relates to a composition consisting of potassium chlorate, precipitated copper, precipitated silver, antimony sulphide, electrotype plumbago, and sodium tungstate in certain proportions. It is fired in a casing by an electric spark. 1 claim.

THE SWISS REUNION AND ITS LESSONS.

Now that the visit of the Institution of Electrical Engineers to the industrial districts of Switzerland has taken its place amongst the proceedings of the past, the time has come to consider what we have learnt as the result of our investigations. Various questions arise of great interest and importance. We will select for consideration the following:—Are we falling behind in the march of electrical engineering progress? If so, what are the causes of our backwardness, and how can they be removed?

We are immediately struck by the fact that the conditions prevailing in this country are not comparable with those existing in Switzerland. In that rugged country an abundance of water-power has taken the place of a natural supply of coal. There is a grand similarity between the two great processes of storage: here we profit by the solar energy stored up countless centuries ago in the form of chemical energy; there the process is in progress before our eyes, as the moisture raised by the same agency crystallises on the mountain tops and stores up potential energy, to be gradually released by the melting of the snows. But there is this important difference between the two cases—that water-power is not commercially capable of transportation over great distances without transformation into some other form, while, on the other hand, it is easy and profitable to convey the coal itself with its store of energy to the place where power is required. Moreover, the localities where water-power is most abundant in Switzerland, are frequently, for the same reason, unsuitable for the sites of factories and towns. Hence arose the need of a system of transformation and distribution of energy over considerable distances, with great flexibility and economy in capital cost. The first attempts in this direction took the form of rope transmission, which in no other place attained to such a high degree of development; but the advantages of electricity soon made themselves apparent, to the exclusion of all other agents. At first, direct current and single-phase alternating currents were employed, but the difficulties attendant respectively upon the use of high pressure direct current commutators, and of synchronous alternating current motors, were such that upon the introduction of polyphase working its superiority was immediately recognised. The simplicity of the machinery, the ready handling of the motors, and the low first cost of the line—a most important factor in this case—were too obvious to be overlooked; and the natural consequence was that the most rapid development took place in the direction of polyphase working, which, in Switzerland, is practically confined to the three-phase system. The adoption of the same system for lighting was due to the desire to avoid the use of the complicated moving machinery which is inseparable from the conversion of alternating into direct currents; some trouble was at first encountered on

Digitized by Google

the score of regulation, but this was practically overcome by the use of a neutral or return wire for the lighting circuits, and now the three-phase system is almost universally used for the Swiss lighting circuits, the exceptions being small isolated installations, where the advantages of storage are important. Most of the tramways, it is true, are still worked by direct currents, generally obtained from a three-phase plant with rotary converters; but that there is no bar to the application of the polyphase system to traction has been completely proved by the pioneer work of Messrs. Brown, Boveri & Co.

Now, in Great Britain the supply of motive power has been up to the present an almost negligible factor; lighting has always been the chief consideration, and has been carried out by isolated installations close to, or in the midst of, the area supplied, hence there has been no need of transmission over distances exceeding two or three miles at most in the majority of instances, and even where the distance has been greater, the absence of a demand for motive power has permitted single-phase currents to meet the circumstances sufficiently well. Consequently, the line of development in this country has been that of direct and single-phase working, in both of which branches we hold our own as regards the excellence and magnitude of the generating and transforming plant. Long-distance transmission, and electric supply on a polyphase system, are absolutely non-existent here; even those schemes which are projected for transmitting power over some considerable distances are intended to use polyphase working for transmission only, and to distribute with direct currents.

We conclude, then, that we are many years behind the Swiss in the manufacture and use of polyphase machinery, while they lead the world in this department; nevertheless, we are at least abreast of them in the construction of direct current and single-phase machinery. Their turbines are unexcelled; but so are our engines and boilers. The remarkable progress which they have made in the special branches enumerated above must be in great part ascribed to the natural conditions of their environment, and we have seen no cause to suppose that our less forward state is due to any deficiency in the talent or inventive genius of our engineers.

There is, however, another aspect of the question, and this is, to our mind, by far the most important one. We refer to the economic view. Apart altogether from considerations of environment and engineering skill, we have observed the attitude which the capitalists, banks, municipalities, and the public generally have taken towards the development of electrical engineering and its dependent industries; and here we find a startling contrast with the state of things in Great Britain. We are accustomed to see our councils rising in their might to repel the so-called "monopolist," to resist great schemes for distribution of power over large areas at minimum prices, and to crush all native progress. We have seen them act the part of the "dog in the manger," securing powers to provide electrical supply, absolutely in order to prevent such supply being given! We have seen our great companies starving for capital, unable to carry out the extensions so urgently needed, while foreign-made machinery is pouring into our ports. No sooner is a tramway or light railway scheme projected than immediately meetings are held to devise ways and means to oppose the undertaking, often with a view of being bought off at ruinous prices—a process generally known as jobbery, to use the mildest term. We see our municipalities imposing arduous and unjust conditions on British contractors, and simultaneously giving orders abroad without a thought of controlling the wages there. The parrot-like cry of "disfigurement," so long cast in the way of tramway schemes, is happily becoming rare, as the public learns that the good of the many ought not to be sacrificed to the prejudices of the few; but still we see London destitute of electric tramways and our toilers crowded in mephitic tunnels, 15 to the compartment.

In Switzerland there is nothing of this. Far from opposing engineering projects, the people welcome such, knowing the advantages that are certain to accrue to them; capital flows freely into the industry, and the far-seeing directors of the great banking concerns support the schemes. The beautiful and picturesque streets of the towns and villages, the inter-urban roads, and even the mountains themselves, have their well-laid tramways, operated for the most part by water-power.

High pressure transmission lines of bare copper wires on porcelain insulators are commonplace; they are met with everywhere. Yet our Board of Trade will not so much as sanction a few miles of overhead conductors in country districts between villages and townships, at one-fourth the pressure used by the Swiss, but requires costly underground mains, which weigh down the undertaking with excess of capital, like Sindbad's "Old Man of the Sea." Our electrical industry is cramped and fettered by the restrictions which bind it; were it not so, we should soon see great distribution schemes, power transmission over long distances from the coal areas, and even full-gauge railways, electrically operated, as in Switzerland.

How to remedy these evils? "There's the rub"; it is not easy to reach the roots of the canker. Many maintain that technical education is the great panacea; we are convinced that this is but a minor factor in the problem. We went to Zürich honestly looking forward to the visit to the Polytechnikum, prepared to admire, and schooling ourselves to control our anticipatory feeling of envy. We came away with a sense of disappointment. The physical, or more properly, the electrical engineering, laboratories of which we had heard so much, were superior to those of our own technical colleges in but one respect—they are generously supplied with funds by the Swiss Government, whereas our own are dependent on a confused variety of grants, donations and private endowments, and are always starved for up-to-date apparatus and equipment. The methods of teaching are no better than our own; the apparatus, thanks to the ample funds, looks newer and better made (much of the most modern apparatus in our colleges is made by the students—and demonstrators, when they have time, which is seldom), but the type of apparatus is old-fashioned. The tangent galvanometer dominates the department; we saw but one d'Arsonval, and that was of the old pattern; scales are read with telescopes, a method regarded by us as tedious and primitive; alternate current wave forms are plotted with ballistic galvanometers and condensers. We do not wish to convey the impression that the laboratories are inadequately equipped; but we are convinced by actual observation, that our own are at least as well adapted for their purpose, and are in many respects in advance. We paid a visit to the mechanical engineering

Digitized by Google

laboratories, and found them *half-built*; we inspected the designs, which were admirably complete, but up to the present, we find, there has been practically nothing of this kind. Here we are a long way ahead. The most noteworthy feature of the system of education was, in our opinion, the fact that the students pass two years in workshops, as apprentices, *before* they commence the course of technical instruction at the Polytechnikum. We heartily commend this practice to the notice of our authorities.

Our conclusion is that technical training is not the solution to the problem. We believe that the only possible cure lies in the education of the people of Great Britain; teach them to realise that the prosperity of the nation can only be maintained by constant progress, and to understand the irreparable injury already inflicted upon our commerce and prestige by the blind reactionary opposition to all new things, so characteristic of the British public now a days. Let our daily press take up the work, and drive in the lesson by constant repetition—it is their peculiar privilege to reach the mass of the people as no purely-technical journal can. The British nation is at fault, not the engineer; let the nation encourage and support the engineering industry, instead of striving to restrain its progress—let it learn from the gallant little Swiss Republic how to aid and cherish scientific enterprise, on which the prosperity of Great Britain depends!

PROVIDING FOR ELECTRICAL SUPPLY DURING HOURS OF SMALL DEMAND.

The financial success of the supply of electrical energy may be considered to depend to a considerable extent on the maximum and minimum loads on the plant.

A statement of the total output from any works for a whole year does not reveal any indication of the peculiar conditions of electrical supply; but when the actual capacity of the plant is considered, or, in other words, the total possible output in one hour, it seems surprising that, as a rule, the yearly output could be generated in one month. In many works the plant could in three weeks generate sufficient supply for one year's demand, and even if it were commercially practicable to store up this output, ready for sale when wanted, it may well be doubted if a consecutive idleness of 49 weeks in the year would prove beneficial to the plant.

Machinery, with or without storage batteries, must be provided for the maximum load, and as this load is absolutely under the control of the consumers and can be estimated with considerable accuracy, it becomes possible to provide generating plant and storage in such proportions as will ensure a constant load on the steam plant for many months in the year, an economical load during the summer months and during hours of small demand. This is, of course, no new principle, and long before the secondary battery left the laboratory to become an engineering appliance even more ambitious claims were made for its practical utility.

The capital cost of this method of equalising the load on electrical plant has hitherto been almost prohibitive, and though the present cost of batteries is a very serious item, there is so much to be gained by their use that a liberal interest on the capital outlay may be realised.

The use of storage batteries in this manner must of course be confined to continuous current distribution, and it is probable that existing systems of alternating current supply may with advantage undergo a gradual change to continuous current.

In the meantime, distribution by alternating current does not possess many facilities for securing economy during hours of small demand. The sub-division of plant into machines of convenient variety of size is not an easy matter, for if the works are designed for parallel running, it is difficult, if not impossible, to secure a proper division of the load; and if circuit running is adopted, serious trouble is caused by throwing load from one large machine, say, on to several smaller machines. It, therefore, appears that to secure economy in alternating current generation during hours of small demand—probably 80 per cent. of the year—it is desirable to arrange for a separate plant of high efficiency and durability, fed by separate boilers through short steam pipes.

The Electrical Units.

We recently noticed an article in the *Electrical World* (New York), advancing proposals for a change of nomenclature of the electrical units in such a way that the name of each derived practical unit should denote what multiple or sub-multiple it is of the fundamental unit. We expressed an opinion that the gain derived from such a change would not compensate for the incidental temporary confusion, though if any fundamental change in definition were contemplated, such as the introduction of the Heavisidal units, the system of names proposed by our contemporary would be worth careful consideration. The publication of this article in the *Electrical World* has induced M. A. Blondel to publish at once in *l'Industrie Electrique* an article on the same subject, advancing very similar proposals, which he had prepared for the approaching meeting at Boulogne of l'Association Française. M. Blondel proposes two changes:—(1) To transfer the names ampere, ohm, &c., to the C.G.S. units, each with a temporary prefix to be afterwards dropped. Thus for the present he would call the C.G.S. unit of E.M.F. the neo-volt, and as soon as the system was well established it would be called the volt; (2) For practical purposes to use only three sub-multiples, and three multiples, of the units with the prefixes micro, hypo, milli, kilo, hyper, mega; hypo meaning that the fundamental unit is multiplied by 10^{-9}, hyper by 10^{9}, micro by 10^{-15}, mega by 10^{15}, milli and kilo retaining the present senses. We may refer our readers who wish to study M. Blondel's proposal closely to the French journal, in which the question is discussed at considerable length. There can be no doubt that his system would have advantages over our present one. Names for the C.G.S. units would be very useful, and the new multiples and sub-multiples would bear their descriptions in their names. M. Blondel, moreover, thinks the new derived quantities would be more convenient than the old practical units, but we doubt this. If we are to have a change at all let us have the rational units, and a revision of nomenclature may come at the same time as a subsidiary reform.

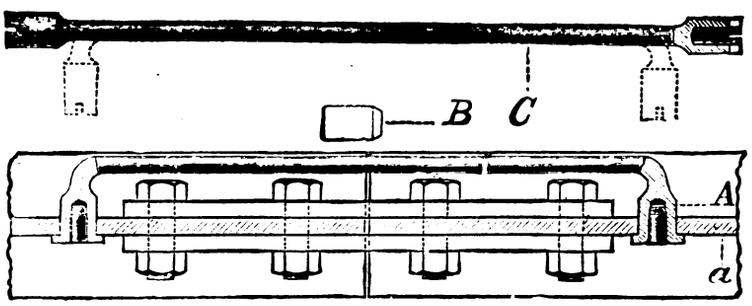
INDISPENSABLE ACCESSORIES OF ELECTRIC TRACTION.

By HENRY E. P. COTTRELL, A.M.I.C.E.

(*Continued from page* 387.)

The last or "uniform" sub-division comprises only one bond, which is known as the "Chicago Crown" bond, and is manufactured in two forms, viz., rigid and flexible. The

The "Chicago" Rail Bond.



Sectional View.

Elevation View.

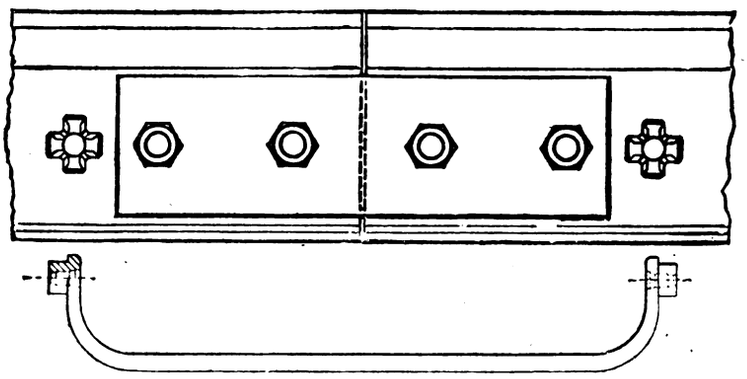


Fig. 90.—"Chicago Crown" "S" Solid Bonds.
For bonding at points and crossings and between tracks.

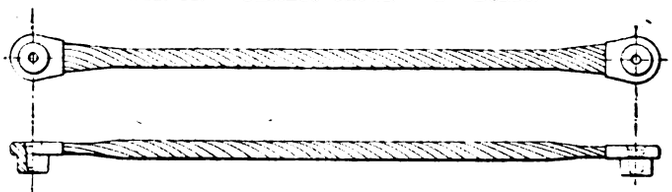
first form belongs exclusively to the group of long exposed bonds, while the second form belongs to both Group A and Group B. The "Chicago Crown" rigid bond (fig. 90) is forged from a single solid piece of copper, the thimble-shaped terminals having tapering conical perforations of a special shape. When the terminals are inserted in the web holes they are secured by expanding one end of the perforation with a tapering punch, then a tapering drift pin, $\frac{1}{16}$th of an inch larger than the holes, is driven home, the terminals expanded and a lip formed at the smaller end, as in a rivet head. The contact between the iron and copper, in consequence of the pressure thus exerted, is so intimate that it can never be rendered less perfect by working loose, by corrosion, or by electrolytic action. The area of the contact surface is over 11 times the sectional area of the copper bond uniting the terminals. The resistance of these bonds when both terminals and web holes are very clean is under 2 microhms (per two terminals in series), while their conductivity is practically 100 per cent. of that of pure copper. The effect upon the resistance offered by this practically perfect bond, when the web holes are oily or oxidised, or both, is most marked and runs it up to four times the minimum, or 8 microhms (*vide* Mr. Parshall's experiments).

The "flexible Chicago Crown bond" (figs. 91, 92A and 92B) is made both in the long type and in the short type; its terminals are identical with those of the rigid form, and it is fixed to the rail in identically the same way. The difference lies in the portion connecting the terminals. This consists of strands of copper wire laid crossing each other at an angle, which provides for expansion and contraction in the rails without sensible alteration of shape, and allows the bond being fitted without difficulty to the rails at any temperature. The terminals and strands are united by a special process of forge welding, and the union is so perfect that when sawn through the weld the strands are found to have lost their identity, and the whole is a homogeneous mass of copper, and capable of standing to all intents and purposes the same tensile tests. The conductivity of the bond is upwards of 93 per cent. of that of pure copper, which with the same effective cross section of web ($\frac{1}{2}$ inch), and contact area with rail web (1·37 inch), and clean condition of bond and holes as the rigid bond previously described would give a resistance of $2\frac{1}{8}$ microhms (per two terminals in series), or an increased resistance of only $\frac{1}{8}$th of a microhm to set off against the advantages of flexibility and adaptability. The fact of its being made in the short or covered type has the further advantage of enabling the initial cost of the bonds to be greatly reduced. It is interesting to note that Mr. Parshall found the conductivity of the Columbia multiple bond to be only 90 per cent. of that of the Chicago Crown rigid simple bond, while its resistance was from $3\frac{1}{2}$ to $4\frac{1}{4}$ times as great, the bonds being identical in every other respect; this shows how essentially superior the simple uniform bond is when compared with the best examples of the multiple monometallic varieties, and *a fortiori* any other multiple varieties.

The third method of bonding is the one which dispenses entirely with added bonds and ordinary fastenings by the substitution of a special joint, or by the total abolition of all joints. The first process is known under the name of the cast-welded joint, and the second as the endless electric welded rail. The conditions of expansion and contraction of the rails on a railway and a tramway are entirely different; in the former, the rails are practically wholly exposed and wholly free to alter in length in accordance with the changes in temperature, while in the latter they are to a great extent protected and prevented from moving by being embedded in the pavement.

The skin friction between the rails and the pavement and the weight of the latter is so great, that even in extreme climates the contraction or expansion, due to variations in the atmospheric temperature, produce hardly any perceptible movement in tram rails, and practically no allowance need be made for contraction or expansion in laying a tramway track. The only precaution that need be taken is to avoid unbedding much track at one time for repairs in the summer time, should the track in question happen to have been laid in the winter, or *vice versâ*, otherwise "hogging" may take place in the first case and ruptured joints in the second. In a tramway, therefore, the ideal track without joints, so

Fig. 91.—"Chicago Crown" "F" Bonds.



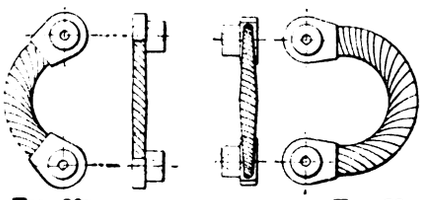


Fig. 92B.
Stranded "Chicago Crown" Bond, Style "T."

Fig. 92A.
Stranded "Chicago Crown" Bond, Style "U."

desirable both from the mechanical and electrical points of view, seems to be a practical possibility. Electrical welding has for several years been the subject of extended experiments in the United States of America, but so far the results have not been such as to encourage tramway companies to adopt this system of bonding. Its drawbacks may be summarised as follows:—

Digitized by Google

1. Decreased conductivity of the welded portion as compared with the rest of the rail. 2. Increased temper and even wear. 3. Excessive cost of process as compared with other methods of bonding.

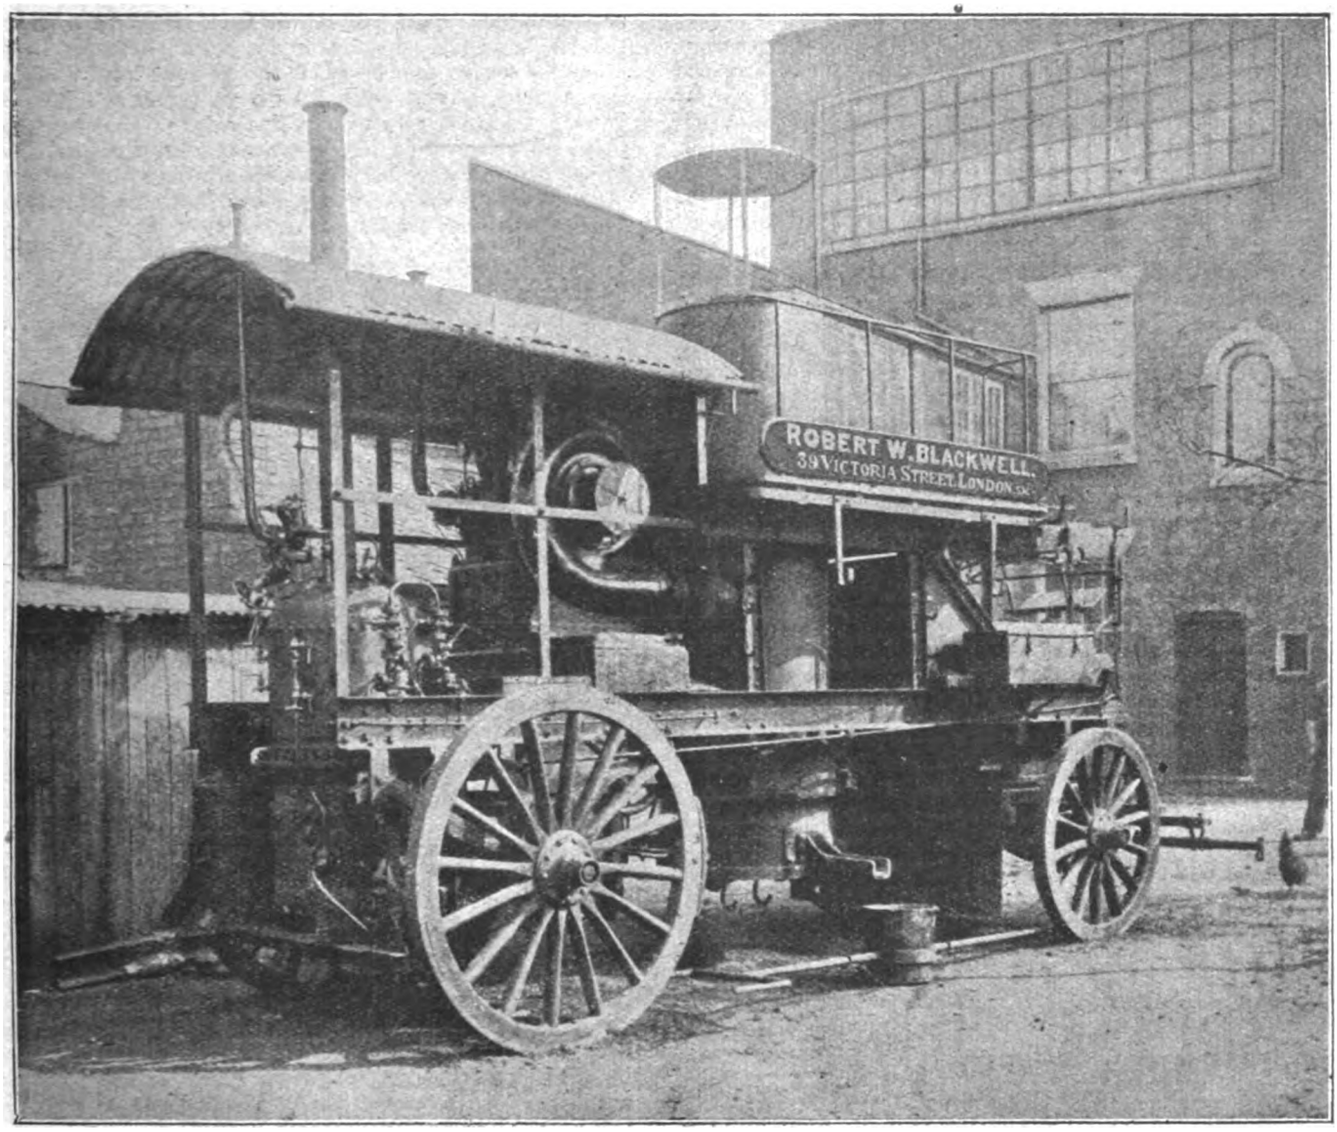

Fig. 93.

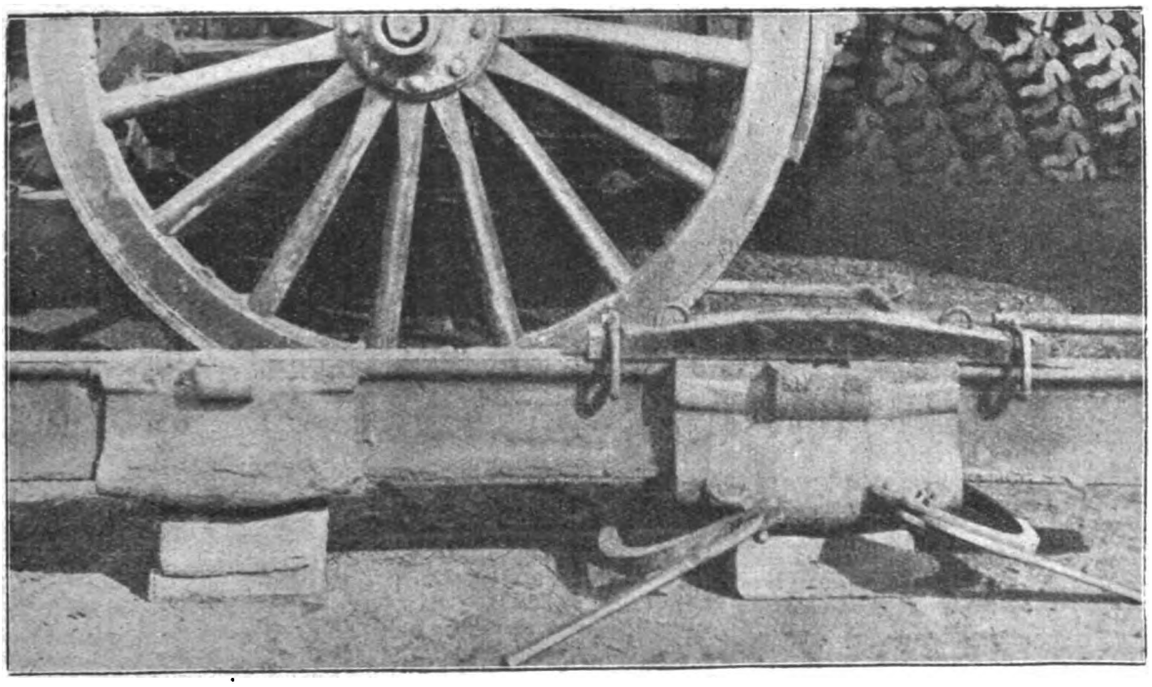

Fig. 94.

brittleness of rail at weld, softening of adjacent portions, and consequent increased liability of rails to fracture and to un-

The apparatus required for electric welding is costly, and in practice the required power is not always easy to obtain,

Digitized by Google

so that although the drawbacks mentioned above might no doubt be removed with more extended experience, still it is not to be wondered at if the process has not as yet been tried on this side of the Atlantic.

The cast-welded or "Falk" joint has, on the contrary, been extensively tried in England, both at Coventry and Norwich. By this system the joint is done away with by casting a cast-iron sleeve round the sides and bottom of rails at their joints. A metal mould is fixed round the rail ends, a special mixture of cast-iron is run into this from a portable cupola; the molten metal cooling rapidly in contact with the mould, shrinks, exerting great pressure on the embedded rails, ensuring a thoroughly good mechanical joint and electric bond. The size of the joint is such as to ensure the same tensile strength as in the remainder of the rail. These joints are generally 14 inches in length, and from 70 to 140 lbs. in weight, proportionately with the weight of the rail. Figs. 93, 94 and 95, show the movable cast-welding plant, a joint with mould in position for casting, and a section through a cast joint respectively, as carried out by Robert W. Blackwell and Co. at Coventry and Norwich. This joint has been undoubtedly a mechanical success, owing to the slight clearance

Fig. 95.

afforded by the contracting of the rail after the cast sleeve has set being just sufficient to admit of a slight play for contraction and expansion in the rail ends. But this clearance, though of the slightest description, accounts for the variations that have been observed in the electrical resistance of the joints when new, and will probably cause this to sensibly increase with time by the deposition of a slight film of oxide between the cast-iron sleeve and the embedded rail ends. On the whole, however, this system of doing away with rail joints has been undoubtedly a great success, its only drawback being the question of cost, this being specially noticeable where the casting plant has to be brought into operation for a few joints at a time, such as occurs when small extensions or repairs have to be carried out, especially in this country, where only two or three yards of road can be opened at once. It has been practically demonstrated that unless one mile of street can be opened up at a time the cost of each joint is very great.

THE INSTALLATION OF STEAM BOILERS.

VII.

So far the structure of the boiler has chiefly been dealt with. Before dealing with the fittings, we may take a brief glance at the question of the brickwork in which the boiler is built. It is almost superfluous at this date to insist on the necessity for absolute dryness of foundations, and if only a damp site is available, it becomes necessary to construct a tank of sound concrete, rich in cement, and put in sufficiently wet to be waterproof, and of such size as to be removed from the effect of the heat by sufficient thickness of bricks. Under the most careful construction in such cases the concrete floor should have a fall to some accessible sump, or water catcher. Failing a dry foundation, the moisture creeps up the brickwork of the seating walls, and causes severe corrosion of the plates along the line of seating.

Years ago, when no care was exercised as to the selection of the site of a boiler, explosions from this cause were frequent. This class of explosion has nearly disappeared. In ordinary practice, as developed by long experience, a boiler is set upon two longitudinal walls, parallel to one another, and distant apart over half the diameter of the boiler. On these walls are laid specially formed seating blocks of firebrick, the seating edge of which should not exceed 8 inches in width, and may advantageously be convex in profile so as to touch the boiler plate along a line only. Where the ring seams cross the seating blocks, a rectangular gap should be cut across the seating for purposes of inspection, and specially formed wedge pieces ought to be provided to close these gaps. These are removed for inspection, and at once replaced.

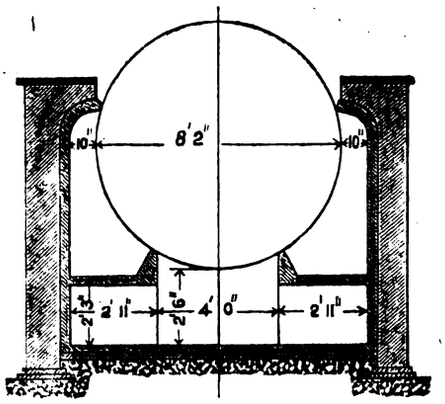

Fig. 19.

The course followed by the gases issuing from the furnace tubes is first along the bottom flue, and this flue should be from 27 inches to 30 inches deep below the extreme bottom of the boiler. This depth admits of convenient inspection. Any much greater depth prevents a convenient seated inspection, but there is no objection to a very deep bottom flue if circumstances render this desirable, in which case the depth should be such as to permit of a standing inspection. The reason for the bottom flue being the first taken by the gases is that the bottom of the boiler may be kept as warm as possible. When the side flues were kept the hotter, the riveted seams on the boiler bottom were liable to be torn. This was known as the seam rip and was due to unequal expansion between the upper and lower parts of the boiler.

The formation of the side flue should be such as to admit the very easy passage of a man with full liberty to inspect along both seat and flue cover lines of contact. The use of

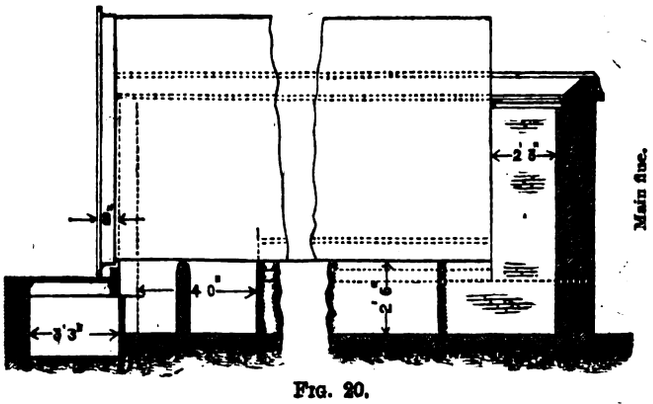

Fig. 20.

the specially formed seating block allows an ample space along the bottom of the side flue, the outer wall of which should not be less than 9 inches clear of the boiler at its horizontal diameter. The side flue covers are quadrants of a firebrick cylinder 8 to 4 inches thick, and these may with advantage be convex on the face next the boiler plate. These covers may be placed about 6 inches above the level of the furnace crown, but there need be no fear, if it is thought desirable, of completely arching in the boiler crown so as to admit the gases over practically the whole crown in a space of 4 inches thickness. It is most essential that all the brick

Digitized by Google

work, especially of outer walls, should be sound and air-tight. For this end the front wall should be faced with glazed bricks set in cement, and any exposed side wall should be repeatedly tarred or painted to render it air proof.

Where boilers are set in batteries, the dividing wall between the side flues of contiguous boilers should not be less than 9 inches thick, and all flue walls must be internally lined at least 4½ inches in fire brick. Division walls may be 13½ inches if there is enough ground area to permit of this. The back down-take admitting from the furnace tubes to the bottom flues is often made 27 inches wide from the boiler end plate to the back wall. This is a fair allowance, but it may well be made 30 inches if space permits.

It is usual to build a mid-feather wall to divide the streams of gas from the two tubes, such mid-feather continuing a couple of feet along the bottom flue. Unless the

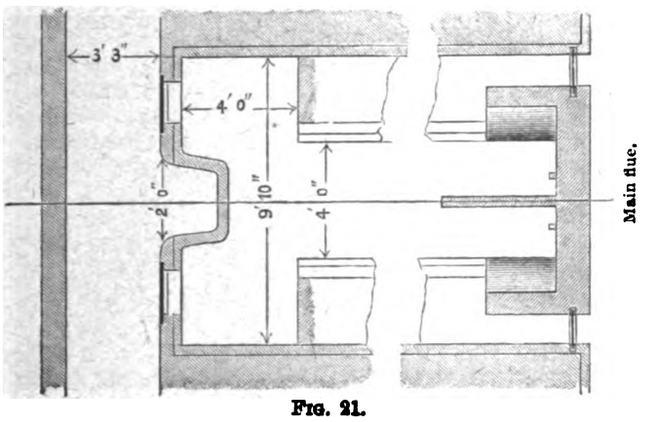

Fig. 21.

boiler is at least 90 inches diameter, anything over 4½ inches thick is rather in the way, while a 4½ wall is very short lived. A mid-feather is often advantageous in preventing a tremulous draught. A bituminous coal cannot be smokelessly consumed where the draught is tremulous. The best covering to these rear down-takes is a larger quadrant tile of the same type as the side flue cover tiles. These will prevent a tremulous draught where one has existed with a flat topped down-take. But by far the most convenient down-take cover is a flat plate of cast-iron fitted in a frame built above the down-take. The flat plate can be lifted by the usual T head key and access gained to the down-take from above. This forms a good mechanical finish. For convenience of inspectors there should be left projecting from the back wall of the down-take one or two brick headers about 2 inches projection. One should be placed opposite the middle half of the flue tube and one or two at a lower position for foot rests in descending to the bottom flue. It is now considered best practice not to build the covering bricks over the side flue cover close up to the boiler, but to leave a narrow trough to enable the shell plate to be got at for inspection, this trough being filled with loose material, easily moved for inspection. Then the shell of a boiler is open to inspection all over, and if not arched over on the crown, this is covered with some compound which is at once loosened and softened by any leakage of steam, which is thus at once rendered visible. The inability to see the boiler crown is the real objection to the arching over of the flues. But if this arching is adopted, it should stop at least 4 inches clear of all mounting blocks. It was because of being closely bound in by the over-arching that a very serious triple explosion occurred some years ago. All the evidence pointed to the probability of the boiler having been hung by the manhole mouthpiece upon the over-arching, the seating below having settled and thrown the weight of the boiler upon this mouthpiece. In our illustrations, figs. 19, 20, 21 and 22, the various points touched upon may be studied. It should be added that the front wall of the seating must be placed behind and clear of the angle ring of the front end plate. This plate thus stands about 7 or 8 inches in front of the wall. This wall is usually 9 inches thick, and where it makes contact with the boiler, it should be reduced at least to half a brick. Indeed, there ought to be special narrow edged bricks moulded for this purpose. Below the boiler this front wall must be recessed and taken behind the blow-out block. When the blow-out pipe comes through the front wall, as once common, it often broke off when foundation settlement let the full weight of the boiler upon this one pipe. A space of 4 feet is left between the ends of the seating walls and the front wall to admit the gases to the side flues. The hearth pit is made at least 6 inches, preferably 12 inches, and often 15 inches deeper than the bottom flue; this prevents danger of water in the flue from the hearth pit. The openings to the flues are best made through the front wall in the hearth pit at each side of the blow-out recess. These openings may be 18 inches square where the bottom flue is not less than 30 inches deep. They consist of a cast-iron frame and a close-fitting door hung on lugs. The frame must be flush with the flue bottom to allow dust to be brushed out easily. The hearth pit often measures 39 inches in width between walls, and should be a continuous trough along the front of a set of boilers. Nothing should be allowed in the hearth pit except the blow-out tap and pipe. It is bad practice to allow feed pipes to be laid along the pit. It is usual to lay the waste pipe into which the various blow-outs discharge along the pits. It is a very undesirable practice to have a waste pipe common to two or more boilers owing to the danger of blowing back into an empty boiler of steam and water from a boiler that is blowing off.

The safeguard of a single key, which can only be removed from the blow-out tap when this is closed, is theoretically infallible, but it is easy to suppose the key lost, a new one obtained, and the old one found, when there would be two keys, and perhaps everyone would not know of it. Therefore, avoid a common waste pipe, carry all blow-out wastes, if possible, to their own independent discharge. Failing that, it is possible that a waste pit with freely open standpipe to the air might be permitted. If a common waste pipe must be used, it should increase in size as it passes along the line of boilers. It should be single-ended only, and each boiler branch should point in the direction of flow, so as to induce a current to the discharge end, which should be protected from frost.

Hearth pits are usually covered by plates of cast or wrought-iron set in a frame. Each plate should be not over a foot in width, and it should not exceed $\frac{7}{16}$ths in thickness, with a stiffening rib. Each plate should be edge planed, and have chipping bits at each corner to fit them free from rocking movement in their places on the framing. It should have a slot at each end for a ⊥ key, and should be free from twist and an easy fit in the frame when the boiler is under full steam. The middle plate requires a small circular hole, with cupped cover plate, to take the blow-off key, and this middle plate ought to be lifted for an inspection of the hearth pit every day. This centre plate is supported by a flange along the

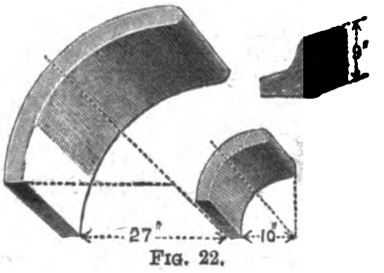

Fig. 22.

under side of each adjoining plate. It is considered permissible to take the waste pipes from the glass water gauges into the hearth pits, because otherwise the blowing out of the gauges is a nuisance, but this practice is rather apt to cause mild corrosion of the shell plate round the blow-out block. If a through draught can be secured from end to end of the hearth pits this should be done. Sometimes hearth pits are uncovered, being merely protected by a kerb of stone. This is good practice, in the writer's opinion, if the stokers will keep the pits clear of ash and coal. A portable plate or two may then be employed to carry the ash barrow when cleaning fires, and each blow-out tap should have a covering cap. By means of a set of rails an ash trolley may be run along the front of all the boilers for this purpose. The bottom of hearth pits, whether these be open or otherwise, should be smooth cemented, and sloped to the middle of the pit and one end to promote drainage. The advantage of the open hearth pit is this: Where cover plates are employed these must be fully 1 inch clear of the

Digitized by Google

lower edge of the front end plate, or there is liable to be an accumulation of damp ashes about the angle iron ring. Serious corrosion has been thus caused. The open pit can conveniently be arranged with boilers of 7 feet diameter. But with boilers of 8 feet, and the large angle rings demanded by modern pressures, the grate surface is raised so high above the firing floor as to reduce the efficiency of the fireman.

With open hearth pits the front end plate may project below the level of the floor with safety. Where cover plates are retained, the bearer along the boiler front wall should have a back flange at least 4 inches high, and rising at the middle to fit round the boiler shell. This fender flange is to prevent the fall of ashes into the hearth pit, and generally to give a finish. It is customary to keep this plate bright in well kept boiler houses. Over the whole of the brickwork above the side flues one of the neatest ways of finishing the work is to lay thin, smooth flags of York stone, with rounded edges, where they overlap the brickwork. The best system of damper is that which provides a narrow damper to each side flue. These side flue dampers slide in a light frame of cast-iron built into the walls of the flue, which is here widened out to 12 inches. The damper opening is 12 inches, and the damper itself, if carefully fitted, need not exceed 13½ inches in a well-made frame. If circumstances permit, the narrowest part of the side flues may be greater than 9 inches, but should not usually exceed 12 inches. Each damper should be balanced by a weight hung by a chain over a pulley, carried on a pillar or frame suitably supported. On the axis of the pulley should be fixed a light wheel of 20 inches diameter carrying a flexible steel cord ⅜ths inch diameter. This cord is brought to a convenient spot on the firing floor—preferably down the pillar or pier of the large doors usually found closing the front of the boiler house. By this cord the dampers can be raised or lowered. It may either be a continuous cord or, if single, the balance of the damper must be imperfect, so that the damper will move in one direction by gravity. Obviously the damper gear must be liberally proportioned, and finished in a mechanical manner.

It is to be regretted that in items forming the substance of this chapter the fitting and finish of boilers and boiler houses which have been carried out by electrical contractors are often deplorably behind the best recognised practice.

A distinctly retrograde movement has been made as compared with the recognised standard of the leading boiler insurance companies. Much of what these articles contains is, in a sense, ancient history, and would not have been set down had it not appeared that there was a distinct need for it. An inspection of almost any modern factory in Lancashire, or even in Yorkshire, will show a practice differing but little from what has been here set down.

In actually setting a boiler, it is usual to first build up the brickwork as far as the level of the side flues. The boiler is then supported over its seating upon two sets of timber blockings laid in the bottom flue. It is set with a slope of $\frac{1}{16}$th of an inch to the foot of length towards the front end to facilitate blow-out and washing. The seating blocks are then put in position and firmly wedged in place to carry the weight of the boiler, fireclay only being employed as mortar. The boiler is then allowed to bear on the side walls by removing the temporary supports, an operation, perhaps, best effected by a screw jack, but sometimes by breaking up the old bricks which have formed one layer of the temporary supports. In designing a boiler seating, plain straight line work should be used as far as possible.

(To be continued.)

OVER-COMPOUNDING DYNAMOS.

By E. K. SCOTT.

In over compound wound dynamos it is necessary to increase the magnetism at a rate roughly proportional to the load needing the over-compounding. It is important, therefore, to work between such points on the magnetisation curve that the useful lines of force are somewhere proportional to magnetising force, or, in other words, that part of the B H curve which is immediately below the corner leading to saturation, say, x y, fig. 1. Working at a low point in the curve

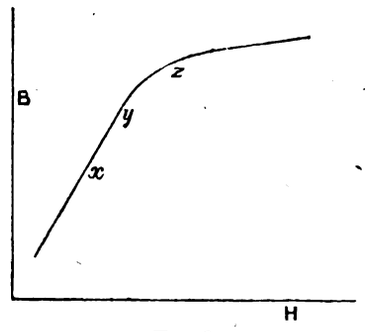

Fig. 1.

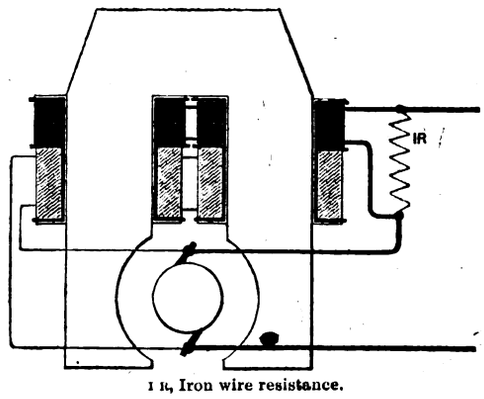
naturally means a reduced output per unit weight of material, and various propositions have been made to enable the machine to work at a higher induction density and still give the same over-compounding result. Fig. 2 shows one method



I R, Iron wire resistance.

Fig. 2.

which has the advantage that it is automatic. An iron wire resistance is put in shunt with the compound coils, and its section is so proportioned that increase of load, combined with the high temperature coefficient of the iron, shunts more and more current through the series coils, thus compensating for the diminishing permeability of the magnetic circuit at the part of the curve, y z. The coils themselves, and the losses in them, of course cost money, but the increase in output for a given sized carcase more than covers this.

It will readily be seen that a similar arrangement can be used in which the regulation is by hand, as in fig. 3, and

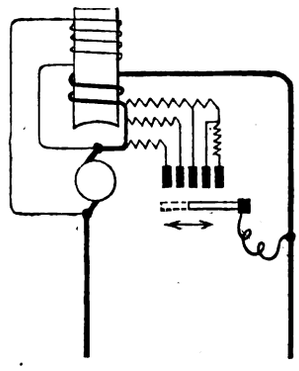


Fig. 3.

this latter method has the advantage that the band of the voltage curve can be compensated for.

An interesting fact, observable especially on traction machines where the load varies greatly, is that over-compounding tends of itself towards sparkless commutation; for the increase of magnetisation corresponding to the increase of voltage from 520 to 580 volts gives just the necessary strength of field for commutation without shifting the

Digitized by Google

brushes. In other words, it is a distinct gain to over-compound a machine even when such over-compounding is not absolutely necessary from the point of view of getting a steady voltage at some distant point. Seeing that over-compounding means very little extra complication, it would appear that it might, with advantage, be applied to ordinary central station lighting dynamos, which are at present always wound shunt.

Some specifications for lighting dynamos have recently been issued, in which the ordinary shunt-wound machines to give 460 volts were asked for, but there was also the proviso that if at any time electric traction should be decided on, the dynamos should be able to give the voltage required for this work by the simple addition of series turns on the field coils.

Now, with 220-volt lamps, the voltage of the dynamo is generally fixed at 460 volts, whilst for the ordinary 500-volt traction motor the pressure at the generators may be anything between 520 and 580 volts. Say the highest voltage required is only 560, then it means that the mere addition of series turns to the dynamo has to add 100 volts, or 22 per cent. Such a thing might possibly be done, but what about the expense? As pointed out above, the only way to make provision for increase of voltage is to work low down on the magnetisation curve. To utilise lighting dynamos in the way suggested, therefore, means that when running on lights the fields will be very weak, and this, as everyone knows, is an invitation to sparking troubles at the commutator. As the machine must necessarily be of low efficiency and expensive, the game hardly seems worth the candle; besides, it is more than probable that when the traction scheme does come along, the idea of using the lighting machines for the purpose will have been abandoned. Using a higher voltage lamp than 220 would help to get over the difficulty, but the writer thinks that this idea of working lamps and a traction load from the same machines should be dropped. It looks pretty on paper, but it doesn't pan out quite right in practice.

REDUCED RATES TO INDIA.

We are glad to reproduce the following:—

Upper India Chamber of Commerce,
Cawnpore, *August 15th*, 1899.

The Under-Secretary to Government,
North-Western Provinces and Oudh,
Public Works Department,
Naini Tal.

Sir,

Reduction in Telegraph Rates between India and Great Britain.

In connection with the correspondence ending with your letter, No. $\frac{1343}{125}$M., dated Naini Tal, June 9th, 1899, advising that the Government of India "had addressed the Secretary of State with a view to securing a reduction of not less than 50 per cent. in the present tariff, at as early a date as may be practicable," I am directed to express the hope that His Honour the Lieutenant-Governor will support this further representation on the subject, as the facts which have been recently made public in England, regarding the working of the Anglo-Indian telegraphs, appear to accentuate the practicability of the views held by the Upper India Chamber of Commerce, viz., that a shilling per word rate would largely increase traffic and yield a fair profit on the working of the system.

In the course of an interview granted by the Chancellor of the Exchequer to a deputation of members of Parliament on July 12th, 1899, Sir Edward Sassoon stated that "A new telegraphic line had been sketched out by the Indian Government, which would supersede the existing Eastern Company's route to the East, and would give them cheaper rates and a safer line." The Chancellor of the Exchequer is also reported to have said that he was disposed, so far as his personal opinion was concerned, entirely to admit that; at any rate, with regard to India, there was a very considerable grievance in the cost of telegraphic communication, and that some such system as that suggested by Sir Edward Sassoon would do a good deal to improve the position in this matter.

Again, from the evidence given by representatives of the Eastern and Eastern Extension Telegraph Companies before the Pacific Cable Committee, it would appear that in the case of telegrams to Australia sent *viâ* India, only 1s. 4½d. per word is received by those lines which transmit the message from London to Bombay, the balance of the total charge of 4s. 9d. per word being allotted to the lines on the route further south. In other words, the Indian public is paying 2s. 7½d. more per word for the transmission of its messages to London, than is paid by the Australasian community for the transit of their messages from India to London, exactly the same distance, over exactly the same route.

The Marquis of Tweeddale, as chairman of the Eastern Telegraph Company, in communications addressed to the Press in defence of the company, states that: "With respect to India, the Eastern Company has already intimated to the Chambers of Commerce that it is prepared to negotiate for a reduction in the Indian rate, and has good reason to believe that negotiations with that object will soon be commenced between the India Office and the company." He further adds:—"As for the press rates, they are nominally less than the commercial tariff, no coding is permitted, and 'expansion' is inconsiderable, so that the present charges, it is admitted, bear more heavily than they might perhaps do on the purveyors of news." And he then goes on to say, "Supposing reductions of rates should, however, lead to a great increase of business, our cables would not be sufficient, and we should have to spend money in providing others."

The vice-chairman of the Eastern Telegraph Company, in a letter dated June 8th, 1899, addressed to the chairman of the Glasgow Chamber of Commerce (copy enclosed) clearly indicates, however, that if a reduction in tariff rates be made, the company will look to the Indian Government to bear a share of any *loss of revenue* which may be thereby caused; and in the memorandum accompanying the letter it is stated that experience has shown the traffic between India and Europe to be a non-expansive one. Further, that the company have not received a single application for reduction of rates from merchants, who are the actual users of the telegraph, ignoring the fact that the said merchants and others have for years been in communication with the Home and Indian Governments on the subject, through their representatives, the various Chambers of Commerce in England and India. Again, the allegation in the said memorandum, that the Indo-European traffic is non-expansive, hardly coincides with the chairman's views as to the possibility of a reduction in rates bringing about a large increase of business, necessitating the laying down of additional cables by the company.

But as it pays those interested to convey messages from London for Australia, as far as Bombay, for 1s. 4½d. per word, it would presumably be a fair speculation to either duplicate the existing system, or to provide another route, if need be.

My committee hold that the reduction in tariff rates to 4s. per word in 1896 still left the charge at too high a level to induce any considerable expansion in traffic, but that, as originally advanced by this Chamber, 1s. per word rate, while constituting a great convenience to trade, the general public, and the Press, would yield to an independent line a volume of traffic sufficient to allow of the system being worked at a substantial profit. I am, therefore, directed to express the hope that, when forwarding this letter to the Government of India, his Honour the Lieutenant-Governor of the North-Western Provinces, and Chief Commissioner of Oudh, may be able to countenance and support the opinion of this Chamber as to the feasibility of 1s. per word rate between Great Britain and India, with a maximum charge of 2s. per word for the privilege of priority of despatch over other messages, so as to meet the cases cited by the vice-chairman of the Eastern Telegraph Company, "Limited," in paragraph 2 of the memorandum attached to the communication addressed by him to the Glasgow Chamber of Commerce.

I have the honour to be, Sir,
Your most obedient servant,
W. B. Wishart, *Secretary*.

Reduction of Telegraph Rates between India and Europe.

The case for the Companies.

The following letter and memorandum have been received by Mr. John Galloway, chairman of the Glasgow Chamber of Commerce, with regard to the movement in favour of the reduction of the rates charged for telegraphing to India and the East:—

Eastern Telegraph Company, Limited,
Winchester House, Old Broad Street,
London, *June 8th*, 1899.

Sir,—Referring to our interview of the 1st inst., I now enclose copy of a memorandum which has been prepared with regard to the Indian tariffs. This memorandum can be freely used, and it has been submitted to our partners, the Indo-European Telegraph Company.

I can only repeat that these companies are willing to consider any offer which may be made to them by the Indian Government for a reduction of tariffs, and are equally prepared to bear a share of any loss of revenue which may be caused by the reduction required.

Yours faithfully,
J. Denison-Pender, *Vice-Chairman*.

Memorandum.

From some years past the company carrying the traffic between Europe and India have been memorialised to reduce the Indian rate. The companies have always expressed their willingness to reduce tariffs whenever experience has shown that a natural expansion of traffic has taken place, and is likely to take place by a reduction of tariffs, and have also always been and are now willing to take a fair share in any reduction of tariff, if the Governments concerned would bear a proportion of the actual loss of revenue, the companies not only bearing a share of the loss, but undertaking the extra expense of carrying any increased traffic. The reasons which have influenced the companies with regard to the Indian tariff have been as follows:—

1. The traffic between India and Europe has been shown by experience to be a non-expansive one, and the companies consider that it would require a very large reduction of tariffs to materially increase the actual traffic carried. The following figures will speak for themselves. The tariff was reduced to 4s. per word on July 1st, 1896:—

Digitized by Google

	Words.	Revenue.* £		Words.	Revenue.* £
1885 ...	2,158.521	394,270	1892 ...	2,300,823	364,196
1886 ...	2,153,507	374,121	1893 ...	2,367,353	376,237
1887 ...	2,134,002	342,271	1894 ...	2,190,102	347,728
1888 ...	2,110,163	334,129	1895 ...	2,195,916	358,724
1889 ...	2,029,149	328,490	1896 ...	2,180,158	353,683

1891 ...	2,250,074	354,749	1898 ...	2,275,371	366,019

* Revenue of administrations owning the telegraph lines between India and Europe.

2. In all the correspondence which the companies have had with the merchants who are the actual users of the telegraph, we have never had a single application for a reduction of tariffs, but we have had applications to be allowed to send at a higher rate, in order that one person's telegrams might have the preference over those of others.

3. The perfection, to which the system of coding telegrams has been brought, practically reduces the charge of 4s. per word to India to about 2d. per actual word sent by the merchant, a figure that cannot be called dear.

4. If the traffic were to increase through a reduction of rate so as to recoup the companies for the total loss made, it would necessitate the laying of extra cables between Great Britain and India, a single line of which could not be laid under a million and-a-half of money, and if this large increase took place, the companies would have to face this additional expenditure of capital, with the consequent annual charges for interest, maintenance and working.

A HAPPY DESPATCH!

How many readers of the Electrical Review have any knowledge of the long-forgotten Pneumatic Despatch Company's railway between the G.P.O, St. Martin's-le-Grand, and Euston Station? It ceased working in the year 1869 or '70, and the first engineering experiences of the writer were gained on that line, abandoned for 20 years, and now about to be again operated by electric traction in place of air pressure and vacuum. A very exhaustive and interesting report on the inception and history of the ill-starred Pneumatic Despatch has just been made by an engineer, Mr. George Threlfall, a copy of which he has kindly placed at our disposal.

In 1895 it came to his knowledge that there was a tube running underground in London, having been built by a company about 39 years back for the purpose of conveying mails, parcels, &c., by pneumatic despatch.

It occurred to him that if the tube was still available it might be possible to utilise it for its old purposes, if worked by electric traction, but the tube had been closed for so many years that all the plans and records of it seem to have been lost, and it took practically three years to collect sufficient information and plans to enable Mr. Threlfall to draft out a feasible if not a perfect scheme.

The tube runs from the G.P.O., up Newgate Street and Holborn to Tottenham Court Road, up the Tottenham Court Road and the Hampstead Road, turning down Drummond Street and Seymour Street, and then turning up to the Northern District post office on Eversholt Street. It is of cast-iron, 4 feet high, and 4 feet 6 inches wide, and about ¾ inch thick.

Mr. Threlfall found it to be nominally the property of a company called the Pneumatic Despatch Company, founded in 1859, but which had lost its rights by efflaxion of time. He hunted up the prospectus and history of the old company, and found that it had been a very powerful one, having been granted special rights by Acts of Parliament enabling it to open up the streets, and do all that was necessary to lay down and keep in repair its tubes for the purpose of despatch in any part of London.

Its board of directors consisted of the Marquis of Chandos, Mark Hulse, Esq., Thomas Brassey, Esq., Edwin Clarke, Esq, John Horatio Lloyd, Esq., Hon. Wm. Napier, Sir Charles J. H. Rich, Bart., W. H. Smith, Esq., with T. W. Rammell, Esq., and J. Latimer Clark, Esq., engineers; John Aird, Esq., contractor; and Baxter, Rose, Norton and Spofforth, solicitors.

He saw all the surviving members of this board with the view of inducing them to aid him in resuscitating the company, and working their tube by electric traction instead of pneumatic despatch, and practically all the old stockholders of the company were interviewed, proxies procured from all, and affidavits from some. After endless delays and disappointments, Mr. Justice Vaughan Williams, in the High Court of Chancery, resuscitated the Pneumatic Despatch Company, with all its original powers, on June 6th, 1896, and an agreement between the Old Pneumatic Company and the New Syndicate (the London Despatch Company) was duly signed in May, 1899.

Mr. Threlfall having satisfied himself that the tube was suitable for electric traction, and that he could obtain possession of it on reasonable terms, he approached the Postmaster-General with a view to finding out the views of the G.P.O. as regards the utilisation of it if re-equipped with electric power. He saw the Secretary, Mr. Preece (chief engineer and electrician of the G.P.O.), and subsequently Mr. Fleetwood (his assistant), who really administers the despatch and electrical departments, and found that although they could not commit the Treasury by making positive statements, they personally were quite ready to entertain the matter, and give it their very careful consideration and qualified support, and there is little doubt but that the Postal Department will utilise the tube when electrically equipped, particularly as the requirements of the G.P.O. have increased enormously since it was laid down on the pneumatic system. One of the chief difficulties the G.P.O. experiences at present is to get prompt delivery of the mails to the different stations in contract time (8 miles per hour), owing to fogs, slippery pavements, congestion of traffic, &c., and there are no parts of London where they suffer more from these causes than in those under which the tube passes.

Since the date of the construction of the old tube, the G.P.O. have built a new Western District office in Holborn, on the route of the tube, and there is a large traffic, both in mails and parcels to and from that office. The Euston traffic is extremely heavy; in fact, the postal authorities state that it is heavier than any of the other station mails, the heaviest hour of the day amounting to 11 tons of mails. That to the Northern District Post Office, Eversholt Street, is also very heavy. They therefore look upon a scheme that will give them, in the first place, quicker service (say, 25 to 35 miles an hour), and one that will not be subject to street traffic obstructions and conditions, with great favour, and although they will not enter into a hard and fast contract until they have plans, particulars of delivery, speeds, &c., put before them, and guarantees offered, there is little doubt but that they mean business, as they have not only given Mr. Threlfall every assistance up to the present, but have offered to do everything in their power to facilitate the re-equipment of the tube.

When first the old company was reinstated, Mr. Threlfall began to consider the best way of re-equipping the tube without raising too much cash capital. He therefore approached some friends, building and railway contractors of first-class repute, with a view to their undertaking to repair and put the tube in order. He also requested a large firm of electrical engineers to undertake the electrical equipment; and he approached Prof. Carus-Wilson for the purpose of his preparing the plans and specifications for the equipment of the tube electrically. After having thoroughly explained the matter to these firms and gentlemen, and having taken their representatives into the tube, they each undertook to contract for the work required, and instead of asking for cash for the work done, undertook to accept payment in debentures of the new company.

The acceptation of the work by each of them on the lines of payment in debentures and shares gives, Mr. Threlfall thinks, the greatest proof possible of what practical men think of the prospects of the proposed company, which will not give them one penny for their work unless the scheme is a success.

During the time the old company was non-existent, the tube was practically no man's property, and the St. Pancras Vestry could not be blamed for taking advantage of it for the purpose of running their electric wires, but we understand they have now fully recognised the ownership of the Tube Company.

Regarding this, the most important vestry along the route, and the only one which is trespassing in the tube, Mr. Threlfall has approached them, offering to give every assistance in his power to enable them to remove their wires in the most convenient manner, and at the same time he has proposed to take from them some of the electric current which will be required in place of building a separate electric station for the generation of electricity.

In Buda-Pesth a line on exactly this principle is at the present time being laid down for identically the same purpose of carrying mails and parcels. At the same time wishing to get reliable and unbiassed opinions on the subject, Mr. Threlfall approached several of the chief authorities, and they all approve of it.

Satisfactory arrangements for financing this undertaking have, we are informed, been made, and a company bearing the name of the "London Despatch Company, Limited," was registered on May 19th, 1899, with its offices at No. 50, Fenchurch Street, London, E.C., with a share capital of £10,000 made up of £10,000 shares of £1 each, and the power to issue debentures up to the same amount.

The idea of forming a small company at the first, instead of a larger one, has been adopted more with a view to allocating the different interests acquired during the last five years in a parent company, and also with a view to the small company finally settling with all vestries, clearing and repairing the tube, drafting out the electrical equipment, equipping one section for Post Office and other experiments, and finally procuring the Post Office contract and bringing out a larger company. For this purpose it is considered the money subscribed, namely, £5,000 cash on debentures already subscribed, having the right to raise a further £5,000 cash on the remaining debentures, is ample.

The steps which the directorate now intend to take are, first, to obtain a recognition of their powers from the various vestries through which the tube passes, and then an undertaking from three of the vestries at least to supply the company at a reasonable rate with the electric current which may be required.

Prof. Carus-Wilson is now drafting out the actual requirements of the company from the electrical point of view, and probably the piece of tube between Euston and Eversholt Street Post Office will at once be equipped for experimental purposes, and the experiments will be carried on under the personal guidance of Prof. Wilson.

While the Professor's experiments are proceeding, an entrance will be obtained to the tube at sundry points, and the tube will be repaired where necessary, and the railroad put in thorough order for running cars.

The minutest details will be obtained of the General Post Office authorities' requirements, so that a full report and scheme may be put before the Postmaster-General with a view to procuring a firm contract from him. The requirements of all the railway companies having receiving offices on the route, of the general carriers and delivery companies, &c., will be carefully studied, and provisional contracts entered into with them where possible.

Having completed all these different details, and having obtained the General Post Office contract, and any other contracts from railway companies or carriers, the parent company will bring out its larger company, and finally equip the tube to its full working capacity.

Digitized by Google

The writer, who was closely associated with the final struggle of the Pneumatic Despatch Company, when after six months of regular daily work the scheme was abandoned and passed into oblivion, has often wondered why that which has now come to pass, was not undertaken at an earlier date; but it has been left to Mr. G. Threlfall, the managing director of the new company, to make what we hope will prove a success of an underground railway, which, started at a time when the commercial application of electric traction was unknown, was bound to come to grief, for reasons which we need not stop to discuss, with air propulsion as its *modus operandi*.

Mr. Threlfall is to be congratulated on the energy and perseverance with which he has carried on his self-imposed task during the past four years, and it will not be his fault if the tube now under consideration is not in early operation, and extensions in hand.

On the 11th inst. the *Daily Mail* published a sensational, and technically inaccurate, account of "London's Lost Tunnel." The engines were never increased from 100 to 800 H P. Fancy 800 H P. to drive two or three trucks through the Pneumatic Despatch Company's tube! No wonder the financial results were on the wrong side.

The figures relating to the number of trolleys and weight to be carried are also wholly misleading.

Each electric locomotive is calculated to draw as a maximum, *seven* trolleys, each taking *one* ton, in addition to the weight of the trolley, at a maximum rate of 40 miles an hour.

AMERICAN TELEPHONE PRACTICE.*

Self-induction and Capacity.

By KEMPSTER B. MILLER.

Every insulated conductor is capable of receiving a certain charge when subjected to an electromotive force; for instance, if a metallic plate insulated from all surrounding bodies is connected to one terminal of a battery the other terminal of which is grounded, a certain amount of electricity will flow into the plate until its potential is raised to that of the battery terminal. The plate is then said to be charged, and the amount of electricity held by it determines its capacity. The charge of electricity on the plate will be considered positive or negative, according to whether the positive or negative terminal of the battery, or other charging source, was connected with it.

It is well known that no charge exists by itself—there is always an equal and opposite charge induced by it upon neighbouring bodies. It is also well known that like charges repel each other, while unlike charges attract; that if an uncharged body be brought near a charged body an equal and opposite charge will be induced on the side of the uncharged body which is toward the charged body, and that similarly a charge of the same sign as that on the charged body will be induced on the opposite side of the uncharged body. If now the body which was originally uncharged is connected with the ground, this latter charge, that is, the one of the same sign as the original charge, will be driven to the ground, while the charge of opposite sign will still be attracted by the charge on the first body. The second body will therefore be charged, although it has not been in contact with the first. The action between charges of electricity taking place through an insulating medium is called electrostatic induction. It is found that where two conductors are placed side by side, but insulated from each other, the capacity of each will be greater than if the other were not present. For the purpose of holding charges in this manner the well-known Leyden jars have long been in use. They are usually made by coating a glass jar inside and out with a layer of tin-foil to within a few inches of the top. The outer coating is usually connected with the ground, while the inner coating is connected with a metallic rod approaching it through the mouth of the jar. If the inner coating is connected with a source of electromotive force, a current lasting but an instant will flow into the coating, producing a charge. This charge, which we will say is positive, will attract a nearly equal negative charge to the outer coating, repelling an equal positive charge to the earth, as already described. The amount of charge which the inner coating will receive under these circumstances is very much greater than if the outer coating were not present, and the capacity of the inner coating is therefore much higher than before. A device, such as the Leyden jar, is called a condenser.

The capacity of a condenser is increased as the area of the conducting surface is increased; is increased as the distance between the conductors is diminished, and may be increased or diminished by using different kinds of insulating material between the conductors. The medium separating the conductors is called the dielectric and, as stated above, upon it depends to the greater extent the efficiency of a condenser. Several condensers built exactly alike so far as size of plates and the distance between them is concerned, and using different materials for dielectrics, will be found to have different capacities. This difference is due to a peculiar property possessed to different degrees by different dielectrics and called specific inductive capacity.

The specific inductive capacity of a dielectric is a measure of that quality which enables the dielectric to hold a charge between two conductors, as in a condenser. The specific inductive capacity of air is taken as a standard and is for convenience considered as unity; it is lower than that of any other known substance excepting, perhaps, hydrogen. If two condensers having plates of equal size and distance apart are constructed with dielectrics respectively of air and gutta-percha, it will be found that the condenser having the dielectric of gutta-percha will receive a charge nearly 2½ times as great as the condenser having the dielectric of air. The actual ratio between the two is 2·462, and for this reason the specific inductive capacity of gutta-percha is said to be 2·462. The following table gives the specific inductive capacities of some of the more important insulators:—

Air	1·00	Ebonite	2·284
Glass	3·013	India-rubber	2·220
Shellac	2·74	Paraffin	1·994
Sulphur	2·580	Carbonic acid	1·00036
Gutta-percha	2·462	Hydrogen	0·99967

It is probable that with very rapidly varying electromotive forces, such as are dealt with in telephones, the specific inductive capacities of the various substances would be higher in comparison with air than those indicated by this table.

Specific inductive capacity is a very important consideration in the construction of cables for telephonic purposes. In the construction of these cables it is desirable, as will be shown later, to reduce the capacity of the wires of the cable to as great an extent as possible, and in order to do this the dielectric is, in the best forms of cables, made of dry air to as great an extent as possible. On the other hand, in the construction of condensers it is desired that the capacity may be as great as possible for a given area of plates, and therefore some material other than air is used. Paper saturated with paraffin is perhaps the most commonly used, paraffin having about twice as great a specific inductive capacity as air, and, moreover, lending itself readily to the purposes of insulation. To sum up, the capacity of a condenser varies in direct proportion as the area of its plates, inversely as the square of the distance between the plates, and directly as the specific inductive capacity of the dielectric.

The effect of a condenser bridged across a circuit carrying an alternating current is to absorb a portion of the current as the electromotive force at its terminals increases, and as the electromotive force decreases, to give this current back to the line. Consider such a circuit when the electromotive force active in driving current through it begins to rise. The electromotive force at the condenser terminals will also rise, and current will therefore flow into the condenser. The strength of this current will depend directly upon the rate at which the potential at the terminals of the condenser is changing. When the electromotive force acting in the circuit reaches a maximum, the potential at the condenser terminals will also be a maximum, and will for an instant cease to change. At this point the condenser is fully charged, but as the electromotive force of the line is not changing, no more current flows into the condenser. In other words, the condenser current is zero. As the electromotive force in the line decreases, current will flow out of the condenser and into the line, because the condenser is not

* *American Electrician.*

Digitized by Google

capable of holding so much charge at the lower potential. The flow of current out of the condenser reaches a maximum when the electromotive force in the line is changing most rapidly, and this occurs when it is passing through zero. From this it will be seen that the condenser current is zero when the electromotive force in the line is a maximum, and is a maximum when the electromotive force in the line is zero. This indicates, as in the case of self-induction, a phase difference of 90°, or a quarter of a cycle. It is not so easy to say whether this phase difference is lagging or leading, but a consideration of the direction of flow of current throughout the cycle will throw some light upon the subject.

At the instant when the current flowing in the line (which is in exact phase with the active electromotive force in the line*) is positive and at a maximum, the condenser current will be zero. As the active electromotive force decreases toward zero, the condenser current increases, but in a different direction—negative—because current is now flowing out of the condenser back to the line. As the active electromotive force reaches zero, the condenser current is at its maximum negative value, and as the active electromotive force reaches its maximum negative value, the condenser current reaches zero. During the next half cycle the condenser current increases to a positive maximum, and decreases to zero, while the active electromotive force passes from a negative maximum to a positive maximum. In other words, while the active electromotive force and therefore the line current with which it is in phase decrease from a positive maximum value to a negative maximum value the condenser current is negative, and while the active electromotive force increases from its negative to its positive maximum value the condenser current is positive. The condenser current, therefore, reaches its zero value, while decreasing, 90° in advance of the same value of the active electromotive force; its maximum negative value, 90° in advance of the maximum negative value of the active electromotive force; and upon investigation it will be found that every value of the condenser current occurs 90° in advance of the corresponding value of the actual line current. The electromotive force which is in phase with the condenser current is called the condenser electromotive force, and is 90° in advance of the electromotive force which is active in driving current through the line. This latter electromotive force, which, as we have said, is in phase with the current flowing in the line, is the resultant of the impressed electromotive force, and the condenser electromotive force, and therefore leads the impressed electromotive force by a certain angular distance.

The current equation for a circuit containing resistance and capacity is, as before,

$$\text{Current} = \frac{\text{Electromotive force}}{\text{Impedance}}.$$

In this case the impedance depends on the ohmic resistance of the circuit and on its capacity, and is equal to the following expression:—

$$\sqrt{R + \frac{1}{4\pi^2 f^2 c^2}}.$$

Where f is the frequency, as before, R the ohmic resistance, and c the capacity of the condenser in farads. From this the current equation becomes

$$C = \frac{E}{\sqrt{R^2 + \frac{1}{4\pi^2 f^2 c^2}}}.$$

The denominator is the apparent resistance, depending upon the ohmic resistance of the circuit, the capacity and the frequency of alternations. An inspection of this equation will show that as the frequency, f, is increased the impedance or apparent resistance becomes smaller, and this accounts for the fact that a condenser will readily transmit rapidly fluctuating currents, such as voice currents. Evidently the effect of increasing f reduces the second member in the denominator of the equation, and if sufficiently great, this may be neglected, and the equation becomes simply

$$C = \frac{E}{R}.$$

Again, increasing the capacity of the condenser also increases the effective current by reducing the impedance.

Every telephone line possesses electrostatic capacity, and may be considered in the light of a condenser. In the case of a grounded circuit, the line wire takes the part of one plate of the condenser, while the ground and other neighbouring conductors act as the other plate. In metallic circuits the one side of the line acts by electrostatic induction upon the other, and the two together, upon the ground and neighbouring conductors. The capacity of a line, however, differs from that of a condenser in that it is distributed throughout the entire length of a line, while a condenser connected with a line would have all of its capacity at a single point. Capacity, such as that of a line, is termed distributed capacity in order to distinguish it from that possessed by a condenser, which may be termed local capacity. The effect of distributed capacity upon telephone currents may be more readily grasped by imagining a large number of condensers bridged across the two sides of a metallic circuit at frequent intervals. When the electromotive force impressed upon one end of the line increases, a current flows from the source over the line wire and into the condensers, charging them all according to the difference of potential across their terminals.

The difference of potential across the terminals of all the condensers will not be the same, because there is a certain drop, due to the ohmic resistance of the line wire. If the current flows in that direction long enough to charge all of the condensers on the line, then a current will reach the distant end of the line, and if it continues in that direction, will attain its full value, in accordance with Ohm's law. It must be remembered, however, that each condenser is capable of taking a certain charge, and in order to receive this charge, a certain quantity of electricity must flow over the line wire.

The quantity of electricity which flows through a circuit depends upon the strength of the current, and upon the time it is allowed to flow. If the time is insufficient, it will be impossible for enough current to flow through the circuit to charge the condensers up to the potential of the source, and therefore the current at the distant end of the line will not reach its maximum value, and, in fact, may not rise practically above zero. If, therefore, the electromotive force of the source is reversed before sufficient current has time to pass through the line to charge all of the condensers, the current will not reach its full value at the distant end of the line.

It may begin to build up in the opposite direction, and again be stopped on account of the insufficient time to reach its proper value in that direction. The time in which the current in such a circuit will reach a definite portion of its maximum value at the distant end of the line is called the time constant, and if the time represented by one alternation of the electromotive force is smaller than the time constant, the current will not reach that value at the distant end of the circuit, and the transmission will be correspondingly impaired.

The reduction in the actual volume of current transmitted by the effects of distributed capacity is, however, of less importance than the distortion of the wave form. The higher frequencies of current waves corresponding to the higher over-tones are absorbed by the condensers far more readily than the lower frequencies, and, therefore, the waves corresponding to the higher over-tones are reduced to a much greater extent at the distant end of the line than those corresponding to the fundamental and the lower over-tones. This weeds out the upper harmonics, thus tending to destroy the clearness. Capacity, however, acts in still another way to alter the form of the wave. The angle of advance for the higher frequencies is greater than that for the lower, and, therefore, the waves of different frequencies are shifted with respect to their phase relation, thus greatly altering the wave form.

It has been shown that the electromotive force of self-induction lags 90° behind the active electromotive force, while the electromotive force due to capacity is 90° in advance of the active electromotive force. It is not difficult

* The active electromotive force is the resultant of the impressed electromotive force and the condenser electromotive force, and is in phase with the current actually flowing in the line

Digitized by Google

to conceive, therefore, that by properly proportioning the self-induction and capacity of a circuit the electromotive force of self-induction may be made to neutralise the electromotive force of capacity, and this result is readily obtained in experimental work.

In this case, even though self-induction and capacity may be present in a circuit to a large degree, the current flowing in the circuit is in exact phase with the impressed electromotive force, and its value is in strict accordance with the ordinary expression of Ohm's law. Unfortunately, however, for long-distance telephony such a balancing of self-induction against capacity can be obtained only for one particular frequency at a time. To thus tune a circuit for one particular frequency would render that circuit capable of transmitting efficiently one particular frequency of vibration, while the requirements of telephony are that all frequencies within the range of the human voice shall be transmitted with equal facility. Again, and unfortunately, it has been found impossible to neutralise distributed capacity with anything but distributed self-induction, and this has not yet been accomplished in practice.

As for trans-oceanic telephony, the high static capacity of the cable has so far proven an insurmountable obstacle. It is impossible to conceive a transmitter capable of forcing such rapid undulations through our present form of cables. Clearly then the solution lies in the betterment of cables, or the substitution of some other transmission medium, rather than the improvement of the instruments themselves.

There can be little doubt that trans-oceanic telephony will finally be accomplished, but the indications are that our knowledge at the present time is not sufficient to cope with the problem.

CORRESPONDENCE.

"Stresses in Steam Engine Shafts for Electric Traction."

Now that the writer of the article on the above has expressed the meaning which he intended to be conveyed by the paragraph to which I took exception, there is, of course, no serious disagreement between us.

It is mostly, as he says, one of terms. I did *not* mean by the "ordinary stress" that corresponding with the current for which the circuit breaker is adjusted. By "ordinary stress" I mean that corresponding with the rated normal full load as generally understood by the manufacturer.

There is no need for me to endeavour to substantiate the 1,000 per cent. rise of torque, as your contributor concedes my point when he says: "If there were no circuit-breaker the braking action might be enormous." Everything depends, as I stated before, on the time lag of the generator and on the machine circuit breakers, and it is just here where, I think, we differ slightly, he assuming that the latter protect the machine absolutely, which I am not so sure of.

Your contributor takes his stand on a possible excess of stress of 100 per cent. above the ordinary not being exceeded; but, even bearing in mind that his "ordinary" stress is taken at from 50 to 150 per cent. above my "normal," I still think he hardly makes a sufficient allowance.

The following suggestions may be offered in support of this view:—

1. On a road on which the service is infrequent, or the grades severe, the *station* load may frequently vary momentarily in regular work to the extent of 100 per cent. above the normal (my normal); and, at the moment of the overload, any one engine may easily get considerably over this due to inequality of division of the load. If the machine circuit breakers were adjusted exactly for this load (100 per cent. above the normal), there would be such frequent openings of the circuit breakers that the station engineers would, I anticipate, soon alter the adjustment. I believe that on the Waterloo and City Railway the machine cut-outs are adjusted for 800 amperes, which is getting on for 140 per cent. above the normal rated output.

2. There can, it seems to me, be a considerable rise of current in the generator, and consequent stress in the shaft (over and above this 140 per cent.) before the circuit breaker acts. Indeed, but for the time lag of the generator itself, I see no reason why there should not be sufficient to shear the shaft, even with the circuit breaker properly adjusted.

I find that, if we could imagine a sudden increase of current sufficient to shear the shaft, this shearing would be performed on a 5-inch shaft, running at 350 revolutions, and transmitting 200 H.P., in roughly ·0007 second; the length under shear being 6 inches. That is to say, in that extremely short interval of time the angle of twist of the fly-wheel would be sufficient to cause shear of the shaft.

I have also made a rough attempt to gauge the time taken by the plunger of an "I.T.E." circuit breaker, before it liberates the catch, and find this to be of the order of ·024 second.

Obviously, therefore, if the generator had *no* time lag the current would easily have had time to shear the shaft before the circuit breaker acted (assuming my figures correct).

Perhaps some of our station engineers may be able to contribute some idea, from actual experience, of the rate of increase of the current, through armature and series coils, when these are short-circuited under an E.M.F. of 500 volts, say, with a 200 KW. set.

With what is virtually a closed secondary of very low resistance (the unlaminated field) the "time constant," as calculated from the dimensions of the magnetic and electric circuits should be reduced several fold.

If Mr. Philip Dawson would give us some particulars as to the numerous accidents which have happened in the United States due to shafts shearing and to faulty circuit breakers, which the remarks in his book and in the lectures before the Institution of Mechanical Engineers (see ELECTRICAL REVIEW, No. 1,045, Vol. 41) suggest, it would probably be very instructive reading.

I must conclude this somewhat lengthy letter with an apology to your contributor for having so imperfectly replied to his questions.

The speed of the shaft he asks for was 350 revolutions.

A. M. Taylor.

September 13th, 1899.

ELECTRICITY AT CRIPPLE CREEK MINES.

The prevailing idea of a gold mine as something inaccessible, is rather dissipated by an article by J. Tonge in the *Engineering Magazine* on the Cripple Creek district. In that favoured locality the miner can proceed to work in an electric street car. Nowhere else in the world can the gold miner do this. Curiously, however, there are mining districts in effete old England where the coal miner, in all his picturesque many coloured rags, can proceed to his work in an electric street car. This will set him down practically at the very pit's mouth, down which he will be wound by an old fashioned beam engine. There, however, he ceases to emulate the Cripple Creek miner who is wound down electrically, keeps his mines dry by electrical pumps, and uses electric drills. However, both the new and the old world miner have to laugh at all London. Thanks to a County Council which is advised to reject the one practicable method of electric traction, we seem to have said farewell to our hopes of securing in London the facilities enjoyed by the Staffordshire miners.

Cripple Creek is a curious district. Little over 6 square miles in area of hills and valley, and situated over 9,500 feet above the sea, one town, Altman, being placed at an elevation of 10,300 feet, this small area contains upwards of 150 productive gold mines, 15 of which send out over 1,000 tons of ore per month. The gold production in 1891 was about £1,600,000. In 1894 it had risen to nearly £3,000,000, and up to this year's July dividends, the shareholders had aggregated £1,600,000 in joint stock mines alone. A remote mountain pasture in 1891, the district now has a population of 50,000. Steam railroads encircle the area, but do not enter it, and the way to the mines was difficult, or, at least, arduous. This led to the construction of the electric line starting from Cripple Creek town and meandering through the district to Victor. It is a line of curves and grades, climbing to a height of 10,514 feet, or 1,000 feet above its two termini. The round trip takes one hour at 12 miles an hour average. The line is driven by water-power at Lake Moraine, 11,300 feet on Pike's Peak, and electricity is transmitted nine miles to a central distributing station. It is shortly to be extended to Colorado Springs, a distance of 32 miles. The mines of the district being so elevated, the cost of water and fuel was very heavy, and coal was hauled from Canon City coalfield, 30 miles distant and 5,000 feet lower in elevation. As a rule the mines are either naturally dry or have been made so by levels at lower elevations, and local streams are few and small. Water has often cost as

Digitized by Google

much as fuel, and with the usually inefficient steam plant at a mine power was a very serious item. Obviously the district was eminently suitable for electric power distribution.

In July, 1888, the first electric mining hoist was put into work at Aspen, Colorado, and is still in operation. It was driven by a generator at Hunter Creek. This did other work also, and was of 60 H.P., and later was changed for 125 H.P.

Early in 1893 a 500-H.P. plant was established at Maroon Creek, Aspen. There are to-day at Aspen motors of over 700 H.P., all deriving current from water-driven generators. They have replaced the steam engine and have paved the way for the universal establishment of electric-power plants at the mines in Colorado. The beginning at Cripple Creek was made with the power plants of the Colorado Electric Power Company at Carson City, 30 miles from the creek, and that of the La Bella Mill Water and Power Company at Goldfield, within the district of Cripple Creek itself. In each case power is generated by steam plant, the first transmitting current 27 miles, the second carrying coal 27 miles and transmitting current from a comparatively local station. The former company has a capital of £100,000 and a power of 2,250 H.P. It has worked since 1898. Current is generated at 500, transformed to 20,000 volts, and transmitted by three bare No. 3 copper wires arranged in a triangle on 30-foot poles, one wire being at the top. A telephone circuit of two wires is carried on the same poles. Distribution is made at 500 volts from step-down stations on Gold Hill and Battle Mountain.

Customers for 1,200 H.P. are already on the books, consuming each from 75 to 150 H.P. for large consumers, and down to 5 H.P. for small consumers; a hoist of 15 H.P. will serve a depth of 450 feet; 30 H.P. will serve down to 800 feet, and 100 H.P. may be used for the greater depths. The company leases to a prospector a small hoist, and a small prospector can put all his capital into development. He can purchase as soon as he finds pay streak. The minimum rent of 5 H.P. is £10 per month, including hire and supply. This may seem heavy, but it could be done in London. We are informed by a recent owner of a small steam plant that for a power much less than would be afforded by 5 H.P. of electric motors, his steam power cost, directly and indirectly, at least £300 per annum, and we know of a large printing office in America where the use of motors to each machine saves seven-eighths the power used in similar electrically-driven offices where shafting is employed, and one large motor. Yet the rated motor power of the multiple motor office is double that of the single motor offices. This simply goes towards proving that it is what is not used that constitutes the economy to be sought in electric driving. The Colorado Company rents out in the way described £12,000 worth of machinery. The La Bella Company has a capacity of 3,000 H.P., or 2,250 electric and 750 in compressed air; has 10 miles of underground air mains from its station to various mines, some of them two miles distant, while electricity is transmitted five miles. The power station is thoroughly modern. Coal is dumped into bins direct from cars and mechanically fed to the fires. Ashes are mechanically removed. Condensing engines are used. Being 10,000 feet above the sea, cooling towers are used to save water, the first application of the cooling tower in the State. The vacuum cannot attain 20 inches, for the barometer only stands at 20 inches of mercury.

The triphase system of distribution is used at 6,400 volts directly generated, but at the mines there are step-down transformers to 110 and 440 volts for light and motors respectively. Only 2 per cent. is lost between the power house and a 300-H.P. motor one mile distant. Lights can be operated from the motor circuit without flicker or any indication of fluctuating load. The chief uses of electrical power are hoisting and air compressing for drills, the latter being the chief power consumer at most mines.

The saving effected is estimated at from 15 to 50 per cent., according to location and circumstances, irrespective of reduced wage account, of greater reliability and convenience, and freedom from stoppage by frost. The use of electricity has thus rendered possible the use of lower grade ore, hitherto not available, this being unprofitable at the high rates for power. We commend this brief history of electrical power distribution to the hesitating and uninformed men who seem to fill so many of our local councils. Their one aim seems to be to make tours of inspection to see things they do not understand, and they return just as wise as they set out, and all the more confused as to the system they should adopt. If they would accept once for all that electrical distribution is *un fait accompli*, just as much as steam power, they might get something done. The sight presented at this end of the 19th century by some of England's local authorities is indeed pitiable.

BUSINESS NOTICES, &c.

Annual Outing.—On Saturday, September 9th, the employés of the British Thomson-Houston Company, Limited, to the number of 65, went to Bournemouth for their third annual outing. On arrival, the party adjourned to the handsome dining room of the Grand Hotel, where a sumptuous repast was served. Mr. Ireland, of the supply department, presided in the absence of Mr. Monks, managing director. Mr. Ireland in his remarks said, among other things, that the B.T.H. would shortly put a cricket team in the field. We are also pleased to note that it is proposed to have some B.T.H. smoking concerts this winter. After the banquet the party assembled on the lawns of the Grand Hotel, where they were photographed.

Book Received.—"Télégraphie et Téléphonie," by J. Pierart. New edition. Brussels: Hayez, editeur.

Sydney. Elec. light fittings. Value £25

The American Electrical Trade.—The *Electrical World and Engineer* says that a large quantity of new work is opening up in the electrical field as the fall season begins, giving promise of a very active winter. There would be even more if the prices of steel and iron and copper had not run to such an inordinate height, but it begins to look pretty certain that copper will have to come off its lofty perch and that electrical industries will not much longer be hampered and held back by the cost of their raw materials. It is hard to tell just how much new business is checked in this way, but the percentage is definite. In some respects, the "going slow" has done no harm, but has given the electrical factories a chance to get belated orders cleaned up, and a fair preparation made for future contracts.

Bankruptcy Proceedings.—A receiving order has been made in the case of J. Stewart Edwards, electrical engineer, Moorgate Street, E.C. The first meeting and public examination will take place on September 19th and October 18th respectively, at Bankruptcy Buildings, W.C.

In *re* the petition in bankruptcy of Mr. S. F. Walker, carrying on business at Severn Road, Cardiff, as electrical engineer, under the name of "Sydney F. Walker & Co.," the first meeting of creditors was held on Monday at the offices of Mr. George David, the Cardiff official receiver. Debtor attributed his failure to "want of capital and illness in August, September, and October, 1898," and returned his liabilities at £2,729, of which £1,923 7s. 10d. is expected to rank for dividend; the deficiency is £1,862 16s. 11d. According to the observations of the Official Receiver, the debtor commenced business at Nottingham in 1876, with a capital of £500. In 1882 he entered into partnership with a Mr. F. G. Oliver. The business was then extended to Nottingham, Cardiff, and Newcastle, and it was carried on jointly for seven years, when the partnership was mutually dissolved, Mr. Oliver paying the sum of £1,000 and Mr. Walker taking over the whole of the assets and liabilities. The debtor had 23 apprentices when he filed his petition, and preferential claims for over £650 are likely to be made for the return of premiums. Mr. C. E. Dovey was appointed trustee, and a committee of inspection was nominated.

Liquidations, Dissolutions, &c.—Messrs. W. H. Clegg and C. D. Falcke (Birmingham Installation Company), electrical engineers, have dissolved partnership, and Mr. Falcke will continue the business under the same name and will attend to debts, &c.

The Railways Electric Supply Syndicate, Limited, has decided to wind up voluntarily, and Mr. F. B. Townsend, of 24, Queen Victoria Street, E.C., has been appointed liquidator.

Creditors of Nernst Lamp, Limited, are required to send their names and the usual particulars to the liquidator, Mr. W. Chaplin, Dashwood House, E.C., by October 21st.

Bristol.—Messrs. Gilbert J. Lloyd & Co., of Bristol, who are very busy in that neighbourhood, have recently received a contract for an installation for Messrs. C. Baylor & Co.'s new factory at Easton for 400 lights. Current will be supplied from two dynamos. The wiring is being carried out in duplicate throughout the building, so that if one machine fails, every alternate lamp is extinguished only. Wiring is being done on the 5-ampere distribution system.

Catalogues, &c.—Messrs. Mather & Platt, Limited, have in circulation a very nicely printed leaflet illustrating one of their multipolar dynamos coupled direct to a vertical engine, also giving general particulars and dimensions of same.

Digitized by Google

We have received also from the same company a copy of a small illustrated pamphlet describing the marine type of engine which they have manufactured in considerable numbers during past years. The standard sizes embody all the improvements in design and construction, which several years of experience and careful observation have demonstrated as advantageous. The engines are specially suited for various classes of work, and being of an open type, all parts are easy of access and supervision; they have a low steam consumption and are arranged to run at a moderate rate of speed. A special type of electrical machine has been constructed for mounting upon the extended bed of this class of engine, the generator being driven direct from the engine, and running at the same rate of speed. Large numbers of these combined plants are now at work in various parts of the world and giving very great satisfaction. In the latter portion of the catalogue, is found a description of a few small sizes of enclosed engines, which have been designed to meet the requirements of customers. All particulars of sizes, weights, and overall dimensions are fully given. The list contains some good illustrations.

The Stilwell-Bierce and Smith-Vaile Company of St. Louis send us a list of the Victor atmospheric water cooling towers and condensers.

Mr. C. R. Heap, of Victoria Street, S.W., sends us a mounted and varnished sheet of illustrations for the wall, showing some of the standard types of C. & C. and Wagner machines.

Claim against India-Rubber Company.—An application came before Mr. Justice Kenny at Dublin last week in the case of William Cameron *v.* India-Rubber, Gutta-Percha and Telegraph Works Company. Although the case can hardly be called an electrical one, it is of interest to mention its character. Plaintiff, of Newry, claimed damages for breach of contract to manufacture and sell a pneumatic shin pad, and to pay the plaintiff a royalty of 10 per cent. The amount of the claim was £50,000, this being arrived at by calculating that there are a million football players, and each pad would sell at 4s.!

Connolly v. Lovelock.—At the Shoreditch County Court, on 25th ult., this interpleader matter came before Judge French. Mr. Alec. Neilson appeared on behalf of the plaintiffs, and submitted the claimant to a stiff cross-examination. This elicited the fact that the claimant was the father of the defendant Lovelock, and he had permitted the defendants to use his works when they had any jobs requiring a big lathe or machinery. He swore that he had nothing to do with Lovelock, Seabourne & Lee, and that he was not, and never had been, a partner in that firm, and, moreover, that he carried on a different kind of engineering business which had nothing to do with electricity, consequently he could not have had the benefit of the goods. He knew nothing about 8, Jeffery's Square, and had only been there since this action was commenced. The Judge, in the absence of any evidence connecting J. F. Lovelock with the defendant firm, consequently found for the claimant with costs.

Deed of Assignment.—Notice is given to creditors of S. B. Apostoloff, of 5, Fenchurch Street, E.C., to send particulars of their claims to the trustee on or before October 15th next. For further information, see our business columns.

Incandescent Lamps.—Messrs. Philips & Co., of Eindhoven (Holland), who are represented in the United Kingdom by Mr. G. Braulik, send us a copy of their catalogue of incandescent lamps. We understand that the firm's works have been largely extended recently, and a first-class staff of 450 men, including eminent technical men, is engaged at the works, the buildings of which now cover 4,500 square yards. Messrs. Philips claim that high class quality and low price have built up the large lamp business which they are now conducting. Lamps of 15,000 C.P. are turned out daily. The firm has just brought out a new high voltage lamp with two short unsupported spiral filaments. It is said to be quite new in construction and there is a good demand for it. A prominent feature of Messrs. Philips's business is the manufacture of special lamps for illumination purposes, for which a new lamp has been recently introduced. The method of manufacture consists of taking a tubular lamp with bayonet cap so made that it is possible to screw a coloured bulb directly over the lamp without interfering with the shadeholder, &c. It is therefore claimed that they may be used for theatre and saloon lighting and garden illumination without interfering with the Bohemian glassware or shadeholders. The catalogue before us contains illustrations of incandescent lamps of all shapes and sizes, fancy and otherwise.

Ross v. National Telephone Company.—In the cause list for the Vacation Court at its sitting on Wednesday (6th inst.) A. Ross *v.* The National Telephone Company, Limited, and T. K. Ross *v.* The National Telephone Company, Limited—which were both motions for injunctions to restrain trespass on plaintiffs' land—stood for hearing before Mr. Justice Cozens-Hardy. Counsel, however, intimated that the matter had been settled on terms between the parties and there would be no order.

Soldering Paste.—Messrs. Beanland, Perkin & Co., of Leeds, send us a sample of Burnley's soldering paste, for which they are the sole English agents. This preparation is in very general use in the United States. Messrs. Beanland are supplying it regularly to prominent electrical firms in this country, including Messrs. Johnson & Phillips, Siemens Bros. & Co., and Mather & Platt, &c. Small samples will be sent upon application.

Trade Announcements.—The firm of Julius Sax & Co., Limited, having gone into voluntary liquidation, we have received notice that Messrs. E. Bulstrode (general manager), Thos. Wilson (accountant), E. Buhler (chief engineer), W. Krause (second engineer), and John Plumb (manager of installation department), being the heads of the various departments named, have formed themselves into a syndicate to carry on the business of electrical engineers and electric light contractors (the Saxon Electrical Engineering Company) at Gervase Works, Gervase Street, Old Kent Road, S.E., assisted by several of the late employés of the old company, and working on the same lines.

Messrs. Boulton & Wade, patent agents, Hatton Garden, have taken into partnership Messrs. B. E. Dunbar Kilburn, M.A., and W. J. Tennant, A.M.I.Mech.E. The firm will in future be known as Boulton, Wade & Kilburn.

Messrs. Chamberlain & Hookham's London testing station and depôt at 6, Cecil Court, has been removed to Messrs. Venner & Co.'s new premises at 6, Old Queen Street.

Wiring Contracts.—The British Electric Installation and Maintenance Company, of Blackheath, have secured the contract for lighting the extensive premises of Messrs. Chiesmann Bros., drapers, and furnishing warehousemen, of High Street, Lewisham. They have also received the contract for the lighting of the Parish Church of Lee (St. Margarets).

ELECTRIC LIGHTING NOTES.

Aberdeen.—There is a deficit of £203 on the first seven months of the current year; the output during that time has increased 36 per cent. It is anticipated that the deficit will be annulled by the end of the year.

Mr. Bell, the electrical engineer, has issued a circular to the electricity consumers, stating that when anyone wishes to use a large number of lamps for a special display, he may, on giving 24 hours' notice, have his demand indicator cut out of action, so as not to increase the price charged for the whole supply for the half-year, provided that this does not occur oftener than once a month. We commend this very reasonable arrangement to the notice of supply engineers. It is a small matter, but may obviate much dissatisfaction.

Accrington.—The Board of Trade has decided to allow the Corporation's provisional order to remain operative, seeing that steps are being taken to provide electricity works.

Bristol.—At the Bristol City Council on Tuesday afternoon, Mr. George Pearson moved the adoption of a report from the Electrical Committee recommending the purchase of over nine acres of land for a new generating station, the rapid progress of the demand for electricity having almost exhausted the capabilities of the site already in use. The proposal excited some surprise in Bristol, where, during the recent controversy with the tramway company, so much had been heard of the advantages of combining electrical and power stations. The tramway company's power house is being erected close to the civic electrical works, but the new Corporation station now proposed is in another part of Bristol—perhaps three-quarters of a mile from the existing works, and on the south-eastern edge of Bristol. The explanation for the new proposal was that the progress of the electrical undertaking had greatly exceeded the estimate formed at the time when it was established, and the capacity of the works at Temple Backs, although increased by the addition of adjoining land, is insufficient to supply more than the present demand, while the proposed extensions of the land recently sanctioned will not suffice for more than one year's additional growth. The committee found it, therefore, necessary to prepare for a considerable extension of the undertaking. They failed to find land in the neighbourhood at a price they could recommend the Council to pay, and ultimately selected a site at St. Philips Marsh, costing roundly £15,000. The property has good approach from road, water and rail, and Mr. Pearson explained that it would permit an extension of business 10 times as great as that already done. In commenting on the position in which the committee found themselves, Mr. Pearson said the committee commenced in 1893 in a very small way with 16,000 lamps. In March, 1899, their lamps numbered 68,000, and at present the aggregate was 74,484. They commenced by selling 300,000 units in the year, and last year the sale amounted to 1,362,000 units. The revenue grew from £6,624 in the first year completed to £26,233 last year. With the growth of revenue and output the cost of production had decreased from about 4½d. to not quite 2½d. The profits at first—if a Hibernianism would be allowed—were a loss. The profits last year carried to the net revenue account were £12,630, from which had to be paid interest and sinking fund. It was said that it was improper for a municipal authority to talk of profits until interest and sinking fund had been met. He dissented from that view. No one would dream of saying a public company must not speak of its profits until it had paid its debenture interest and dividends on its shares. He considered the profits they might legitimately consider as profits were what they transferred from the credit of the general revenue account to the net revenue account. They had made a profit notwithstanding a reduction in the cost to private consumers and for public lighting. It showed they had got hold of a good and a growing undertaking, and the growth justified the large proposal he asked the Council to adopt. If they did not hand over actual cash to the city they were benefiting the citizens by reducing the cost. The new site would be equal to supplying 800,000 lamps, or rather more than the total number of gas lights in the city. The site would have an advantage compared with the former one that piling would be less expensive and a river wall would not have to be built. There was the important disadvantage—a division of their work and the cost of working two establishments instead of one. He had asked their engineer what he suggested, and the engineer said the best method

Digitized by Google

would be to use the present site for the day load, their power and their public lighting. They would want three shifts as at present. He would propose to use the new station to supply their heavy load in times of pressure, and as a stand-by in case of breakdown at the older station, and for that purpose one shift only would be needed. They had proceeded so far in the extension of their mains very much on the principle of supply and demand for the moment, but now their business was getting so big they ought not to proceed on such haphazard lines, and they should lay down for themselves—though they might not carry out the works at once—certain lines on which they would proceed. As to the cost of current, it would be their duty to see if they could not at no distant date reduce the price of public lighting. They had made mistakes, no doubt, but when they had done a stupid thing they thought it best not to advertise the fact, and he should not, therefore, take the Council into his confidence on that matter. He would, however, say they hoped to see the cost of production considerably reduced, their coal bill reduced, and their output increased.—During the discussion on the report, an appeal was made to the Electrical Committee by members of the Libraries Committee to light the libraries with electricity at a lower cost. Mr. Pearson replied that if the electric lighting of the libraries cost more than gas lighting, there must be waste somewhere. He had the light in his own house, and he had more lamps than ever he had, and his last bill was less than his last gas bill. The Council adopted the report.

Messrs. Mindham & Co., of the Western Electrical Works, have secured the contract for lighting St. Stephen's Church, one of the oldest historic churches of this city. They have also in hand several important electric lighting contracts, including a large new Nurse's Home in connection with the Bristol Royal Infirmary; a large new suite of offices, and several steamships that are now running from this port.

Bucksburn.—A meeting of the ratepayers was held last week to consider the electric lighting scheme for the village, proposed by Messrs. P. C. Middleton & Co., electricians, Aberdeen. The firm offered to pay £50 per annum for the surplus water at present running from the turbines of the Waterton district supply, as well as to erect a house for the official who would have charge of the lighting station, and to pay his salary. They were also prepared to supply 60 street lamps of 16 C.P. at 25s. 6d. each per annum. The light would be provided for nine months of the year, and the contract between the district authorities and the electrical engineers would be binding for 21 years. A resolution was unanimously passed to take the necessary steps for forming a special lighting district.

Cheltenham.—Residents in Cleeve Hill want a supply of electric current. The Council is willing to undertake this when powers have been obtained.

Chorley.—Messrs. Lacey, Clirehugh & Sillar have been requested to report to the Council on the subjects of electric lighting, traction, and refuse destructor.

Colchester.—The Local Government Board has sanctioned the proposed loan of £6,500 for electric lighting purposes, the money to be repaid in 25 years.

Coventry.—The electric lighting of the new extensions to the cycle works of Messrs. Rudge Whitworth, Limited, is being carried out by Messrs. Ellis & Ward, electrical engineers, of Birmingham. The plant consists of upwards of 200 incandescent lamps and several arc lamps. Arrangements are also being made to supply the lift, which is one of Messrs. Waygood's, with electric power.

Darlington.—The Town Council has received sanction from the Local Government Board to the borrowing of the sum of £25,940 for electric lighting purposes, such sum to be repaid within a period of 25 years. The question of the town supplying electric power to the tramway is being considered.

Darwen.—We hear that the electricity works have been so far completed as to allow a supply of current to be given for private lighting. Street lighting will commence in about 10 days or a fortnight.

Dawlish.—The District Council has accepted Messrs. Taylor & Field's offer to report on the electric lighting of the town for 20 guineas.

Dewsbury.—The Local Government Board has intimated to the Town Council that before sanction can be given to the borrowing of £9,060 for the purposes of electric lighting, it will be necessary to obtain the permission of the Board of Trade to the alteration of the standard pressure on the mains.

Dorchester.—The Edmundson Electricity Corporation having given notice to the Council of their intention to apply for a provisional order to light the town, it was decided to oppose on the grounds that the Town Council intended introducing the electric light into the borough in the near future.

Dundalk.—Representatives of the Irish Development Syndicate have had a private interview with the Dundalk Urban Council with reference to the terms of transfer of the electric lighting powers of the Council to the Electric Tramways Company. The proposal to construct and work a system of electric trams for the town and its seaside neighbour Blackrock, and to combine with this undertaking the electric lighting of the town, was made a considerable time ago, but difficulties arose as to the terms on which the provisional order obtained by the Town Commissioners should be transferred. It is now stated that the basis of an agreement has been arrived at, and that work will shortly be commenced on the construction of the tramlines and works.

Erith.—The Urban District Council have instructed Mr. W. C. C. Hawtayne to prepare plans for the generating plants and mains, they having decided to take steps to establish a municipal electricity supply for the district upon the basis of Mr. Hawtayne's scheme, dated June, 1898.

Farnworth.—Messrs. Lacey, Clirehugh & Sillar have received instructions from the Urban District Council to proceed with the scheme for lighting and traction.

Festiniog.—A special meeting was held last week to consider the desirability of lighting the district by electricity. After some discussion, it was resolved that the Council apply to the Board of Trade next session for a provisional order with the view of carrying out electrical supply works for the district. Mr. T. J. Warden Stevens was appointed out of seven candidates to prepare a report upon the matter.

Fort William.—The Electric Light Company's annual report has just been published, and is of an encouraging nature. During the past year the electricity supply has been extended to the villages of Banavie and Corpach. By arrangement with the Burgh Commissioners the company has acquired the use of the surplus water supply of the town, and has erected an additional turbine.

Frimley.—The District Council has appointed Mr. F. H. Medhurst to report on the subject of electric lighting.

Gillingham.—The District Council has resolved to enter into an agreement with Mr. Jasper for the supply of electric light to arc lamps in the public street at 2½d. per Board of Trade unit; the lights will be turned out at 11 o'clock.

Grimsby.—The Public Lighting Committee has issued invitations for laying the foundation stone of the new electricity works by Alderman Dobson, on Thursday, October 5th, at 2 30 p.m.

Hales Owen.—The District Council approached the Gas Company with a view to purchase; the company demurred to the proposals, and now the Council has invited the British Electric Traction Company and the Midland Electric Power Distribution Company to discuss the question of taking over the Council's powers for electricity supply.

Harrogate.—The Gas and Electric Lighting Committee have resolved that from January 1st next the rate of charges to consumers of electric light be as follows:—Under 15,000 units per annum, on the demand indicator system, at 6d. per unit for the first 1½ hours, and 3d. per unit afterwards; over 15,000 units per annum, on the demand indicator system, at 6d. per unit for the first hour, and 2d. per unit afterwards.

Heywood.—The Electric Light Sub-committee advises that Mr. W. P. Adams, of London, be appointed consulting electrical engineer, and that his scheme be adopted. The scheme provides for the erection of works on the new town's yard site in Hind Hill Street. The works are to be capable of meeting the estimated demand for the first two years and are to be so arranged as to be easily extended. They will also be so arranged as to enable the works to supply power for traction.

Ilford.—Colonel A. C. Smith, R.E., held a Local Government Board inquiry at Ilford last week into the Council's application for sanction to borrow £4,000 for site for depôt, electric lighting, and tramway station. There was no opposition.

Inverness.—The proposal to utilise water-power from the Caledonian Canal for electric lighting purposes has fallen through. The Council has decided to adopt steam-power, and has appointed Mr. Craven, Edinburgh, to draw up plans and specifications for a suitable scheme.

Lerwick.—At the monthly meeting of the Burgh Commissioners last week, a report by Mr. R. F. Yorke, electrical engineer, Glasgow, was submitted as to the proposed introduction of the electric light into Lerwick. Mr. Yorke finds that the Sandy Loch, from which the water supply of the town is at present drawn, contains sufficient surplus water for motive power purposes, and would give 80 H.P. for six hours per day, the gross fall being 220 feet. He recommends that a turbine house should be built at the Loch Clickimin, which would involve the laying of a 16-inch pipe from the Sandy Loch to that point, a distance of about 2,000 yards. In order to avoid drawing too largely on the Sandy Loch during the summer time, the engineer proposes to utilise a smaller loch near to it, by which means an additional storage would be obtained of 6 feet over the whole area, which he estimates would be capable of giving sufficient water in summer for, say, a period of three months. The electric current will be conveyed from the turbines to the accumulator house at Union Street. The total cost of the undertaking is estimated at £9,260, and the working expenses, including interest and sinking fund, at £967. The revenue from the public and private lighting, charging 6d. per unit, is estimated at £1,720, leaving an apparent surplus of about £760 per annum. The present price of gas in Lerwick is 7s. 6d. per 1,000 feet. Before discussion, it was decided to circulate the report among the commissioners prior to next monthly meeting.

Llanrwst.—At Llanrwst Urban Council a letter has been received from the Electricity Supply Company, regretting that owing to inability to get delivery of required material, they were unable to give light by the specified date, but stating that they were doing all they could to give the light as early as possible, and should the delay inconvenience the Council, promising to "meet" the Council with a corresponding reduction in price.

Digitized by Google

London.—At the St. George's-in-the-East Vestry last week, a letter was read from the County of London Company intimating that they were going to commence laying the mains for the electric lighting in the main streets in the district.

Manchester. — The Electric Light Committee is to borrow £5,000 for transformers, meters, &c., required during the next 12 months.

Merionethshire.—At Dolgelley, the county town of Merioneth, a decided move is being taken to light the town by electricity, and a comprehensive scheme is likely to be placed before the next meeting of the District Council. It is stated that the Council now pay £150 per half-year for lighting, and that they can borrow £2,500, and only pay £150 in interest.

Nenagh.—The Town Commissioners are considering the question of electricity supply. The feeling of the town is entirely in favour of electric lighting, the prevailing idea being that neither the municipal body nor private consumers are being favourably treated by the gas company.

Newport.—Mr. H. M. Taylor, the assistant electrical engineer, having resigned his appointment, the Committee met recently to consider the question of rearranging the electrical staff. It transpired that the working of additional plant now being laid down would necessitate further assistance. It was resolved not to fill the vacancy caused by Mr. Taylor's resignation, but to appoint two additional electricians at a salary not exceeding £2 per week each, and to increase the salary of Mr. C. D. Copland, the borough electrical engineer, from £225 to £300 per annum. At a subsequent meeting, the chairman, Alderman John Moses, said that he could not be a party to this arrangement, as it would throw increased responsibility on him, and he therefore resigned his position.—The borough electrical engineer submitted his usual report upon the condition of the plant and machinery. A comparison of the plant with the number of lights showed the plant to be overloaded. The office manager submitted his report as to the progress of the business for the month of July, based upon the number of units generated, showing a satisfactory rate of increase. He also presented a report of his canvass during the past month, from which it appeared that he had obtained orders for new connections equivalent to 278 lamps, bringing the total connected and on order up to 30,380 8-c.p. lamps. The question of reducing the charges for electric energy for motive power so as to meet the large consumption required by Messrs. Griffiths & Sons (clothiers and manufacturers), who intend to put down additional motors, was considered. The present charge is 2d. per unit for a consumption of 3,000 units per quarter. It is understood that Messrs. Griffiths would require about 7,000 units per quarter. It was resolved that the scale be extended so that the charge to all consumers shall be 1½d. per unit for a consumption of 3,000 units per quarter and upwards, provided that Messrs. Griffiths will enter into an agreement to take the energy required for the additional plant they are about to lay down. The station emergency plant is shortly to be sold for £750. As it is impossible to make two of the underground sub-stations watertight, they are to be rebuilt above ground.

Nottingham.—The net revenue of the electrical department, after payment of all charges, was for the past year £3,576. The total profit for the year on an income of £12,847 was £7,776 2s. 4d., but this was subject to the deduction of £4,200 for the contribution to the sinking fund and for interest on loans, &c.

Oldham.—Smoke nuisance from the Corporation electricity works gave rise to a brief discussion at a meeting of the Sanitary Committee.

Paisley.—The electricity works was formally opened on Tuesday last week. The capacity of the works is at present 1,000 H.P., but tenders for additional machinery are to be invited shortly. The total expenditure, so far, has been £53,000. Mr. Francis Teague, formerly of Coatbridge, is in charge of the work, which has been carried out under his supervision.

Penmaenmawr.—At Penmaenmawr the Urban District Council has received a letter from a firm of Worcester electrical engineers, suggesting that the district is particularly well placed and situated for electric lighting. The town water supply could be used for producing the power, and so the streets could be lighted without cost, and a revenue would probably accrue for a reduction of the rates. The matter has been referred to Committee.

Plymouth.—The opening of the electricity works in Plymouth, and the formal installation of the electric light and tramway, have been set down for the 25th inst.

Rochdale.—The Town Council has decided to borrow £30,000 from the Public Works Loan Commissioners for the purpose of the electric lighting in the borough.

St. Pancras.—The Electricity and Public Lighting Committee informed the Vestry on Wednesday of having accepted numerous fresh applications for current. Dr. Walter Smith, chairman of the committee, explained that the requirements of the new customers were equivalent to 500 amperes, thus showing that the undertaking was progressing rapidly. On the recommendation of the committee, the Vestry resolved to apply to the Board of Trade for a license under Section 3 of the Electric Lighting Act, 1882, to supply electricity in Brecknock and York Roads in accordance with the consent given by the Islington Vestry, and to convene a special meeting of the Vestry to pass the necessary resolution in regard to the matter. The Vestry sanctioned an expenditure of £1,661 on laying new mains, accepted the resignation of Mr. R. Minchin, one of the electricians at the Regent's Park station, and granted him a testimonial.

Sale.—The Town Council has rejected a proposal to lay down a municipal installation, and having read Mr. Charles Hopkinson's report, has resolved to approach the Manchester Corporation and the Altrincham Electric Supply Company, with a view to obtaining a supply of electricity in bulk at 3d. per unit.

Ventnor.—The Works Committee on 4th inst. recommended that the District Council should accept the tender of the electric light company for lighting the whole district, at the annual rate of £15 per arc lamp and £2 10s. per incandescent lamp, £707 10s. altogether. The Council asked for an alternative scheme omitting the arc lamps.

Walthamstow.—The Local Government Board has sanctioned the Council's £5,500 loan for the electrical wiring of houses in the district.

Warrington.—The Council is making application to the Local Government Board for sanction to a £44,966 loan for electric lighting.

Welsh Quarry Districts.—At Festiniog (the capital of the Welsh quarry trade) the District Council have decided to apply to the Board of Trade next session for a provisional order to light the district with electricity. Some of the works in the district already make use of the light.

West Glamorgan.—Arrangements are understood to be in progress for lighting Clydach, a populous district in West Glamorgan, by electricity.

Whitby.—The Council has adopted an electric lighting scheme drawn up by Messrs. Preece and Cardew, the total expenditure being £18,500. This scheme was adopted in preference to a £26,000 one.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Blackpool.—Last week the Council adopted the recommendation of the Electric Lighting and Tramways Committee that the tender of the Barrow Hematite Steel Company, Limited, for the supply of steel rails and fishplates required in the construction of the tramways through Claremont Park be accepted; also the tender of the British Thomson-Houston Company, Limited, for the electrical equipment (except the sand blowing) of the 10 new tramcars now in course of construction. Alderman Brodie, in moving resolutions to this effect last week, referred to the delay in certain work, and apologised for the unfinished state of the trolley heads. It was the difficulty experienced in obtaining materials that caused the delay in the progress of the tramways. They had commenced the overhead system six months before they should have done, but it had been beneficial to the town. It was very gratifying to find that their takings were £4,000 more than they were in the corresponding period of last year. There was every reason to believe that if they had double lines they would do a great deal more on the front. They were told that they did not want any more power, though they were now driving 30 cars by the overhead system against 18 by the conduit system. They instructed Mr. Quin to get out a scheme for going round Marton. They should want more power then, but it would be well worth the money. It would be advisable to take into consideration the question of 1d. stages for next year. The Claremont Park tramways will cost about £18,000.

Boston.—The British Electric Traction Company has written to the Council with reference to the establishment of a service of electric tramways from the Sleaford Road to the Wainfleet Road, or to the Dock, and the letter has been referred to the Paving and Lighting Committee for consideration.

Burnley.—The Tramways Committee has recommended the Town Council to seek in the next session of Parliament the requisite powers to convert the existing tramway within the borough, after its acquisition by them next year, into a double line, as far as practicable, and to include powers to construct tramways in the Burnley Wood district, Manchester Road district, and Accrington Road (with a view to an extension to Lowerhouse).

Dalmuir.—The Glasgow Corporation is considering the advisability of extending the tramway to Dalmuir.

Darwen.—The Tramways Committee has decided to order 10 cars, five from each of two firms. The cars will in many respects be similar to the Blackburn cars, and will be run under the management of the Blackburn Committee. The Committee thought that formed a fair basis, which would endure until the cars were electrically equipped, and after that they would have to make a permanent arrangement. It was estimated that the completion of the line would take place in about 12 months.

Failsworth.—The Manchester Corporation has advised the District Council that the latter would shortly have to give notice to the Manchester Carriage and Tramways Company for the purchase of the lines within the district. The chairman said it was for that Council to give notice, and carry out the transaction; but the Manchester Corporation would be the real purchasers, as they had an agreement to work the trams after the conclusion of the transaction. A special meeting will be held to consider the matter.

Digitized by Google

Grimsby.—The Town Council has decided to adopt an agreement with the Great Grimsby Streets Tramways Company, whereby the present lease to the company has been extended for 21 years. The agreement contained conditions *re* extensions of the line, and supplying of electrical power by the Corporation to the company.

Hungary.—The Raab-Oudenburg-Ebenfurth Railway authorities are about to carry out some trials of accumulator traction on their line between Kleinzell and Esterhaza.

Isle of Man.—The Tramways Company is still going ahead; a turbine is to be put down at Laxey to supply power to the line during the winter season, and also to assist in the summer. It is anticipated that a great economy will be effected in this way. A deputation from Belfast Corporation visited the island last week and inspected the whole of the tramways.

Limerick.—The city engineer has presented a report to the Corporation on the proposed electric tramway scheme, in which he points out that the promoters have made no offer of wayleave, whereas in Belfast the company pays £4.000 a year, and in Dublin £500 per mile, or a minimum of £10,000 per annum; in Cork, however, no charge is made. The engineer enumerates various conditions, which should, in his opinion, be imposed on the company, one of which—that the latter, if called upon by the Council, must introduce any new system of electric traction instead of the then existing system—appears to us to be unnecessary and unreasonable.

Liverpool.—At last week's City Council meeting the Electric Power and Lighting Committee recommended the Council to enter into a contract with Messrs. Willans & Robinson for the supply for the Lister Drive and Cobbs Quarry Stations of four 3-V triple expansion engines, each coupled to a multipolar dynamo of Siemens' make, for the sum of £6,939 each set, and three 3-H.P. compound engines, each coupled to a two-pole dynamo, for the sum of £1,377 each. Mr. Rutherford wished to know what sort of engines they were to be, and what their horse-power was to be. Mr. Petrie, as ex-chairman of the committee, said that some two years ago the subject of these engines was fully discussed in the Council, and a certain type of engine was adopted for certain valid reasons. These were the engines which it was now proposed to buy, as being those which, in the opinion of experts, were the best suited to these stations. [It was here discovered that a quorum was not present, and therefore the matter could not be decided.] Mr. Petrie said that unless this contract were soon entered into, the whole of the electric tramway system would be delayed unduly, and he hoped that a Council meeting would be held as soon as possible to deal with the subject.

Some opposition has been raised by commercial interests to the introduction of electric traction into certain streets, where it is feared the heavy traffic of the port would be hampered by the tramcars. The matter will be considered at a special meeting to be held on October 11th.

Newcastle-on-Tyne.—At last week's City Council meeting Mr. Cail presented the report of the New Tramways Committee. The report stated that on February 21st the Council adopted the overhead trolley system of electric traction on the tramways with the proviso that the system be not constructed in the streets in the centre of the city until the Council had considered and decided whether in those streets some system of electric traction other than overhead traction was practicable, and could be worked in conjunction with the overhead system in the other streets upon the tramway routes. The New Tramways Committee was requested to get the opinion of experts on the point. Prof. Kennedy had given his opinion that as a matter of mere practicability, the Committee's question must be answered in the affirmative. There were systems, he said, not requiring overhead wires, which could be worked in conjunction with an overhead system, but whether it was desirable for the Committee to adopt a combined system of this kind was a matter which the Committee must decide for themselves. There were several cities in which an overhead system and a conduit system were running together and in connection. In cost of construction they certainly would be more than an ordinary overhead line, but he was sure there would be no special difficulty in working from one system to the other. Mr. Chas. Hopkinson, in his report to the Committee, advised the Committee not to combine the overhead trolley and conduit systems. He advised that the trolley system be installed throughout, but that in the central part of the town, where overhead wires were objected to, it be regarded as temporarily installed, pending proof from prolonged use elsewhere of one or other of the surface contact systems. The Committee, after having given careful consideration to the subject, recommended the Council to adopt the trolley system for the entire tramways in the city, as recommended by Mr. Charles Hopkinson, on the distinct understanding that the trolley system in the central part of the city is to be recognised as only a temporary arrangement in order that the views of those who object to the overhead system may be met when this can be satisfactorily accomplished. It was decided to have a special Council meeting on 13th inst., when the report will be considered.

Oldham.—The Town Council last week discussed the minutes of the Surveyors' and Tramways Committee, which contained the following:—"Resolved, that the motive power to be employed in Oldham be electricity, and that the system be the overhead trolley system."—Alderman Eckersley, in his capacity as chairman of the committee, gave a lucid and exhaustive explanation of the proposed scheme, and made it clear that, as against the alternative plan of the conduit system, the overhead or trolley system of traction was the best for a borough like Oldham. It commended itself on account of its cheapness in construction and maintenance, its simplicity and ease in effecting repairs, and the rapidity with which the lines could be constructed, and the comparatively small interference with the surface of the streets and the traffic. The opposite conditions would, he said, attend the conduit system, in addition to the enormous expenses of construction which it would entail. The borough would scarcely be justified in spending a million of money when a quarter of the sum would suffice to provide a system of traction which, in the future, would not require as much in maintenance as its rival. The minutes were ultimately adopted unanimously.

St. Helens.—The Council is applying for a provisional order authorising extensions of the tramways along certain thoroughfares.

Sheffield.—The Tramways Committee intend to obtain powers for doubling all single lines at any suitable time, to carry goods and merchandise on the tramways, and to construct 11 new sections of tramway.

South Australia.—The Adelaide correspondent of the *British Australasian* says that it is reported that an English syndicate is willing to find the necessary capital to convert the principal tramlines into an electrical system. The proposal is to amalgamate the companies and form one large company, and to subscribe the additional capital required.

Stirling.—The British Electric Traction Company applied to the Central District Committee last week for approval of a scheme for a tramway or light railway from Stirling along the Hillfoot district, on the overhead trolley system. The Committee unanimously agreed to give a general approval to the scheme.

Stockport.—The Council has given notice to the Manchester Tramways and Carriage Company requiring them to sell to the Council so much of their undertaking as is within the borough of Stockport. The Council has adopted a report of the Tramways Committee ordering a survey of certain routes with a view to the introduction into the borough of an electric tramways service, and appointing sub-committees to confer with the local authorities of Reddish, Cheadle, Bredbury, and Bramhall, whose districts adjoin the borough. There was a general expression of opinion that this Committee should prosecute its special work with all vigour.

Swansea.—The relaying of the tramlines is now completed, the poles are in position, and the power station is said to be nearly ready. The cars will complete the system.

Wakefield.—The Corporation is being besieged by applicants for permission to promote a light railway or tramway in and about the town, three communications having been received recently.

West Riding.—The District Councils of Queensbury, Sowerby Bridge and Elland, have been in negotiation with the Halifax Tramways Committee with regard to proposed extensions of the Halifax tramways to their respective areas. Queensbury has also conferred with Bradford as to the junction of the Halifax and Bradford tramways, and Elland is inquiring of the Huddersfield Corporation as to an extension to Elland. Yeadon has invited Rawdon and Horsforth to consider proposals made by the Leeds Parliamentary Committee with regard to the proposed extension from Kirkstall to Yeadon.

Worcester.—Messrs. Kincaid, Waller & Manville have advised the Council to take over the tramways and work them municipally as electrical lines. Their report also referred to the scheme of the Tramways Company, and the light railway extensions, which the company proposes, are said to be really extensions to the existing tramways. The negotiations between the company and the committees were referred to last week. The Council has referred that matter and the report of Messrs. Kincaid to the Joint Street and Electricity Committees for reconsideration. The report says that if the Corporation gave their assent to the light railways scheme, they should be prepared to assent to the Tramways Company having a new tenure in some form of the existing lines. If, on the other hand, the Corporation desired to avail themselves of the powers of purchase in respect of the tramways, there was no question but that the application of the Tramways Company for extensions should be vigorously opposed. They estimated the cost of acquiring and reconstructing the existing tramways, and of making the extensions, equipping the lines with rolling stock, and incidental expenses, at £72,180, without providing for generating plant, or feeders, leaving that important point to be considered in conjunction with the electric light undertaking. They estimated the receipts per car mile at 9d., as compared with 9¼d. given in the company's balance-sheet for 1898. Thus the total receipts on an estimate of 500,000 car miles would be £18,750, to which must be added £500 per annum for advertisements. They put the working expenses at 6d. per car mile, £12,500; interest on £73,000 at 3 per cent., £2,190; redemption of loan, £1,776; total, £16,336. The estimated net profits would, therefore, amount to £2,884 per annum.

Rennes Telegrams.—Reuter's agent says that as many as eight or nine million words were despatched over the telegraph wires from Rennes in the course of the Dreyfus trial, and on Saturday last the telegraph receipts amounted to 450,000f. (£18,000). The number of direct telegrams sent announcing the sentence and verdict was about 3,000.

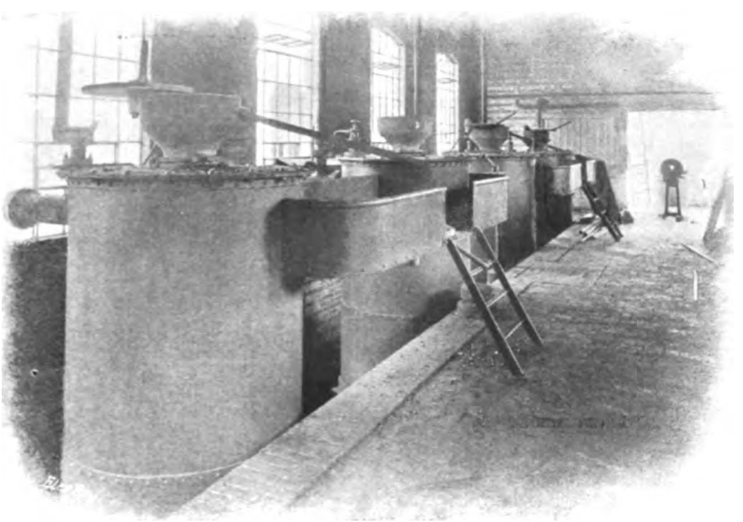
THE LIGHTING OF LYNN.

A mere glance at an ordinary railway map of Norfolk brings home to the mind of the electrical engineer who is acquainted with the course of electric lighting progress in this country what a small amount of such work has, so far, been accomplished within the county. We think of the attempts made by a company to light Thetford, attempts which were not rewarded with sufficient business to allow the continuance of the works, which consequently came under the hammer a few years ago. We think of Cromer, the fashionable and quiet watering place on the north-east, where, although the electrical engineer has done his best during recent years to bring a scheme to a head, nothing has been actually done. There are Hunstanton, Dereham, and a host of other towns, where the electrical engineer has yet to find his way, and this he will probably do within the next few years.



Gas Producers.

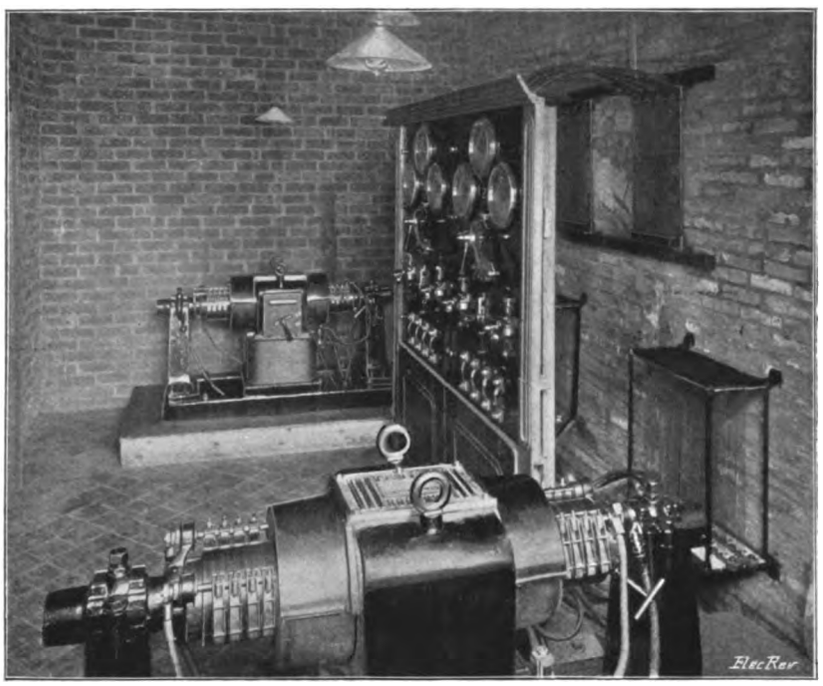
The municipal plant at Great Yarmouth, with its electric tram scheme now working out, and the electricity supply system of the Norwich Company, are satisfactory undertakings. But beyond these, there is practically nothing to speak of, for the county consists of some scores of small villages or towns, the largest of which can boast of only 3,000 to 5,000 population—a population which varies, we should think, very little indeed in the course of the year, save in the case of the more prominent holiday resorts on the coast.

Electrical engineers are so fully occupied with large lighting, traction, and power schemes just now, that it may be

Gas Producer House, Holder, Etc.

Digitized by Google

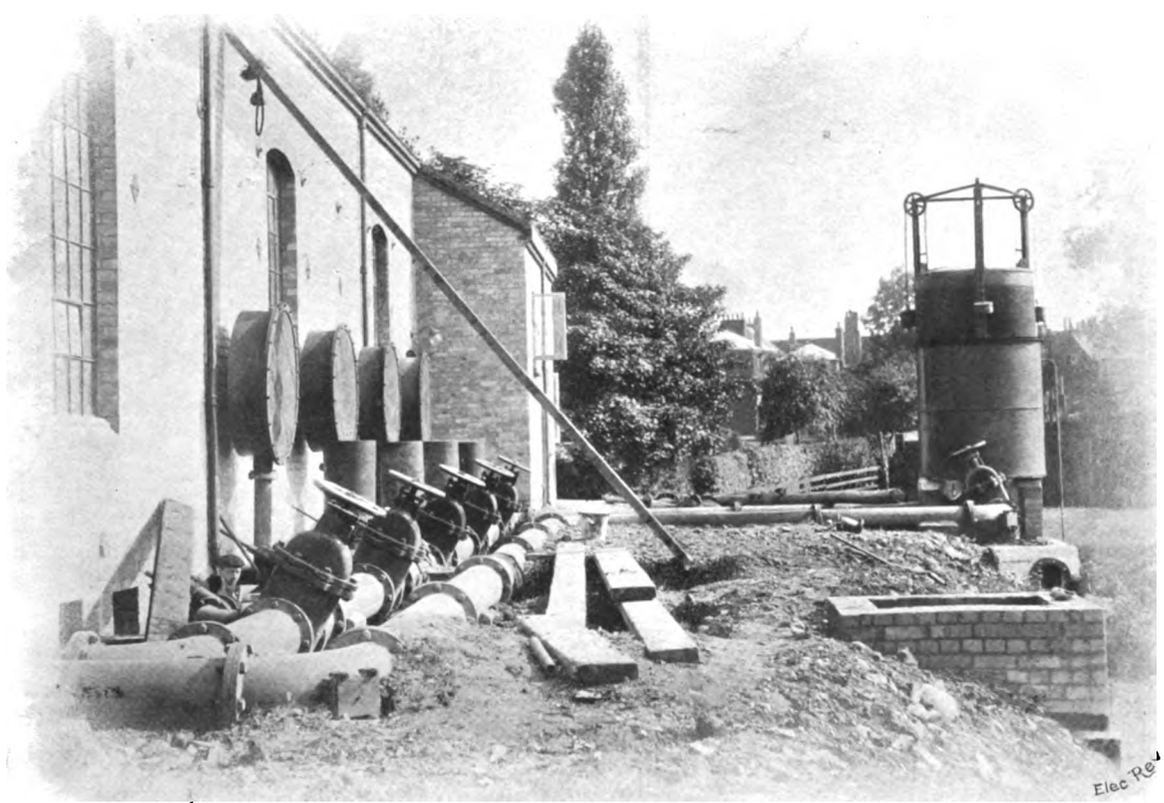
thought to be hardly worth the candle at the present moment to consider the numerous small districts throughout the country. When the needs of larger towns have been attended to, however, the question of electric lighting must be eventually raised, unless gas or oil is for ever to hold sway. There is, of course, the very important question arising as to whether it would pay at all to introduce electric lighting by a public installation into these small scattered, and by no means wealthy, districts until the costs can be reduced to a lower figure than at present. We imagine that the most likely way in which it may be arranged will be for the Yarmouth, Norwich and Lynn, and any other of the larger works to distribute current for meeting the needs of the adjacent smaller places, unless small isolated gas-driven plants can be put down.



Town Hall Substation.

In the preceding remarks we have not made particular reference to the town of Lynn, or King's Lynn, the population of which is somewhere between 18,000 and 20,000; this fact bringing it outside the category mentioned. There seems to be a good future in store for electric lighting here.

We need hardly refer to the history of the negotiations leading up to the adoption of a municipal electrical scheme. The opposition of gas interests is a foregone conclusion nowadays, inevitable as electric lighting is, but at Lynn in the matter of street lighting there is to be a clean sweep made, electricity being adopted throughout, although incandescent gas, which is proving so powerful an opponent—perhaps only temporarily—for street lighting in Bolton, Liverpool, and other towns on account of cost, has been on its trial here for some time. In some streets the mantles are still employed pending the completion of the erection of the electric light standards. It is little consolation to gas interests at Lynn to know that the plant is gas-driven, for while the town supply of gas is drawn upon, this is done only to a very limited extent, as the gas-producing plant installed in accordance with a scheme of Prof.

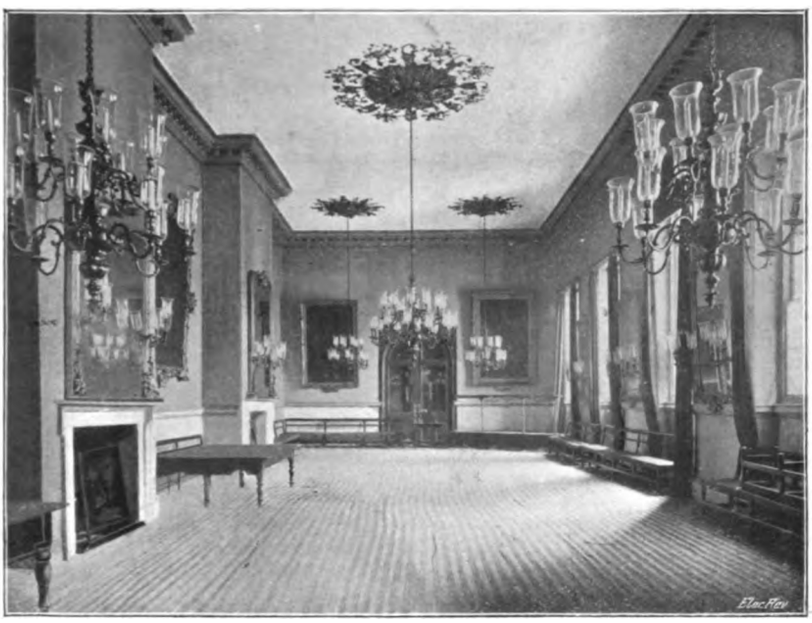


Auxiliary Gas Holder.

Digitized by Google

H. Robinson is primarily responsible for the supply. The gas street lamps are being shut off in batches at certain prearranged periods, and when the electric lighting scheme is completed, there will be electric arc and incandescents for public lighting to the number of about 400.

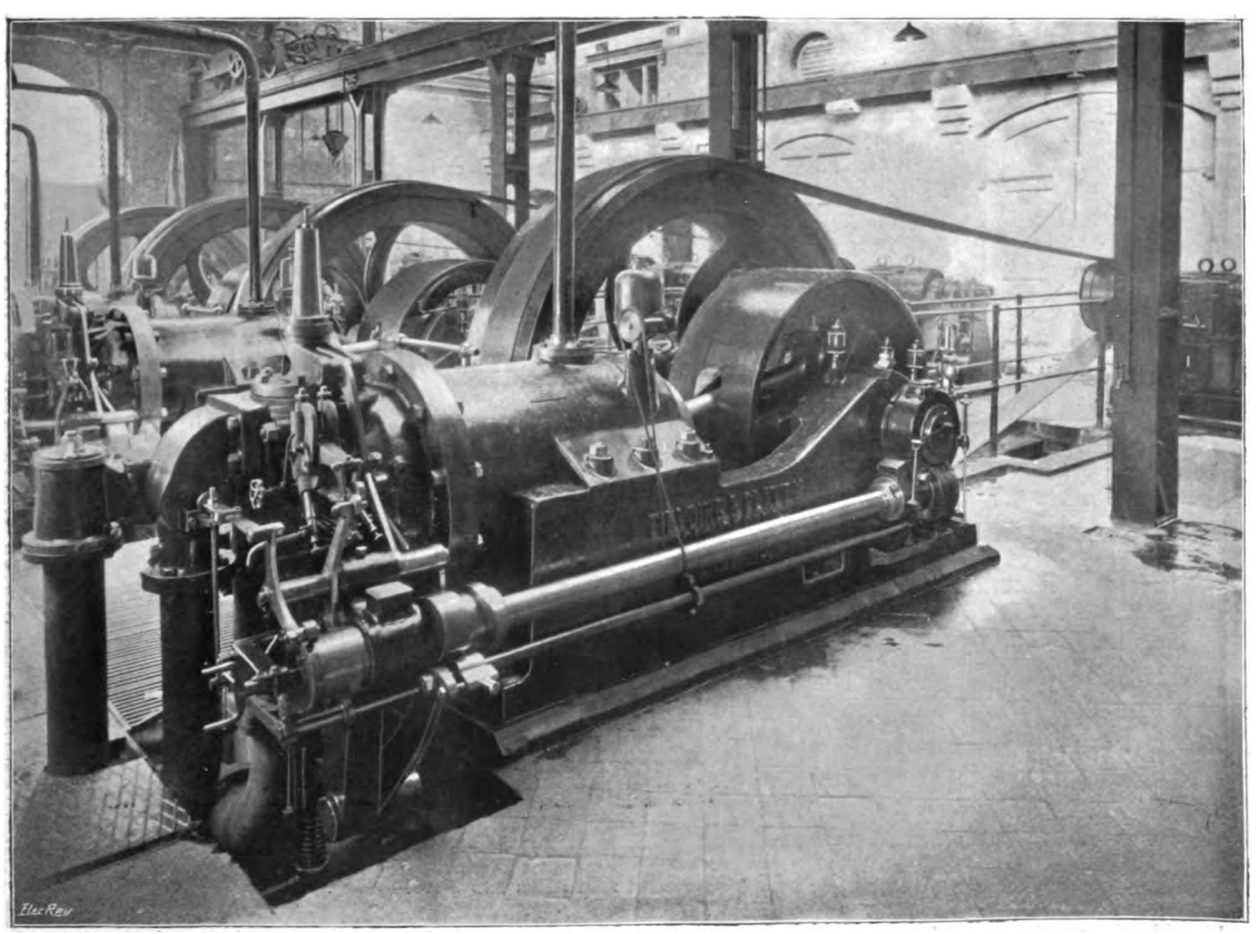
The subject of gas-driven installations is an interesting one. The vicissitudes through which some public works have passed, leading to the abandonment of the Coatbridge and Morecambe plants, and the adoption of steam driving for extensions at Belfast, formed important chapters in the history of this particular class of installation, chapters in which so much has been already written, that we need not enlarge further. The successes of the Midland Railway plant at Leicester must not be forgotten, and more particularly we must not overlook the works of the Leyton Town Council, where Dowson gas plant has been used for the past two or three years in accordance with the scheme drawn up by Prof. Henry Robinson. The generating costs at Leyton have, we understand, worked out at a very low figure.



The Ball Room.

The King's Lynn electricity scheme also has been designed by Prof. H. Robinson, although the equipment differs somewhat, the experience of Leyton working having been taken advantage of. We may therefore hope that the results of the Lynn supply may be equally, if not more, successful.

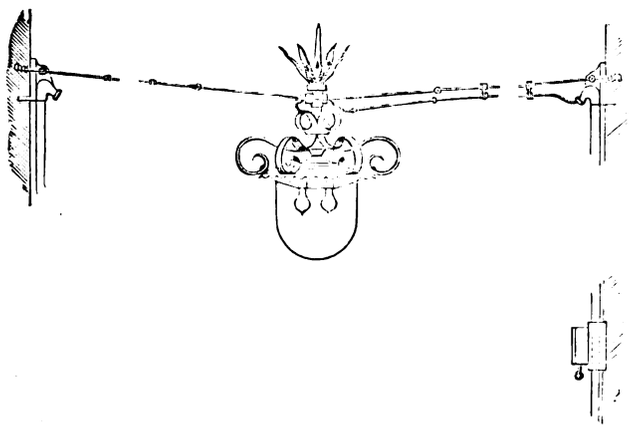
The Lynn contracts were placed just about twelve months ago, and things would have been ready earlier but for the effects of the engineering strike. The total amount of loan raised for the works is about £30,000. The area supplied is a compact one, and the small consumer predominates. Consumers are charged 5½d. per unit, with a discount beyond certain consumptions. The Corporation has its own house wiring department, and it is, perhaps, needless to remark that this arrangement is not



Interior of Station, showing Gas Engine.

Digitized by Google

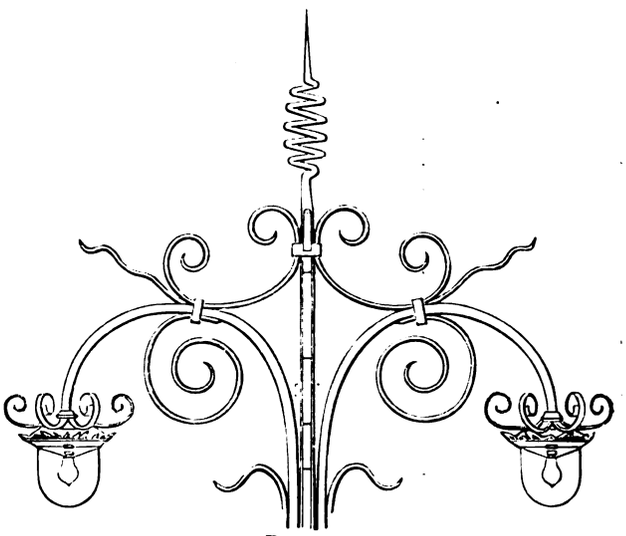
altogether palatable to the many ironmongers who have suddenly been metamorphosed into "electrical engineers." At present there are 150 consumers connected, with 4,000 8-c.p. lamps. Gas engines are very largely used for mill work, so that there is room for a good business in the supply of current for motor driving if that branch is energetically pushed. The Council is its own best customer, for the



Suspended Lamp.

Town Hall departments have 350 lights and the theatre another 350, all of 8 c p.

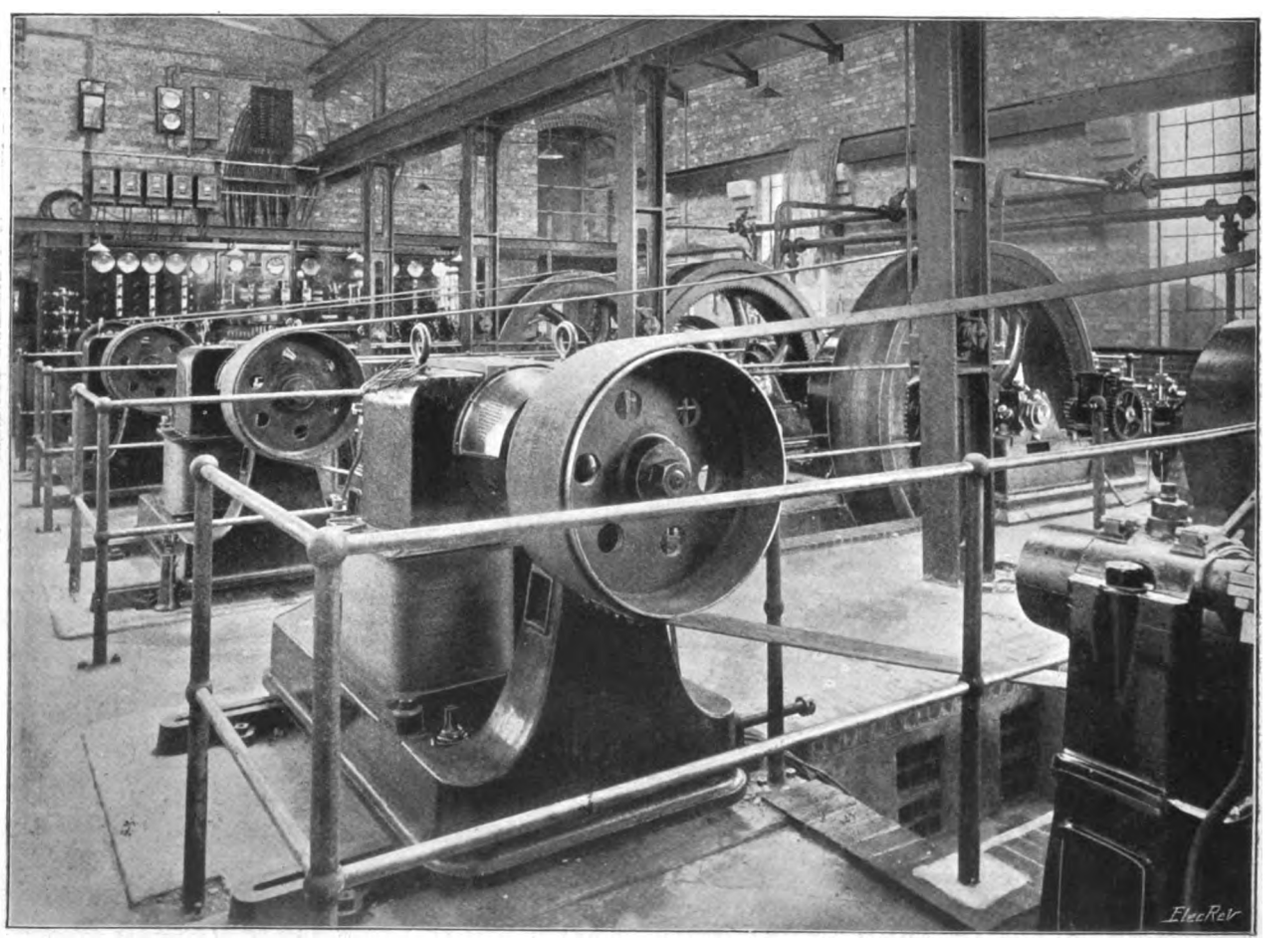
On the occasion of our visit to Lynn, we inspected the wiring and fitting work which had been carried ont by Messrs. Spagnoletti & Crookes at the Town Hall buildings. The various departments are now furnished with very artistic fittings for electric lighting. The Court of Sessions has several wrought-iron electroliers of an exceedingly pleasing design, with nine 16's. In the ballroom a number of very



Bracket.

descents, and the four others have sixteen 5's. The wall fittings bring up the number of electric candles in this room to 140. Messrs. Spagnoletti & Crookes were also the contractors for the wiring of the various other departments here, as well as the theatre already mentioned.

The site of the electricity works is on the ground of the Old Water Works, where there is a convenient siding to the G.E.R. The buildings are engine and dynamo house, with battery room and offices, and the producer house which is situated a few yards away. An idea of the general arrangement of the gas-producer house, gas-holder, scrubbers, &c., can be obtained from one of the exterior photographs accompanying this article.



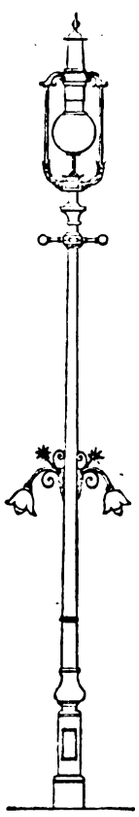
Interior of Station showing Dynamos and Switchboard.

valuable old spider fittings have been converted into electroliers. We give an illustration showing this piece of special work. The centre fitting has 24 candles with 5 c p. incan-

The system of supply is three-wire continuous current distribution at 400 volts pressure, 200 volts on each side of the middle wire. Consumers are supplied at 200 volts.

Digitized by Google

The gas-producer house contains, as will be seen from the picture, plant of the usual type for working with anthracite coal, or coke when necessary. All the gas-producing plant was supplied and installed by Messrs. Fielding & Platt, Limited. There are four sets of gas generators lined with firebrick, set in fireclay and ground cinders. They are fitted with steam jet air injectors, fire bars, cleaning out doors, and feeding hoppers with cover lids. All of the generators are of the same external size, but one has a thicker firebrick lining to reduce the area of the furnace to three-fourths of that of the other three generators. It is, however, so constructed that it can be easily re-lined at a future time to form a full-sized furnace. Each generator (with full-sized furnace) is capable of producing 13,000 cubic



Lamp-post.

feet of gas per hour, of a calorific value of not less than 145 B.Th.U. per cubic foot. Each of these producers is for driving two of the engines in the station. They all feed, as shown, into one common gas-holder, so that the production of gas can be regulated in proportion to the requirements of the station. This ensures fuel economy. The fuel used is anthracite peas, the consumption upon preliminary tests being found to work out at under 1 lb. per I.H.P. per hour. The generators are placed 10 feet apart from centre to centre, and close to the edge of the feeding platform. An iron hood is erected over each producer, with an outlet chimney, and the waste gas pipe discharges under the hood. The gas passes through a series of vertical cast-iron pipes erected outside the producer house, and is cooled by water trickling down the outside of the pipes, with even distribution over the surface. After leaving the cooler the gas passes through a cast-iron hydraulic box fitted with water supply and overflow pipes; it then passes through two scrubbers, one of which is filled with coke and supplied with a water spray and trapped outlet drain, and the other is filled with sawdust. The gas outlet from the sawdust scrubber is provided with a breeches piece and two 6-inch stop valves. In one corner of the producer house there is a small vertical boiler for supplying steam to three generators when working together. It is for delivering 39,000 cubic feet of gas per hour into the gas-holders at a pressure of 1½ inches of water. When required, however, a steam supply will be available from the existing waterworks boilers. The main gas-holder, which was let down before our photo was taken, and therefore does not appear to advantage, is of wrought-iron, 20 feet diameter, with a 10-foot lift. The inlet and main outlet pipes are 12 inches internal diameter, and a 2-inch diameter outlet supplies the ignition burners of the engines. In another view we show an auxiliary gas-holder, 5 feet diameter (with 5 feet lift), which is erected at the extreme end of the gas main, and close to the engine side of the electricity works. The mains from the scrubbers to the main gas-holder are 12 inches diameter, and from there to the auxiliary holder 10 inches diameter. The branches to the engines are 5 inches diameter, and to the generators 6 inches diameter.

Coming now to the interior of the electric generating station, of which we give views taken from either end, there are in position four sets of Fielding & Platt gas engines and General Electric Company's dynamos. The fifth dynamo is on the ground, waiting for its engine. The present night demand requires two of the sets to be running, and a third turning round. The engines consist of the latest designed Fielding patent gas engines, driven by belt direct from the fly-wheel on to the dynamo. Each engine is capable of giving off 100 B.H.P. as a maximum, the ordinary constant working load being 76 B.H.P.

The engines are of exceedingly massive design, specially designed for electric driving. They are fitted with single heavy fly-wheel and outer bearing, the fly-wheel weighing 8 tons, to ensure absolutely steady running. Each engine is fitted with Fielding's patent self-starter and hand turning gear for positioning the engine, enabling one man to start either engine with ease. An improved arrangement of timing cam has been adopted, enabling the point of ignition to be adjusted whilst the engine is running. This is of great importance where varying loads occur.

The dynamos supplied by the General Electric Company, Limited, of London, are of the continuous current shunt-wound type, which can be separately excited off 400-volt mains. They have self-oiling ring bearings. The driving pulley has been proportioned to suit the speed of the engines (150 revolutions per minute). Each dynamo has a normal speed full load output of 40 KW., ranging from 88 amperes at 450 volts to 80 amperes at 500 volts. For battery charging the speed may be exceeded by 10 per cent., and the output may then increase to 80 amperes at 540 volts. The dynamos will be run with separate excitation ordinarily, but upon emergencies they will be run self-exciting, a resistance being provided in the negative lead to the change-over switch to reduce the field circuit pressure by 110 volts.

The accumulator room is arranged in an exceedingly convenient manner. Instead of being arranged in the usual way on tiers, the cells are on two floors, the top one being open through. There are four rows of cells on each floor. There are 225 cells of the well-known Chloride "R" type. The boxes are of glass, and each contains eight positive plates and nine negative plates of the makers' standard size. The specification required that the battery should be capable of discharging at the rate of 40 amperes for 10 hours or 80 amperes for 4 hours without the E.M.F. of any cell falling below 1·85 volts. The cells are mounted upon pitch pine bearers, being insulated from same with the usual glass insulators. The bearers rest upon cross bearers, the latter being insulated from earth by large porcelain insulators. The connections between the regulating cells (which are 38 in number) and the switchboard consist of copper rod so far as the engine room wall, when they are changed to cable by means of a terminal board. This battery is intended for balancing on the three-wire system, and also as a stand-by.

At the Town Hall there is a transformer sub-station, which we illustrate. Here it will be seen that there are two motor transformers (of the Byng-Hawkins type) for balancing the load. The armatures are wound on the same drum with an 80 segment commutator at each end. They are wound for 50 amperes at 200 volts, or 400 volts across the two windings. The normal speed is not less than 1,200 revolutions per minute. The magnets are excited at 400 volts from the outers. The exciting circuit is provided with a fuse and switch arranged to discharge the field through a non-inductive resistance. The leads connecting to the mains have positive main, middle conductor, and negative main switches. The sub-station switchboard, which is seen on the right in our photograph, has two voltmeters, reading up to 250 volts, with fuses in porcelain boxes on the leads connecting to the mains.

Digitized by Google

The main switchboard in the generating station is made up of slate slabs mounted on vertical iron supports fixed by the builder. The rheostat switches are placed on a slate table supported on iron brackets in front of the centre of the board. The switchboard contract as well as the sub-station equipment, the main dynamos, the station lighting, &c., was carried out by the General Electric Company, Limited, who were represented during construction by Mr. W. A. Dyer, A.M.I.E.E.

In the power station there is a 10-ton traveller for the gas engine side, and a 3-ton for the dynamo side, as shown in our interior view.

The system of distribution, as already mentioned, is a three-wire one, with 200 volts on each side, and the mains are fed by two-wire feeders at six different points. The balance is obtained by a third or neutral wire feeder from the sub-station balancing machine at the Town Hall, and two distributing mains, which are run directly into the generating station.

The cables supplied up to the present are as follows:—

·15 sq. in.	Concentric unarmoured feeder ...	1,863 yards.
·1 sq. in.	Concentric unarmoured feeder ...	622 „
·1 sq. in. ·033 sq. in. ·1 sq. in.	Triple concentric unarmoured main...	1,506 „
·15 sq. in.	Concentric armoured feeder	1,281 „
·1 sq. in.	Concentric armoured feeder	472 „
·15 sq. in.	Single (neutral wire) armoured feeder	140 „
·1 sq. in. ·033 sq. in. ·1 sq. in.	Triple concentric armoured main, A size	8,628 „
·05 sq. in. ·025 sq. in. ·05 sq. in.	Triple concentric armoured main, B size	4,242 „

The cables leaving the generating station are two ·15 square inch, and one ·1 square inch unarmoured feeders, and one unarmoured main in a line of six-way Doulton casing, and also a triple concentric main A size, which serves a new district near the dock, and enters the station in the opposite direction from the other cables. The conduit line runs out into the main road where the ·1 square inch feeder divides into two cables, one running as an armoured cable to a point in the Gaywood Road, and the other continuing in the conduit line to a feeding box opposite the railway station. The cables are in all cases carried across the roads in cast-iron pipes, two 4-inch pipes being provided on all conduit lines to allow of extension, and each armoured cable being drawn into a 3-inch cast-iron pipe. The six-way conduits are laid from the generating station to the junction of Blackfriars Road and Norfolk Street, where they are continued in a four-way conduit, one line carrying a ·15 square inch feeder and main being laid down Norfolk Street to the junction of Broad Street and Chapel Street, where the conduits stop, and the feeder divides into two armoured feeders, one branch running to the post office and the other to St. Nicholas Church at corner of Chapel Street. The other four-way conduits are laid down Blackfriars Street past the railway station, where the ·1 square inch feeder is connected into the network, and the conduits are then continued with three-ways, carrying the other ·15 square inch feeder and a distributing main. These run to the junction of London Road, where the conduits stop, and this feeder divides into two armoured cables, one serving the London Road, the other running to the end of High Street in the St. James's Road. The armoured cables are everywhere covered by a creosoted board laid over them to serve as a protection, and as an indication of their existence in the case of further excavation in the streets.

The cables themselves are composed of plain copper conductors, insulated with impregnated fibrous material and lead cased. The unarmoured cables are further protected by a short layer of tarred yarn and thoroughly compounded, and the armoured ones by two layers of steel hooping and tarred yarn as usual.

The insulation resistance measured when laid before service connections were made was 2,000 megs. per mile between either conductor and the other two connected to earth.

The method of making services and the various joint and fuse boxes are all of Prof. Robinson's design, and we hope to give drawings of some of these in our next issue. In order to simplify the making of services on both sides of the system, the polarity of the outermost conductor of the mains is reversed at intervals by means of special boxes, and as the neutral wire is the middle wire the cable connections need only be made on to the outer and neutral, thus obviating the necessity of cutting down to the innermost conductor, and enabling connections to be put on with only one side of the system cut off at the street disconnecting boxes. The middle or neutral is earthed at the generating station.

The public lamps and private services are connected to the mains by means of I.R. braided wire run in wrought-iron tubes, and connected by fuses to the terminals in the service boxes.

The incandescent lamps for street lighting are placed in specially-designed ornamental lanterns on posts in streets where the paving or roads are sufficiently wide, and supported on wall brackets or on suspension wires where the streets or footways are too narrow to allow of posts being used. For the lighting of "The Walks" a special double arm standard is used, as will be seen from one of our sketches; while for cross corners here some of the standards have four arms. The lamps are run off the distributing mains in parallel, and 200-volt lamps are used throughout. In the more important thoroughfares and corners arc lamps are to be placed, and these are either open arcs run four in series on the 200-volt mains, or enclosed arcs run two in series on the same voltage. Eight of the lamps are of Siemens's "Band" (5-ampere) type, and eight (7-ampere enclosed) are by the Davy Company. The arc lamp standards also carry two 16-c.p. incandescents. The lamps are controlled from the base of the lamp-posts. The arrangement is such that the lamp-lighter's occupation is not gone.

In High Street, which is a narrow and busy street, the lighting is to be effected by means of lamps suspended on ornamental wrought-iron arches carried on the walls of the buildings on opposite sides of the street.

The whole of the work connected with the mains and conduits and street lighting is being carried out by Messrs. Siemens Brothers & Co., with the exception of the lamp-posts, brackets and arches, which have been purchased direct from the founders (Messrs. Law, of Glasgow). The street lighting extensions which have been arranged for since the original contracts were placed, are also being carried out by Messrs. Siemens.

The following is a list of the contractors:—

Buildings	Messrs. Merredew & Wort, Stevenage.
Gas producing plant and gas engines.	Messrs. Fielding & Platt, Limited, Gloucester.
Dynamos, switchboards (main and sub-station), &c.	General Electric Company, Limited.
Accumulators	Chloride Electrical Storage Syndicate.
Public lamps, lanterns and main work.	Messrs. Siemens Bros. & Co.
Lamp-posts, brackets and arches for public lighting.	Messrs. J. & A. Law, Glasgow.
Meters...	Long-Schattner.
Arc Lamps	Messrs. Siemens and the Davy Company.
Stoneware conduits	Messrs. Doulton & Co.

It would not be fitting for us to bring this article to a close without acknowledging our indebtedness to the consulting engineer, Prof. Henry Robinson, and to some of the contractors who have taken part in the Lynn installation. To Mr. Leigh Robinson, son of the consultant, who has been on the spot for the past 11 or 12 months controlling the carrying out of the work, we especially owe a debt of gratitude for placing at our disposal certain material for the compilation of our description, and also for the kindly and courteous way in which he placed himself at the service of our representative on the occasion of a recent visit.

The resident electrical engineer, appointed about five months ago, is Mr. J. Pilling, and Mr. Williams has been appointed assistant.

Change of Name.—We note that our esteemed contemporary, the *Railway World*, has changed its name to the *Tramway and Railway World*. This is not to denote any alteration in the policy of conducting the paper, as our contemporary has always been, what we regard over here, more of a tramway journal than anything else.

The Telegraphic Wire Export Trade.—The past month proved to be a relatively quiet one as regards the export trade of this country in telegraphic wire and apparatus connected therewith. The returns just issued for August show that the value of the shipments only amounted to £87,517 as compared with £97,635 in the preceding month, and no less than £265,501 in August, 1898. Earlier in the year, 1899 gave promise of seeing record figures set down, but the quietness of the past few months has put the total behind that of last year, the value of the exports during the eight months ending with August last having reached a total of only £686,825, which compares with £811,997 in the corresponding period of last year, and with £700,748 in the first eight months of 1897.

Wireless Telegraphy.—According to the *Review of the River Plate* a representative of the Wireless Telegraph and Signal Company, of London, has been establishing the Marconi patent in River Plate and other South American countries. A set of apparatus has been at work in Buenos Ayres recently.

CONTRACTS OPEN AND CLOSED.

OPEN.

Barking Town.—October 24th. The District Council wants tenders for boilers, pipe work, two 100-kw. steam dynamos, switchboard, motor and trailer cars, trucks and electrical equipment, overhead equipment, underground feeders, conduits, road work, &c., for the Barking and Beckton light railways. See "Official Notices" September 1st.

Barnsley.—September 16th. Tenders are wanted for electric light wiring and fittings at the Harvey Institute, Eldon Street, for about 700 lights. See "Official Notices" August 18th.

Belfast.—September 31st. The Electric Committee wants tenders for c.i. floor plates and w.i. rails for the electric light department. Specifications from the city electrical engineer on payment of one guinea, returnable as usual.

Birkenhead.—September 29th. The Corporation wants tenders for boosters, switchboard, accumulators, cables, and laying same. See "Official Notices" this week.

Blackburn.—September 20th. The Corporation wants tenders for 40 electric cars and two 256-kw. steam dynamos. See "Official Notices" September 8th.

Cardiff.—September 27th. The Corporation wants tenders for cast-iron arc lamp-posts. See "Official Notices" this week.

Carlisle.—September 18th. The Corporation wants tenders for extension of switchboard for dynamos 5 and 6, and for traction work. See "Official Notices" September 1st.

Darwen.—September 25th. The Corporation wants tenders for a high speed vertical engine and dynamo (300 to 350 kw.); also switch work. See "Official Notices" September 8th.

Germany.—September 20th. Tenders are being invited until September 20th by the Cotton Wool Exchange authorities in Bremen for a complete installation of electric lighting in the new Exchange. Tenders are to be sent to Das Banbureau für die Bremer Baumvoll börse la Dechanatstrasse, Bremen, whence particulars may be obtained.

Germany.—October 16th. Tenders are being invited by the municipal lighting and tramway authorities of Königsberg, Prussia, until October 16th, for the supply of six boilers required in connection with the extension of the electric power station, to supply steam to new engines aggregating 1,800 e.h.p. Tenders to be sent to Die Direction der Städt, Belenchtungswerke und der Electr. Strassenbahnen Kaiserstrasse 41, Königsberg, Prussia, whence particulars may be obtained for 1s.

Glasgow.—October 10th. In connection with the tramway scheme the Corporation wants tenders for switchboards, fuel economisers, two 50 and one 30-ton electric travellers, power station steel work, and cables. See "Official Notices" September 8th.

Heckmondwike.—September 20th. The District Council wants tenders for the supply of water-tube boilers, economiser, pipe work, steam dynamos and motor boosters, accumulators, switchboard work, travelling crane, mains, arc lamps and posts, and station lighting. See "Official Notices" August 25th.

Huddersfield.—October 2nd. The Corporation wants tenders for five Lancashire boilers. See "Official Notices."

Ilfracombe.—September 25th. The District Council wants tenders for boiler plant, engine plant, dynamos, condensers, switchboard, mains, lamp-posts, accumulators, meters, crane, buildings, &c. See "Official Notices", August 18th.

Luton.—September 22nd. The Council wants tenders for boilers, superheaters, engines, dynamos, switchboard, steam and other piping, batteries, street conduits, boxes, feeders, arc lamps and posts, and various other plant and machinery for the electric lighting installation. See "Official Notices" August 25th.

Middleton.—September 20th. The Corporation wants tenders for Lancashire boilers, superheaters, economisers, steam pumps, condensers, steam dynamos, balancer and boosters, switchboard, accumulators, cables, crane, &c., for electricity works. See "Official Notices" September 1st.

Oldham.—The Electric Light Committee invites tenders for rolled steel girders, concreting, and other works required in the foundations for "Klein's Tower Water Cooler" at the electric light station, Gas Street, Oldham.

Rotherham.—October 9th. The Corporation wants tenders for Lancashire boilers, engines, dynamos, piping, condenser, economiser, battery, switchboard and boosters, feeders, mains, road work, &c., for electric lighting. For particulars see "Official Notices" September 8th.

Runcorn.—September 27th. The Urban Council is inviting offers for the electric lighting of the district, to be sent to the chairman of the Highways Committee.

Russia.—The municipal authorities of Perm are at present inviting tenders for the concession for the establishment and exploitation of a central electric lighting station in the town.

Salford.—September 28th. The Corporation wants tenders for 16 Lancashire boilers and superheaters. See "Official Notices."

Sculcoates Union.—September 21st. The Guardians want tenders for the installation of electric lighting and telephones at the Workhouse. See "Official Notices."

South Wales.—September 28th. The proprietors of Margam Copper Works, Port Talbot, wants tenders for the electric lighting (arc and incandescent) of their works. See "Official Notices" September 8th.

Sunderland.—The Corporation wants tenders for four 270-kw. three-crank direct current steam dynamos, and two surface condensers and cooling tower. See "Official Notices" August 18th.

Sydney (N.S.W.).—November 3rd. The Municipal Council of Sydney is inviting tenders for the construction and erection of a refuse destructor for treating 60 tons of refuse per day (24 hours).

Warrington.—September 30th. The Committee of Visitors of the Winwick Asylum, near Warrington, invite tenders for Contract No. 1.—Generating plant, including three sets of condensing engines or turbines, with directly coupled dynamos, each of 100 kw. output at 220 volts, booster set, motors, surface condensers, cooling tower, steam and exhaust pipes, &c. Contract No. 2.—Switchboard. The drawings can be inspected and specifications obtained of J. P. Muspratt, Clerk to the Committee of Visitors, County Offices, Preston, on payment of £2 2s for each specification, returnable. A separate tender must be sent in for the work included in each specification. See "Official Notices" September 8th.

CLOSED.

Bexhill.—The Council has approved the acceptance of the tender of £3,600 by Mr. Minter, for the erection of electricity works buildings.

Colwyn Bay.—At a special meeting of the Council held last week the tenders of Mr. Bertram Thomas, of Manchester, for carrying out the electric lighting of the town to the specification of Messrs. Lacey, Clirehugh & Sillar were accepted.

Glasgow.—An exchange says that the following tenders have been accepted in connection with the equipment of the electric tramway power station for the Corporation: Mirrlees, Watson, and Yaryan Company, Glasgow, surface condensers and air pumps, £15,000; Mavor & Coulson, Glasgow, centrifugal circulating pumps; G. and J. Weir, Glasgow, boiler feed pumps.

Digitized by Google

Grimsby.—The Town Council has confirmed the acceptance of the following tenders for electric lighting plant and machinery:—

Boilers.—Messrs. A. Anderton & Sons, Accrington	£1,875
Engines, Dynamos, &c.—Messrs. Mather & Platt, Limited, Salford Iron Works, Manchester (this to include series windings)	12,510
Battery.—The Tudor Accumulator Company, Limited, London	850
For maintenance	54
Switchboard.—Messrs. James White, Limited, Glasgow	1,350
Mains.—The British Insulated Wire Company, Prescot	14,967
Total	£31,606

There was some discussion as to the reason of the original estimate being exceeded, but after explanations as to additional machinery and buildings the minutes were adopted.

Halifax.—The Council has confirmed the acceptance of the following tender:—Messrs. Belliss and the Electric Construction Company, Limited, for the supply of three 1,200-H.P. engines and 750-KW. generators for £7,419 each.

Leeds.—The City Council has accepted the tender of Mr. E. C. Wallis for an electric light installation (£462) for the wholesale meat market.

Leeds.—The Tramways Committee has accepted the tender of Mr. T. Harding Churton for the electric lighting of the car sheds, for the sum of £1,170.

Wigan.—The Council has accepted the tender of Mr. W. Winnard, of Wigan, for the erection of electricity works buildings at £15,789. The highest tender was £16,289.

THE LONDON COUNTY COUNCIL AND ELECTRICITY.

The Highways Committee of the London County Council has just issued a very lengthy report of its proceedings for the year ended March 31st, 1899. On the question of tramways, it says that by the London United Tramways Bill it was proposed, among other things, to repeal Sections 17 to 28 of the London United Tramways Order, 1895, relative to the use of mechanical power, and it was also proposed to authorise the use of electrical traction upon the whole of the company's system, which extends not only within but outside the County of London, and for this purpose, among other things, to place poles to carry wires over the streets. The Council, while it has not offered objection to the use of the conduit system of electrical traction, has consistently refused consent to the introduction into any part of the county of the overhead system. As the undertakers were not prepared to accept the terms of the Council, the Council decided to oppose the introduction of the Bill, and the company, in order that the measure might be allowed to proceed, withdrew from it all proposals for the construction of new tramways within the county.

On the subject of the electric meter-testing station, the Committee says the amount of energy supplied to any consumer is, unless otherwise agreed, to be ascertained by means of an appropriate meter, which must be of a construction and pattern approved by the Board of Trade, and must be certified to be so, and to be a correct meter and properly connected with a service line, by an inspector appointed by the Council. This is the case with regard to most of the electric lighting orders under which energy is supplied in London. It does not apply, however, in the cases of the St. Pancras (Middlesex) Electric Lighting Order, 1883, and the St. Luke's, Chelsea, Electric Lighting Order, 1891, under which application has to be made to a court of summary jurisdiction to appoint an inspector to settle any dispute. This has been the cause of some inconvenience to consumers in the past, although in some cases the Council's inspectors have, by consent of both parties, adjudicated upon disputes arising outside its area of jurisdiction. For the purpose of meter-testing the Council maintains a testing station, with the necessary appliances for testing meters of all patterns up to a capacity of 600 amperes, at Nos. 42 and 43, Cranbourne Street; and qualified inspectors are engaged there in testing meters. In 1887 the Board of Trade intimated its approval of two patterns of meters, viz., the Ferranti meter and the Hookham meter for continuous current, and in 1899 the self-winding Aron meter for continuous and alternating current; and these, with the Shallenberger meter for alternating current, are the only meters approved by the Board of Trade. The Council has adopted rules and scales of fees with regard to the testing of electricity meters and to other services under the Electric Lighting Acts and orders, and these rules and fees have been approved by the Board of Trade. The Council's officers have for many months been engaged, in conjunction with the officers of the Board of Trade, in the examination of various meters, and the noting of their performance under ordinary working conditions. Thirty-six meters have been under observation for this purpose, and these have been tested at Cranbourne Street before being fixed at consumers' premises. During the year 279 meters of various patterns, the accuracy of which was in dispute, have been tested at the station, and all of these have also been examined at the consumers' premises; 444 meters have been tested for electric supply companies and found to be correct, and sealed accordingly; and 368 tests have been made for meter manufacturers. The amount of the fees received during the year 1898-9 was £387 3s. 5d. This sum does not, however, include anything for the Board of Trade meter-tests, for which no charge is made.

The Council has, since the date of the last annual report, received and dealt with about 290 notices, some of which referred to works extending over large areas; and each of these notices has been separately considered, and, in nearly all cases, special conditions have been attached to the Council's consent. The Council has, during the year, sanctioned the laying of mains in about 132 miles of streets and roads, in addition to a very large number of service lines to consumers' premises. Of these mains, those in 55 miles of streets were for currents of high tension, and in 77 miles for those of low tension. The Council has in all cases required that the mains should be laid under the footways wherever it was found practicable to do so, and that the covers of the street boxes should consist of iron frames filled in with material to suit the paving. The Council also requires that where high-tension mains other than concentric cables are used, each of the street boxes shall be provided with an inner as well as an outer cover, the two being insulated from each other as far as practicable, the outer cover being efficiently connected to earth, and that adequate precautions shall be taken to prevent the accumulation of gas in the boxes and conduits, and any risk of accident through defective insulation of mains.

An official is employed to inspect the works of the companies in the public streets, in order to see that the requirements of the Council are complied with.

As stated in previous reports, a system of supply has been adopted under some electric lighting orders, which involves the construction of transformer boxes or converting stations of very large dimensions to be placed under the public thoroughfares. The Council has, during this year, again taken exception to proposals for the appropriation of large portions of the space under the streets for this purpose, there being, in its opinion, no necessity for such appropriation, as the requisite provision might be made upon private ground. The Board of Trade has, however, as in former cases, overruled the Council's objections, and the Council has, in consequence, when dealing with applications of this nature, given its consent upon the conditions laid down by the Board of Trade in deciding on the cases submitted to it on appeal by the companies concerned.

The Council requires that, in connection with any notices for the construction of transformer boxes, full particulars and plans shall be supplied, showing the exact position to be occupied by, and the internal and external dimensions of, each of the boxes proposed to be constructed, and also the existing works which will be disturbed thereby.

The Council was empowered by its General Powers Act, 1893, to establish an installation for the electric lighting of the Victoria Embankment and the Westminster and Waterloo Bridges. Since the passing of the Act the Charing Cross and Strand Electricity Supply Corporation has obtained permission to lay its mains across Waterloo Bridge, upon condition that the corporation do supply light to the lamps of the bridge and maintain them free of cost, and the terms of this arrangement have been embodied in an agreement prepared by the solicitor. Provision for the lighting of Waterloo Bridge having thus been made, it was necessary to provide only an installation for the other bridge and the Embankment.

The Council has adopted a scheme in which provision is made for 144 arc lamps, to be distributed as follows:—

Victoria Embankment, &c.:—

On the kerb of the carriageway (land side)	28	
" " " (river side)... ...	29	
" parapet wall	64	
" Northumberland Avenue approach, &c. ...	8	
	—	129
Piers adjacent to the Embankment		5
Westminster Bridge and approaches		10
		144

The lamps on each side of the carriageway of the Embankment are to be about 240 feet from each other, and those on the parapet wall about 66 feet apart, while those on Westminster Bridge and Northumberland Avenue approach will be placed at convenient distances. The whole of the parapet lamps and the alternate lamps on each kerb of the Embankment, and also some of the lamps on Westminster Bridge, will be extinguished at midnight, thus decreasing to an appreciable extent the cost of maintenance. It may be mentioned that the parapet gas lights now in use are extinguished at midnight, so that what is proposed would in this respect be no departure from the present practice.

As regards the plant, it may be stated that by the provision of forced draught the necessity for a chimney at the generating station will be avoided; and that, should the Council at any time decide to light all or any of its subways by electricity, the machinery would be sufficient for the purpose.

The capital expenditure for the installation, according to the estimate submitted to the Council, will probably be about £25,300, made up as follows:—

Buildings	£6,900
Boilers and machinery	9,600
Mains	4,200
Lamps, standards, &c.	4,300
Salaries	300
	£25,300

The probable annual cost of maintenance is estimated at £3,509, made up as shown below, the amount of the capital charges being calculated on the repayment of capital cost being spread over a period of 42 years, the length of time allowed by the Council for repayment of loans to London local authorities for similar works:—

Digitized by Google

Maintenance	£2,387
Rates and taxes	110
Capital charges	1,012
	£3,509

The Council has accepted the tender of Messrs. McClure & Whitfield, amounting to £3,726 5s., for the supply of the dynamos, and of Messrs. J. E. H. Andrew & Co., amounting to £2,100, for the supply of gas engines, required in connection with the installation, and these portions of the work will shortly be proceeded with.

NOTES.

The Scarcity of Paraffin Wax.—The prevailing scarcity of paraffin wax seems likely to become a matter of some seriousness to the makers of electrical conductors in this country. The importance is all the greater in view of the rapidly increasing demand for this product, the requirements now amounting to double the available supply. About one-half the supply of oil coming to this country is Russian and the other half American and Rangoon, but as paraffin wax cannot be obtained from Russian oil, one has to look for a remedy for the present situation by endeavouring to cultivate the importation of American wax to this country. We are not aware what may be the difficulties, if any, standing in the way of such a development, but we should think it would be worth the while of American traders to give the matter attention.

Charterhouse Science and Technical Schools and Rogers' Memorial Institute.—The winter session of this, one of the largest and oldest science schools in the United Kingdom, will commence on Saturday, September 23rd, 1899, under the presidency of the Rev. H. Swann, M.A. During the late session a large number of students availed themselves of the privileges afforded by this institution, and of these (who were mostly elementary teachers) the majority presented themselves for examination. Instruction of a practical character is given in most of the sciences at a very nominal fee. Those who have leisure can attend, at a very moderate charge, the day science classes. Day classes will also be held to prepare candidates for matriculation (London), clerical, medical (including dental), legal, and other examinations. Students who aim at becoming proficient in physics and chemistry have the opportunity of working in well-fitted laboratories. During the session artizans, apprentices, improvers and others will have the privilege of attending the London County Council technical classes. Full particulars of the classes may be obtained from C. Smith, organising secretary. Those interested in education will rejoice to learn that the work commenced by the late Rev. W. Rogers, M.A., and ably continued by the late Rev. John Rodgers (formerly vice-chairman of the London school) is so vigorously continued by the present president and committee.

Steinmetz, of the General Electric Company of America.—The name Steinmetz is one that future generations will have cause to remember on account of his brilliant experimental work in electrical science. He is of German birth, and was educated partly in Germany and partly at the Zurich Polytechnic. When quite a young man he was exiled from the Fatherland on account of Anarchistic writings, but his ideas on social relations and government have been considerably modified since then. Steinmetz is always smoking, and there is a characteristic story to the effect that when the directors issued a regulation prohibiting smoking in the Schenectady works, he wrote them that if such a bye-law was enforced he should stay at home. Needless to say, an exception was made in his case. The subject of our sketch is a cripple, but rides a specially made bicycle, which enables him to pursue his studies out of doors in natural history and mineralogy.

Another Strike!—An American exchange says it is reported that the "punkah pullers" in West Borneo are in revolt because the Rajah of Koti has bought $30,000 worth of electric fans, and the coolies who formerly worked fans, or punkahs, by hand, will now be out of a job.

Commemoration at Como of the Discovery of the Voltaic Pile.—The recent fire at the Como Exhibition, which destroyed many of the relics of Volta, is not to be allowed to stop the celebration of the centenary of the discovery of the battery. Another exhibition has been organised, and a Congress of electricians is to be held at Como during the current month to read and listen to papers on electrical matters, and to do honour to Volta. We have received a circular giving information about the arrangements. The Congress has been organised by two societies acting conjointly, the Associazione Elettrotechnica Italiana, and the Societa Italiana di Fisica. It is to be opened on September 18th by Prof. Augusto Righi, of Bologna, with an address commemorative of Volta, and will last a week. Papers are to be read, and there will be dinners, *fêtes*, a reception, visits to the tomb of Volta, and to neighbouring electrical installations. A competition in electrical science for a prize of L.3,000, presented by gentlemen of Como, is to be arranged by the committee, but the details are not announced. The principal papers to be read are the following:—

Prof. P. Blaserna.—"On the Disturbances produced in Galvanometers by Electric Tramways."
" " "On the Secular Variations of the Magnetic Inclination in Ancient Times."
Prof. S. P. Thompson.—"Magnetic Images and their Application to the Theory of Motors with Revolving Fields."
Prof. G. Grassi.—"Studies and Experiments on the Transformation of Triphase into Monophase Currents."
Signor G. Semenza.—"The Practice of Electrical Transmission at High Voltage."
Profs L. Donati and G. Grassi will introduce a discussion on electrical terminology.

The president of the Executive Council is Prof. Giuseppe Colombo, the vice-presidents are Prof. P. Blaserna and Prof. G. B. Cadenazzi, and the secretary is Signor Alessandro Panzaresa. The address of the committee is Via S. Paolo, 10. Milan. The general programme is as follows:—

September 18th	10 p.m.	Inauguration of the Congress. Commemoration of Alessandro Volta by Prof. Augusto Righi.
"	7 0 p.m.	Dinner given by the members of the Congress to foreign electricians and other distinguished persons.
" 19th.	9 0 a.m.	General sessions of the Congress.
"	2 0 p.m.	" " "
" 20th.		*Fête* on the Lake given by the city of Como.
"	9.0 p.m.	Grand Venetian illumination of the city of Como, arranged by the Executive Committee of the Exhibition in honour of the electricians.
" 21st.	9.0 a.m.	Meeting of the two organising societies.
	2 0 p.m.	" " "
"	7.0 p.m.	Dinner given by the Prefect of Como, Comm. Felice Segrè.
" 22nd.	Morning.	Visit to the tomb of Volta.
"	2 0 p.m.	Meeting of the two organising societies.
" 23rd.	9.0 a.m.	" " "
"	2.0 p.m.	General session and close of the Congress.
"	9.0 p.m.	Reception and Concert at the Casino.
" 25th, 26th.		Excursions to the electrical works at Paderno, Milan, and Vizzola.

Sir W. H. Preece's Wireless Telephony.—It is stated by the *Carnarvon and Denbigh Herald* that for some weeks past experiments of great interest in wireless telephony have been carried on by Sir W. H. Preece near Carnarvon. As a matter of fact it is telegraphy, not telephony, which Sir W. H. Preece has been working on, telegraphy on what may be called the "buzz r" Morse system, a telephone being used as a receiver. All the London papers have naturally fallen into the same error as is their wont.

A Large Electric Traveller.—Our New York namesake says that the largest electric travelling crane ever designed is to be built in Milwaukee, Wis., for a leading Philadelphia plant. It will be of 150 tons capacity. There are other 150-ton cranes, using 75-ton trolleys, but this crane will have one 150-ton main trolley, with a test load of 200 tons, and an auxiliary trolley of 25 tons capacity.

The British Association.—The Dover meeting, although not the smallest by two or three, promises to be exceedingly small in numbers, for up to Wednesday night only 1,216 names were registered. In Section A the proceedings yesterday, after the presidential address, should have been papers by Dr. Bauer, on "Recent Magnetic Work in North America," and the presentation of a report on the "Methods of Determining Magnetic Force at Sea," but the paper was not read nor the report presented. The Sectional Addresses were well received, especially Sir W. White's on "Steamships." Sir E. Carbutt and Sir W. H. Preece proposed votes of thanks. In the physiology section a report on the "Electrical Changes Accompanying the Discharge of the Respiratory Centre," was read. In the chemistry section, Prof. Dewar read a paper on the "Solidification of Hydrogen."

Brighton System.—The following comes to hand as we go to press:—"Will you kindly give me a simple explanation of the system of charging for current known as *the Brighton system?* Also an illustration of, say, 20 16-c.p. lamps burning an average of four hours per night. I shall esteem your answer a great favour, as I have asked so many times and always got different answers.—Yours truly, CURRENT."

[We refer our correspondent to an article on this subject in our issue of November 6th, 1896, p. 595.—EDS. ELEC. REV.]

Appointments Vacant.—The Watford Council wants a junior assistant engineer. See "Official Notices" this week.

The York Electric Lighting Committee wants an assistant electrical engineer and other members of the staff for the electric lighting works. See "Official Notices" this week.

The Corporation of Newport (Mon.) wants an electrical engineer with experience in alternating current stations, at a salary of £2 per week; also a mains superintendent with a thorough knowledge of sub-stations, transformers, &c. See our "Official Notices."

Two assistants are required in the electrical engineering department of the Central Technical College, City and Guilds of London Institute. Salary, £100 per annum. See our "Official Notices."

The Institution of Electrical Engineers' Reunion in Switzerland.—On Wednesday last week the first annual summer meeting of the Institution was held at the Polytechnikum, and was followed by a lunch given to the Swiss Association and other friends at the Tonhalle. In the afternoon the Polytechnikum was visited; the party afterwards proceeded to Lucerne. On Thursday most of the members travelled by the Stansstad-Engelberg Electric Railway to Engelberg, and then went on to Interlaken, *viâ* the Brünig Pass, one of the most interesting and enjoyable experiences of the tour. The Jungfrau Electric Railway was inspected on the following day, amid magnificent surroundings, and on Saturday the tour concluded with a visit to the Burgdorf-Thun Electric Railway. Many of the visitors remained in the neighbourhood of Interlaken, to rest after their exertions; others went to Como, some to Paris, but the majority returned home on Saturday and Sunday. It was agreed on all hands that the tour had been most successful, and it is highly probable that a similar excursion will be made next year, in response to Dr. Rathenau's generous invitation, to the works of the Allgemeine Elektrizitäts Gesellschaft, at Berlin, and to other places of interest in that district. We hope to give our readers a full account of the whole of the proceedings in future issues.

Accident to the P.O. Pneumatic Tubes.—Hundreds of important telegrams were delayed at St. Martin's-le-Grand one day towards the end of last week. A number of carriers became blocked in one of the tubes. It was about five hours, says the *Daily Mail*, before the telegrams were released and sent on their way.

Electrical Resistance of Human Blood.—In a recent communication to *Nature*, Dr Dawson Turner says that it is not easy to measure the electrical resistance of the blood of a living person. His best results were obtained by placing five cubic millimetres of freshly drawn blood between two cup-shaped electrodes three millimetres in diameter, coated with spongy platinum, and fixed ·75 millimetre apart. He says that the average resistance of normal blood at 60° Fahr. measured by Kohlrausch's method is 550 ohms; but an observation which may be of great value to the physician is appended: "A striking change may be observed in pernicious anæmia, the resistance in this disease being sometimes diminished to about one-half that of normal blood. It is suggested that the blood contains an abnormal amount of salts.

"Welcome, Dewey!"—When Admiral Dewey arrives at New York Harbour on September 28th, he will find the place rich in electrical illuminations in honour of his return. We read in a New York exchange that the displays will exceed anything ever before seen in New York. The great span between New York and Brooklyn will shine out a "Welcome, Dewey," in letters 36 feet high. The legend will be 300 feet long, and more than 8,000 high c.p. incandescent lamps will be used in it. There are to be "Welcome" legends on a smaller scale, and other electrical illuminations everywhere.

Electric Locomotives for Japan.—The *Engineer* says that two electric locomotives have recently been supplied, by an American firm, to the Japanese Government. They will be used in coal mines. Their height from the rail, exclusive of the trolley, is 2 feet 10 inches; width, 4 feet 2 inches; and length over buffers, 11 feet 8 inches. Each locomotive complete weighs 12,050 lbs., and is of 20 H.P., to run at a speed of 8 miles an hour.

NEW COMPANY REGISTERED.

Pulford Brothers, Limited (63,544).—This company was registered on September 8th, with a capital of £3,000 in £1 shares, to acquire and take over as a going concern the business of an electrical engineer, now carried on by Egerton G. Pulford at Moorfields and Brooks Alley, in the City of Liverpool, and to carry on the business of manufacturers of and dealers in electric lamps, electricity meters, electrical switches, cut-outs, and all kinds of apparatus, machinery and appliances, capable of being used in connection with the generation, storage and utilisation of electricity or other force; cycle and carriage makers, ironfounders, saddlers, platers, japanners, annealers, galvanisers, &c. The first subscribers (each with one share) are:—Egerton G. Pulford, 15, Moorfields, Liverpool, electrical engineer; John Macleod, 41, Upton Road, Birkenhead, engineer; John Macleod, 41, Upton Road, Birkenhead, manager; Miss Mary C. Macleod, 41, Upton Road, Birkenhead; Miss Maggie S. Macleod, 41, Upton Road, Birkenhead; John H. Buyer, Exchange Chambers, Bixteth Street, Liverpool, warehouse owner; Daniel Higson, 36, Dale Street, Liverpool, solicitor; and Mrs. Elizabeth Pulford, 34, Grove Road, Rock Ferry. The number of directors is not to be less than two nor more than five; the first are Egerton G. Pulford and John Macleod, jun.; qualification, 250 shares; remuneration as fixed by the company.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Greenwood and Batley, Limited (27,098).—This company's annual return was filed on July 24th, when 11,066 preference and 18,052 ordinary shares were taken up out of a capital of £400,000, in 14,000 preference and 26,000 ordinary shares, all of £10 each; £10 has been called on each of 6,934 preference and 12,134 ordinary shares, and £3 on each of 1,466 preference and 1,252 ordinary, resulting in the receipt of £198,834; £73,320 is considered as paid up on 2,666 preference and 4,666 ordinary shares.

Globe Telegraph and Trust Company, Limited (7,465 C).—This company's annual return was filed on August 18th, when 180,042 preference and 180,227 ordinary shares were taken up out of a nominal capital of £5,000,000 in 250,000 preference and 250,000 ordinary shares of £10 each. £10 per share has been called up, and £3,602,690 has been paid.

CITY NOTES.

Huddersfield Corporation Electricity Works Accounts.

Last year, when dealing with the Huddersfield accounts, we referred to the steady and sound progress shown by the results of the working of the business up to the end of the year 1897. We are glad to see that the surplus of 1897 was more than doubled in 1898, and it may be noted that the "surplus" for last year is very nearly the same as the loss for the first year, 1893. The items in the "Costs" show small decreases, with the exception of "Oil, waste, &c.," the total decrease in costs amounting to as much as ½d. per unit, the increased production or output being over 150,000 units. The total cost per unit has now been reduced to just below 2d.

The following statement shows the general position of the undertaking:—

	1897.	1898.	Increase.
Total capital expenditure	£69,415	£93,494	£24,079
Number of units sold	438,848	593,377	154,529
Number of lamps connected	41,702	54,154	12,450
Gross revenue	£9,060	£11,866	£2,806
Gross profit	£4,964	£6,936	£1,972
Average price per unit sold	4·66d.	4·51d.	—0·15d.

Revenue Statement.

	1897. Gross.	1897. Per unit.	1898. Gross.	1898. Per unit.	Increase.
Sale of current	£8,533	4·66d.	£11,158	4·51d.	—0·15d.
Meter rents	458	0·25d.	630	0·25d.	...
Supply of lamps	...	...	83	0·04d.	+0·04d.
Sundry fees, &c.	69	0·04d.	...	...	—0·04d.
Gross revenue	£9,060	4·95d.	£11,866	4·80d.	—0·15d.

Cost of Production.

	1897. Gross.	1897. Per unit.	1898. Gross.	1898. Per unit.	Increase.
Coal	£901	·49d.	£1,170	·47d.	— 02d.
Oil, waste, &c.	104	·06d.	161	·07d.	+ 01d.

The Brush Electrical Engineering Company, Limited.

The tenth annual general meeting of the shareholders of this company was held on Friday, September 8th, at the Cannon Street Hotel, Mr. J. B. Braithwaite, jun., M.I.E.E., presiding.

The Chairman, in proposing the adoption of the report, said that dealing first with the profit and loss account, which interested the shareholders most, they would see that the company had earned in gross profit £4,392 more than the previous year. Their earnings had been £54,039, against £49,647, and what was very satisfactory was that they had been able to retain the whole, or rather more than the whole, of that increase as net profit. The net profit showed an increase of £4,942. So that, broadly speaking, they might say that the additional profit had been earned without any increase of expenditure. That, he thought, was a very satisfactory thing, and one that they had to congratulate themselves upon last year. If they would look at the various items of expenditure they would see that the total general charges this year were £11,780 18s. 1d. against £11,276 9s. 9d., showing an increase of £500 only, and that £500 was the additional directors' fees, which, as they mentioned last year, they proposed to take, now that the company was earning a dividend on the ordinary stock. They were entitled under the articles to take £2,000, but they did not intend to exercise that right to the full. On the maintenance of buildings and plant they had spent £4,438—rather more than last year—but they must always keep their buildings and plant in first-rate condition, and whatever money they required for that purpose must come out of the revenue. The maintenance of patents had cost them £672, and the sum of £5,625, interest on first debenture stock, was the same as last year. There was £2,425 for interest on the second debenture stock, and an item of £611, being the remainder of the cost of redeeming that stock, which was now extinguished. That left them a balance of £31,880 as against £26,938, showing an increase of just on £5,000. They really had another £1,000 beyond that, because last year they put aside £1,000 out of profits to provide the nucleus for an insurance fund in connection with the Workmen's Compensation Act, and as that sum was not required this year, they really had £5,942 more to distribute. They proposed to deal with that money in the following manner:—Extra dividend to the ordinary shareholders, £3,600, raising their dividend to 5 per cent. for the year. Then, under their profit-sharing scheme, their workmen's bonus fund would require an additional £360, and they proposed to raise their carry-forward to over £5,000. Turning to the balance-sheet they would find some very considerable changes there, due to the rapid extension of their works at Loughborough. On the credit side they would see that, as he intimated to them last year, they had spent a very considerable sum on additions to their plant and machinery—no less than £55,956 during the year, and he told them that over and above that sum, they had been obliged to incur additional liabilities. The fact was that at the present time their business was increasing by leaps and bounds, and it was quite impossible to keep pace with the increase by any extensions they might make at the works. He told them last year that they contemplated the erection of a new car shop. They had pushed on with the erection of that building as fast as possible, for they had orders in hand before the shop was finished, and although it was capable of turning out 250 additional electric cars per annum, they had more orders now than they could turn out. The only consolation they had was that all their competitors were in the same boat, owing to the very rapid increase in the use of electric cars in this country. Taking the next item—stock, that had risen to the extent of £31,926. That, of course, they would expect, and it showed that they had not been extending their works without a *raison d'être*, and if they extended the works still further they must expect that item still further to increase. The debtors had increased by £10,820, which was the natural sequence to the increased trade they were doing. Turning to the debtor side of the balance-sheet, they would see that the capital remained the same. The creditors showed some increase, due to the increase in the business, and corresponding somewhat to the increase of debtors on the other side. The depreciation and reserve fund stood at £10,000, which would be increased to £15,000 after that meeting. The Workmen's Compensation Act insurance fund stood at £1,000, and he might say that the experiment they decided upon in that connection last year had turned out successfully. The insurance companies were quoting rates which appeared to them out of all proportion to the risks incurred under the new Act. They, therefore, decided to become their own insurers and to place £1,000 to a reserve fund for that purpose, and to put aside a certain sum every week. They had done so, and when they came to reckon up the claims which they had to pay during the year, they were so exceedingly small, that they were able to recredit almost the whole of that sum back into the funds. There was one great change in the balance-sheet, viz., that whereas last year they had large sums as cash in hand, this year they owed considerable sums, the turnover in that respect being something like £100,000. That was accounted for by the fact that they had put £55,956 into extensions of the works; they had spent in wages and material on extra work in hand £31,926; they had increased their investments by £5,300, and they were owed £10,820 more than last year. Those figures gave them a total of £104,002, and the effect of that was that it would be necessary for them to find some means of raising some additional capital to pay for further extensions in the works. The industry had developed to such an extent as to render such a course prudent and advisable. At the present time they had three to five years' work ahead of them and it therefore became the duty of the directors to see what would be the most

Digitized by Google

prudent method of raising the necessary money to carry out these extra extensions at Loughborough. They thought that the time had arrived when they should pay off the remaining 50,000 second debenture stock, which was bearing 4½ per cent. interest, and issue in its place £125,000 4 per cent. debenture stock, which would rank after the existing 4½ per cent. perpetual debenture stock. If they did that, they would obtain £25,000 extra capital at a cost of £500 per annum, in other words, at 2 per cent. They proposed to make that issue about the middle of next month, and they would take care that the present shareholders would have a good opportunity for subscribing for their share of that stock. They were using their best endeavours to spend the money wisely in additions to the works and in endeavouring to avoid creating large shops which would be on their hands if the tide of business should turn. In conclusion, the chairman referred to the new dynamo that the company was introducing—the inductor, in which both the field magnets and the armature coils were fixed. They had, he said, great hopes of the machine, because all who had seen it thought very highly of its mathematical soundness.

Mr. B. H. Van Tromp seconded the motion, and, after some discussion, the report was adopted.

The City of Carlisle Electric Tramways Company, Limited.

The first ordinary meeting of the shareholders of the above company was held at Manchester on the 7th inst. Mr. T. D. Lingard, the chairmen of the company, presided.

The Chairman said in a company of that sort, where a considerable amount of works had to be constructed before the business of the company was commenced there was practically nothing, or very little, to say. Had it not been for the provisions of the Companies Acts, the directors would not have troubled the shareholders to come together on that occasion. He was happy to say that the flotation of the company was in every way satisfactory. The ordinary shares were considerably over-applied for, and the debenture stock had been placed. The engineers of the company had been successful in satisfying both the local authorities and the Board of Trade as to the details of the construction of the Carlisle tramways. The speaker then read reports from the contractors and engineers of the works, from whom it appeared that matters were proceeding in a satisfactory manner. The contractors wrote that the work would be completed up to time, which was December 31st next.

Kalgoorlie Electric Power and Lighting Company, Limited.—The secretary of this company, whose prospectus was contained in our last issue, writes to the *Times* as follows:—

It has been pointed out to me that the wording of the paragraph in the prospectus of the Kalgoorlie Electric Power and Lighting Corporation, Limited, dealing with the report of Prof. George Forbes, F.R.S., may be construed to mean that in addition to having exhaustively reported upon the merits of this undertaking, he also personally made a local examination. My directors do not admit this inference, and it was not so intended, as Prof. Forbes made his report upon materials furnished to him, as explained in the report itself, which can be seen at the office of the company's solicitors.

Stock Exchange Notices.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to—Charing Cross and Strand Electricity Supply Corporation, Limited.—Further issue of 20,000 ordinary shares of £5 each.

Royal Electric Company of Montreal.—The directors have declared a dividend of 2 per cent. for the quarter ended August 31st, being at the rate of 8 per cent. per annum, payable on October 2nd.

W. T. Henley's Telegraph Works Company, Limited.—Letters of allotment and regret have been posted for the issue of the 4½ per cent. preference shares, which was largely over subscribed.

TRAFFIC RECEIPTS.

The Blackpool and Fleetwood Tramroad Company.—The receipts for the week ending September 9th, 1899, were £1,335 17s. 2d.; receipts for week ending September 9th, 1898, £1,112 14s. 5d.; aggregate for half-year to date, £14,798 2s. 7d.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending September 8th, 1899, were £3,697 12s. 8d.; corresponding period 1898, £3,448 1s. 2d.; increase, £254 11s. 1d.

The City and South London Railway Company.—The receipts for the week ending September 10th, 1899, were £886; week ending September 11th, 1898, £876; increase, £10. Total receipts for half-year, 1899, £10,418; total receipts corresponding period, 1898, £10,487, decrease, £69. Miles open, 8½.

The Dover Corporation Electric Tramways.—The receipts for the week ending September 9th, 1899, were £293 13s. 4d.; week ending September 10th, 1898, £244 10s. 8d.; increase, £49 2s. 8d. Total receipts to date, 1899, £7,074 19s. 0d.; corresponding period, 1898, £5,750 1s. 3d.; increase, £1,324 17s. 9d. Miles of track open, 1899, 8; 1898, 8. Car miles run, 1899, 4,916, 1898, 3,807. Number of cars, 1899, 12; 1898, 10.

The Dublin United Tramways Company.—The receipts for the week ending Friday, September 8th, 1899, were as follows:—D. U. T. Co., horse cars, £1,370 3s. 9d.; ditto, electric cars, £2,189 9s. 5d.; D. S. D. Co., electric cars, £1,050 13s. 9d.; total, £4,560 6s. 11d.; corresponding week last year—D. U. T. Co., horse cars, £2,886 5s. 6d.; ditto, electric cars, £604 12s. 7d.; D. S. D. Co., electric cars, £1,213 18s. 8d.; total, £4,704 16s 9d.; decrease, £144 9s. 10d. Aggregate to date, £47,283 15s. 7d.; aggregate to date last year, £45,839 7s. 11d.; increase to date, £1,444 7s. 8d. Worked:—The mileage open is 25 miles electrically, 19 miles by horses, as against 12 miles electrically, and 30 miles by horses, for the corresponding period last year.

The Halifax Corporation Tramways.—The receipts for the week ending September 10th, 1899, were £750. Miles of track open, 10. Car miles run, 11,521. Number of cars, 21. The receipts for the week ending September 14th, 1898, were £306. Miles of track open, 8½. Car miles run, 3,723. Number of cars, 10. Total receipts to date, 1899, from April 1st, 1899, £13,913; total receipts to date, 1898, from June 29th, 1898, £3,188.

The Liverpool Overhead Railway Company.—The receipts for the week ending September 10th, 1899, amounted to £1,614; corresponding week last year £1,528; increase, £86.

The South Staffordshire Tramways Company.—The receipts for week ending September 8th, 1899, were £722 13s. 1d.; aggregate receipts for 36 weeks, £23,840 15s. 10d.; week ending September 9th, 1898, £789 10s. 2d.; aggregate receipts for 36 weeks, £23,657 17s. 5d.

STOCKS AND SHARES.

Wednesday Evening.

A cheerful mind shrinks from the melancholy task that faces it this week in writing the usual Market Notes. Falls have to be recorded in almost every instance where there is any change to report at all. Not that there are very many alterations, however, and some little consolation must be derived by shareholders of the unchanged securities at the strength displayed by their stocks, considering that the Stock Exchange generally has been so shaken in every department. A recovery from its gloomiest mood gave the House more confidence on Tuesday, and it is quite certain that the majority of members will not believe in war until the first shot has been fired by the Boers. Nevertheless, the tension continues, and the heavy fall in the mining markets has caused some realising of electric and kindred shares by people in want of money wherewith to meet their engagements in Kaffirs and Kangaroos.

The electricity supply section has seen its Metropolitan companies' prices sag daily. Citys are exceptional in maintaining their ground, but the market is flabby and dull. Westminsters blazed up at the end of last week, some fairly good buying taking place in a market short of shares, but immediately the broker had been accommodated the quotation slipped back again, and now is even 10s. down on the week.

The Royal Electric Company, a Canadian concern, declares its usual dividend of 2 per cent. for the quarter. The hundred-dollar shares stand at 170, and the price of the 4½ per cent. Debentures is 106. Very little market exists in London for either description of stock, the Montreal Exchange doing what small amount of business there is in them. The company has a contract with the Corporation of Montreal city for electric lighting until 1904, at an average price of about £24 per lamp per annum. We have not yet heard of any proposal to cancel the agreement by the Corporation.

Decidedly interesting is the new Kalgoorlie Electric Power and Lighting Corporation, whose prospectus appeared in our columns last week. The issue of £150,000 Preferred shares of £1 each offers a fair field as a speculative investment. We certainly consider that the purchase price, £25,000 in Deferred shares, is plenty of money, but as the whole of the new emission is to be set aside for working capital, and as the shares issued to the public are preferential, both as to capital and interest, there is not much ground for cavilling. The shares are being dealt in to a small extent by the West Australian mining market, and there is the pro-allotment premium of $\frac{3}{16}$ per share quoted, which we hope will not run off.

Telegraph stocks are inclined to weakness. Eastern Ordinary has shed another brace of points, and now stands lower than it has been since 1894, when the price of the £10 shares fell to 14¾, equal to 147½ of to-day's stock. The fears of fighting in South Africa have led to some inquiry for the stocks of those other African lines which are not likely to be injured by the outbreak of hostilities. West African 5 per cent. Debentures are 1 up. There has been some inquiry for Western and Brazilian 4 per cent. Debenture stock. Anglo-American issues fell upon the news that Cornelius Vanderbilt was dead, it being almost invariably the case that a sudden fall in Yankee rails brings a corresponding drop in Anglo "A" and "B." Otherwise the telegraph market is without feature.

Oriental telephones weakened a trifle at the advent of a small seller. Nationals remain quiescent; the rate for contangoing the shares to-day (Wednesday) has been about 3d., and the making up price 5¼, as against 5⅜ of a fortnight ago.

The Tramways Union Company has voluntarily wound itself up, and nothing remains for the directors to do beyond realising the Bremen asset. As we foreshadowed last week, this will probably mean the return of another 70s. per share to holders. Another company which is thinking of retirement from the toils of public life, is the Paris Omnibus Company, which, it is stated, is considering the offer made by a traction concern that the latter shall take over and electrify the whole of the present tram system in Paris. There ought to be money in the scheme, considering the immense advantage which an electrical service would possess over that at present worked by what are politely called horses.

THE SYNCHRONISING OF ALTERNATORS.*

By M. GARDNER and R. P. HOWGRAVE-GRAHAM.

(*Concluded from page* 417.)

We will now deal with a few of the methods of connection of synchronising apparatus which depend on the same principle as the method just described. In (fig. 4) the primary, P, of a transformer is put where the lamps were in the former case, and one or more lamps are put in series with the secondary, S. This, of course, is for high tension systems, where it is impossible to put lamps straight on to the machines.

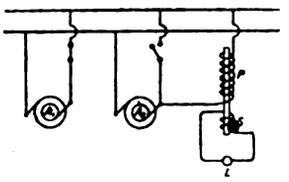

Fig. 4.

Fig. 5 shows a method in which a transformer, with two primaries, is used, one being connected to the bus bars or to A_1, and the other to A_2. This method has the advantage of admitting of the use of a double-pole switch. The arrows show the directions of the electromotive forces and magnetomotive forces at the right moment for

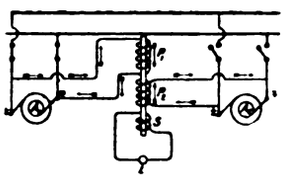

Fig 5

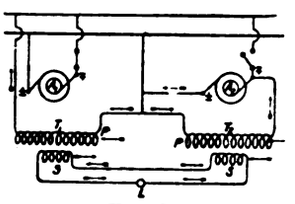

Fig. 6.

switching in. Another way is to have two entirely separate transformers, the primary of one being connected to the bus bars, and that of the other to the machine to be thrown in, as in fig. 6.

If the secondaries are connected in series, the moment for switching in will be that of minimum light. If the secondaries are cross-connected, it will be that of maximum light. The substitution of telephones for lamps was introduced by the General Electric Company. They did not use ordinary telephones but large iron-wire-cored electro-magnets with iron diaphragms in front. They had them quite separate, one to each machine, either with or without transformers, according to the voltage.

These sounders simply howled, and when the machines were getting into synchronism, the sound waves interfered with each other, and beats were produced, rapid at first, but getting slower and slower.

When the note was clear and steady, it was known that the machines were in synchronism, and they were switched in, though they might be ever so much out of phase, and we have spoken of how disastrous this may be. However, it is clear that we can use a single telephone in place of the lamp or lamps in any of the pilot lamp methods described, and that then we may be sure of synchronism and step by switching in when the sound is at a minimum.

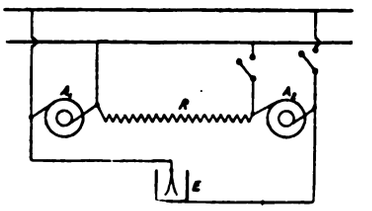

Fig. 7.

I have a telephone here which I can substitute for the lamp in this revolving commutator model. A Cardew voltmeter is a very present help in time of trouble, if used instead of, or even as well as, an incandescent lamp. It reads quite quickly enough, and the exact position of the needle, as it slowly oscillates, is easy to follow, while the exact brilliance of a lamp is difficult to judge, owing to eye fatigue.

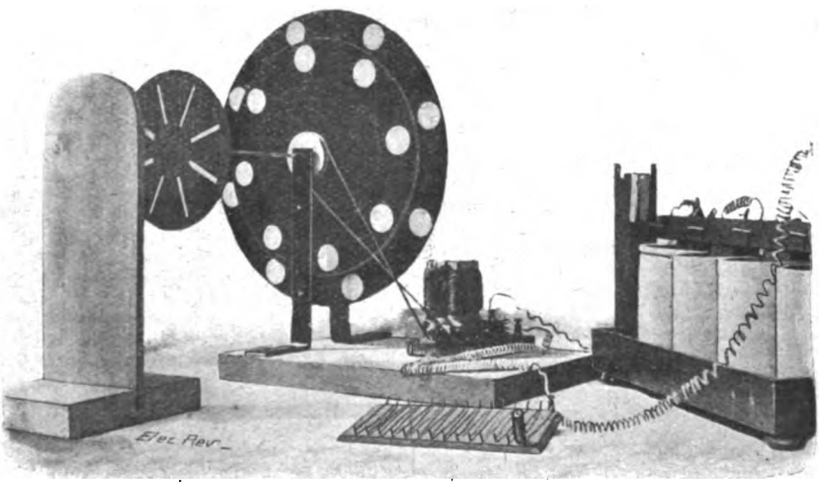

Fig. 8.

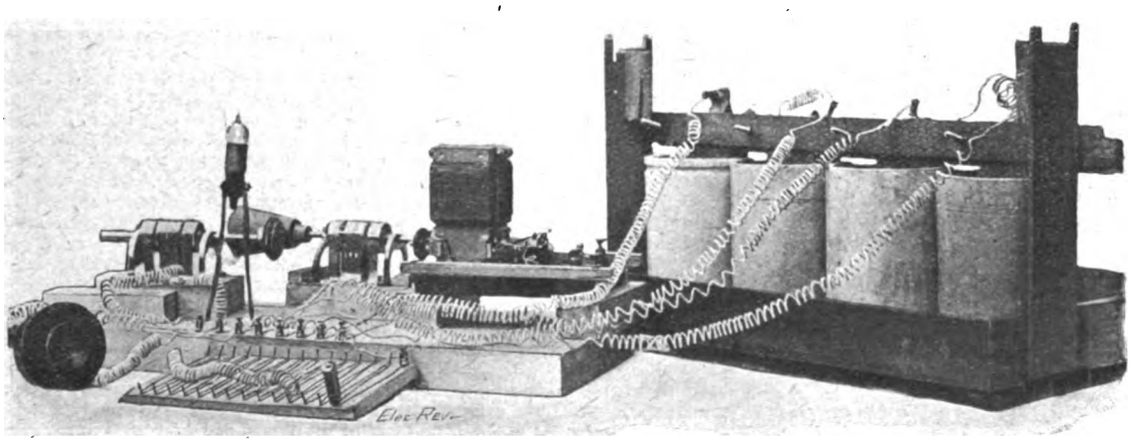
Prof. Ayrton mentioned at the Institution of Electrical Engineers in 1894, an electrostatic synchroniser, for the purpose of doing away with transformers in high tension stations. A diagram of connections is shown on the board (fig. 7):—R was to be a resistance, almost as large as you like, say a thin lead pencil line on a piece of slate or ebonite. E was to be any dead-beat electrostatic voltmeter, such as a gold leaf electroscope, which might be made with leaves even a foot and a half long, to be visible all over the station. In such an apparatus the moment for switching in is when the leaves stay closed



Illustrative Model.—See page 416 ante.

* Read before a meeting of the students of the Institution of Electrical Engineers on Wednesday, March 22nd, 1899.

Digitized by Google

for some time. Prof. Ayrton claimed that an electrostatic arrangement like this is more dead-beat than a lamp, the luminosity of which remains. He maintained, also, that it is cheaper than the ordinary methods, as it does not involve the use of somewhat expensive transformers, and that it may be as large as you like, and needs no accurate calibration and no scale, and, as an electrostatic voltmeter, may be as wrong as you like, and, lastly, that it is perfectly and absolutely safe.

Sometimes little auxiliary synchronising bus bars are provided. Any machine to be synchronised can be connected to them, and the whole thing done as usual, except that when the right moment comes, instead of being switched straight on to the main circuit, it is put on to these bus bars, between which one or more choking coils are placed, through which the machine cannot possibly force more than 10 or 15 amperes. This current is quite sufficient to synchronise it, and when it is seen to be running quietly and steadily it is put on to the main circuit by a second switch.

Optical Synchronisers.

There is a very curious optical effect made use of in synchronising. It was noticed that if the light from an alternating arc fell upon the alternator lighting it, the fly-wheel appeared to stand still or revolve very slowly, according to the number of spokes in it. Now, if we paint the armature, or revolving part, round with as many spots as there are alternations per revolution, and light it from an arc overhead driven by itself (we mean the armature's self, not the arc's), a spot which we will call A, which is in front of one which we shall call B, will be illuminated when the pulsating light is at its maximum. B will also be illuminated as will all the other spots round the armature.

The light will now die down a little, and by the time the next maximum brightness comes, the spot B will have got to where A was before, and all the other spots will have been shifted on one space. The effect of this will be to make the circle of spots appear stationary. If the same arc lamp lights up another machine similarly painted with spots, and if that other machine is being brought into synchronism, and is running a little bit slower, its spots will appear to slowly rotate backwards, because, instead of moving on one space to each beat of light, if we can call it so, the spots move rather less than one space.

This method is never used for absolute synchronising, but mostly to give the man who is at the engine a rough idea of how the speed is going, while there is a man at an ordinary pilot lamp apparatus as well. The things which appear to happen to the spots as the second machine gradually speeds up, are best seen on this model, where the effects are wonderfully like those on a real machine. I will just roughly describe it.

The large disc (fig. 8) represents the machine already running, is painted round with eight equidistant spots, and rigidly connected to a shaft driven by a motor. At the front end of the shaft there is a small disc, in which eight slots are cut. This disc is also rigidly connected to the shaft, and when a light is placed behind the slots, flashes of light are produced, which imitate the light given out by the alternating arc driven by the dynamo corresponding to the large disc.

The disc between the two others is, as you see, painted with similar white spots, but is loose on the shaft, and when the large disc is revolving we can hold it, and on letting it go, observe the effects, as by friction it gradually gets up to synchronism with the large disc. You will see the spots on the large disc appear to stand still, while those on the smaller one will, after various curious changes, appear to slowly rotate in a direction opposite to that of the real rotation. If the friction were great enough they would finally come to rest.

As regards this method, it will be interesting to quote the words of Dr. Silvanus Thompson in the discussion of Mr. Mordey's paper of 1894, before the revolving spots ever came to be used at all. He says:—

"I remember very well watching the machines built by Gaulard & Co. in the station at Rome."

"The alternators were set in one line."

"You can look through one machine at another, and you can see when the machines are synchronised by merely observing the rotating magnets of one machine across the rotating magnets of the other."

"They will appear to be stationary when absolutely in phase, just as two perforated discs of cardboard do with holes, when they are spun round at equal speeds, one being watched through the other."

"It is quite possible, I think, that some optical synchroniser might be found which would be more satisfactory than either acoustic or electrical synchronisers used with lamps."

The authors humbly venture to suggest that what Dr. Thompson foresaw, before the use of revolving spots was known at all, may be sometime more fully realised than it is now, and that optical methods, which are at present quite in their infancy, and only used as rough guides to the man at the engine, may be the methods of the future.

THE ELECTRIC LIGHTING (CLAUSES) ACT, 1899.

This Act, which has been passed for the purpose of incorporating in one Act certain provisions usually contained in provisional orders made under the Acts relating to electric lighting, comes into operation on October 1st, 1899. It consists almost entirely of a schedule comprising rules and regulations in accordance with which undertakers are to supply electricity in the area named for that purpose in any special order of the Board of Trade, and a short clause of incorporation will have the effect of materially shortening any such order. The provisions of the schedule are to be read and construed subject in all respects to the provisions of the Electric Lighting Acts, 1882 and 1888.

The following abstract, which does not claim to give anything more than a bare outline of a long and complicated schedule, will serve to show the general nature of the rules which must be observed by an electric lighting corporation.

After an interpretation clause which defines the various technical terms used in the schedule, the second section provides that undertakers are to be "the authority, company, or other person named for that purpose in the special order." A reference to the Electric Lighting Act of 1888 shows that the local authority in any given area are not only entitled to be undertakers, but that they may, subject to the provisions of Sec. 2 of that Act, purchase compulsorily the undertaking of any private company or person. This power is in no way curtailed by the new Act.

By Section 5, where the undertakers are not the local authority, provision is made for the deposit of a sum of money to the amount specified in the special order by way of security for the due execution of the works. The sum so deposited is to be repaid in equal moieties as soon as it is certified by an inspector that sums equal in amount have been expended on the works by the undertakers.

The 7th Section makes provision for the outlay of monies received by the undertakers—other than borrowed money or capital—in the following order:—

1. Payment of working and establishment expenses.
2. Payment of interest or dividend on mortgages and stock.
3. In providing any instalments or sinking fund.
4. Payment of expenses of executing the special order not properly chargeable to capital.
5. In providing a reserve fund, if they think fit.

If the surplus in any year exceeds £5 per centum per annum upon the aggregate capital expenditure on the undertaking, the undertakers are to make such rateable reduction in the charge for the supply of energy as in their judgment will reduce the surplus to that maximum rate of profit. This enactment will be appreciated by consumers, but the limitation of profit to 5 per cent. will not afford any very strong inducement to private companies to undertake the supply of electricity.

Where the local authority are undertakers a curious provision in Section 8 prevents them from purchasing ten or more houses which, on the 15th day of December last, before the commencement of the Special Order were occupied by the "labouring class."

By Section 10 it is absolutely forbidden for the undertakers to place any electric line above ground except on their own premises, while connection with earth is prohibited unless with the consent of the Board of Trade and the Postmaster-General.

Sections 11—20 deal with the works which the undertakers may effect, and prescribe the various notices to be served before operations are commenced. By Section 14, if they propose to place any works along any street or public bridge, one month's notice must be given to the local authority and the Postmaster-General, who may approve or object. If any objection is lodged the undertakers may appeal to the Board of Trade. Default in meeting with the requirements of this section is visited with a fine of £10, and a daily penalty of not more than £5.

Where streets are repairable by the County Council, and where the proposed works are likely to interfere with any such street, or any railway or canal, it is provided by Section 15 that notices must be served upon the County Council in the former case and in the latter case upon the body or person for the time being entitled to work the railway or upon the owners of the canal as the case may be. Disputes arising with regard to compensation are to be settled by arbitration.

By Section 16 the person or body liable to repair any street, or entitled to work any railway or tramway which the undertakers are empowered to break up for the purposes of the special order, may, after giving the undertakers notice themselves, perform the undertakers' work, in relation to the breaking up, filling in, and reinstating of roads, &c. Thereupon they shall be entitled to execute the works at the request of the undertakers to whom they may also look for expenses properly incurred.

With regard to alterations of pipes, wires, &c., under streets, these can only be made subject to notice having been given to the owner of the pipes and wires [see Section 17]. This provision applies equally for the protection of the undertakers themselves.

By Section 18, the undertakers are required to give three days' notice to gas companies, water companies, and the local authority of their intention to dig or sink any trench for laying down or constructing any new electric lines. A similar duty is imposed upon these bodies when they are about to take up the road. In each case the interested parties are entitled by their officer to superintend the works. Penalties are imposed for the infringement of this clause.

Section 20 contains stringent provisions with regard to the laying of electric lines in such a manner as to interfere with any existing telegraph or telephone wires.

Sections 21—26, which provide for compulsory works, contain some enactments which are of interest to the consumer. The undertakers are compelled to lay down suitable wires, &c., within two years after the commencement of the provisional order. Twenty-eight days before commencing to lay an electric line in any street, they must serve upon the local authority, and the owners and occupiers of the premises adjoining, a notice of their intention so to do. Default in laying mains within the prescribed period may be punished by fine, or in extreme cases by revocation of the special order. A requisition to lay distributing mains may be made by six or more owners of premises along any one street. This may be refused by the undertakers unless the persons making the requisition, in addition to certain other undertakings, guarantee to take a supply of energy for three years.

Sections 27—30, which deal with supply, provide for a continuous supply of electrical energy. "The maximum power with which any

Digitized by Google

consumer shall be entitled to be supplied shall be of such amount as he may require to be supplied with not exceeding what may be reasonably anticipated as the maximum consumption in his premises." Penalties to the extent of 40s. may be imposed upon the undertakers in respect of each day upon which the supply fails—except where it was occasioned by *force majeure* or inevitable accident.

Sections 31—34 deal with the price at which the supply is to be furnished. Quantity supplied may be estimated either:—

1. By the actual amount of energy supplied; or
2. By the electrical quantity; or
3. By such other method as may be approved by the Board of Trade.

The prices to be charged are not to exceed those mentioned in the special order, subject to revision by the Board of Trade.

Electric inspectors may be appointed by the Board of Trade. Their duty will be to inspect the undertaker's lines and works, the meters of consumers, and to undertake any other duties required of them by the special order. Their salaries are to be paid by the local authority.

By Section 36 it is provided that notice of any accident by explosion, &c., is to be sent to the Board of Trade by the undertakers.

Sections 39—48 make provision for the inspection and testing of mains, and also the works and supply on the consumer's premises, for which purpose the undertakers are to provide instruments on their own premises. These tests may be made at all reasonable times by the inspectors appointed in accordance with the provisions of this Act.

Sections 49—59 provide that meters are to be used in all cases, unless otherwise agreed between the consumer and the undertaker. Meters are to be supplied by the undertakers, but must be kept in order by the consumer at his own expense. Where meters are let on hire by the undertakers they must, unless the agreement otherwise provides, keep the meter in order. Any differences as to the correctness of the meter are to be settled by the inspector. Where the method of charge is altered, the undertakers must provide new meters to the consumers.

The undertakers may place upon the premises of any consumer a meter to measure the supply, or to check the measurement of the consumer's own meter.

Sections 61 and 62 make provision for the service of the notices required by the Act, indicating the persons upon whom such documents are to be served. In computing the time within which this duty must be performed, certain holidays and fast days are excepted.

Sections 63—68 deal with the revocation of the Special Order under certain circumstances. It will be revoked under the following circumstances: (1) Where undertakers are insolvent. (2) Where the undertaking cannot be carried on with a profit. (3) Where the local authority are undertakers and the works are not executed; (4) by consent.

By Section 69 it is provided that in certain cases where it is proved (*a*) that the undertakers are supplying energy otherwise than by an approved system; (*b*) that any lines are defective; (*c*) that any work of the undertakers injuriously affects any telegraphic line of the Postmaster-General, the Board of Trade may by order specify the matter complained of, and require the undertakers to abate it, under penalties for delay.

By Section 76 all penalties, &c., and other monies recoverable under the Special Order may be recovered summarily in the manner provided by the Summary Jurisdiction Acts.

Section 77 renders the undertakers answerable for all accidents, damages, and injuries happening through the Act or default of them, or of any person in their employment, by reason of or in consequence of any of the undertaker's works, and imposes upon them the duty of indemnifying all authorities, bodies, and persons by whom any street is repairable and all other authorities, companies and bodies, collectively and individually, and their officers and servants, from all damages and costs in respect of those accidents, damages and injuries.

By Section 79 the Postmaster-General is declared to be entitled to all his rights under the Electric Lighting Acts, 1882—1888, and the Telegraph Acts, notwithstanding that those are in addition to the rights conferred upon him by this Act as incorporated in any Special Order.

By Section 81 it is provided that nothing in the Special Order shall exonerate the undertakers from their common law liability for nuisances.

Subject to certain modifications which are set forth in Sections 83 and 84, the Act is made applicable to Scotland and Ireland.

An appendix incorporates the following Sections of certain public Acts with this Act:—

1. Electric Lighting Act, 1882, Section 12.
2. Gasworks Clauses Act, 1847, Sections 6—12, and Sections 18—20.
3. Gasworks Clauses Act, 1871, Sections 38—42, and Sections 45 and 46.

THE COPPER MARKET IN AUGUST.

Messrs. H. R. Merton & Co.'s statistical report for the fortnight ending August 31st shows that the price of standard copper has advanced 10s. per ton, and that the stocks in European ports or afloat thereto have fallen 630 tons since July 31st. The position, therefore, is slightly less favourable to consumers of the metal than at the commencement of the month. The supplies during August totalled 17,965 tons, against 18,595 delivered, and the stocks on August 31st amounted to 32,389 tons.

The supplies during August from North America and from Chili were below the average of the preceding 12 months, while from all other countries the supplies have exceeded the average. The shipments from "other countries" are less than in July, being 4,245 tons, as compared with 6,767 tons in the previous month; but both of these totals are above the average, and promise well for the future yield of these outside countries.

The relative costs of copper and aluminium, when used as electrical conductors, are now expressed by—

$$\frac{8{\cdot}93 \times 8{\cdot}62 \times 59}{2{\cdot}68 \times 14{\cdot}5 \times 100} = \frac{4,541}{3,886} = \frac{116}{100}$$

Aluminium at 29 cents per lb. (the Pittsburg Company's price for aluminium rods) is, therefore, still considerably cheaper than copper.

The following new copper mining companies have been floated during August:—

Mount Lyall Blocks Copper Corporation, Limited, Capital £300,000.

The capital of this company had been privately subscribed, and the prospectus was published merely for public information. The vendors take £275,000 in shares, and the remaining £25,000 is held as working capital. The property covers 70 acres, and adjoins the North Mount Lyall Company's property in Tasmania. A body of ore 40 feet in thickness has been found, and 121 assays of daily samples taken from the ore face have shown over 10 per cent. of copper. The only report on the property appears to be by Mr. R. Schloesser, M.E., acting for the vendors, the Mount Lyall Blocks Mining Company, of Melbourne. The cost of mining and delivering the ore at Queenstown-Tasmania is estimated in this report at 11s. per ton. Gold and silver are expected to be obtained in payable amounts.

The Caledonia Copper Company, Limited, Capital £750,000.

This company has been formed to purchase and develop two groups of copper ore properties in New Caledonia—the island in the Pacific Ocean. The properties cover an area of over 4,000 acres. The two groups are connected with each other and with the coast by a railway nearing completion. The ores are sulphides. The Pilon property has been extensively developed, and bodies of ore, assaying 8 to 20 per cent. copper, have been located. The Ao property has not yet been satisfactorily opened up, but the indications point to the geological formation being similar to that of the Pilon property. The average value of the ore in sight, *after subjection to hand picking and concentration*, is given as 15½ per cent. copper, 8 oz. silver, and 9 grains gold. An annual shipment of 40,000 tons is estimated, and taking copper at £65 per ton, an annual profit of £265,000, or 35 per cent. on the capital, may be expected.

The International Copper Corporation, Limited, are the vendors, and are realising at a profit. £50,000 is to be appropriated for working capital.

The purchase price is fixed at £700,000 in cash or shares.

Taking the above figures, a simple calculation shows that the estimate of a 35 per cent. return on the capital is based on a profit of £43 per ton of copper contained in the ore. This is too high, and we shall be surprised if the 35 per cent. dividend is ever paid or earned. *If* the International Copper Corporation, Limited, are assured of the latter, would it not pay them to stick to the property?—for 35 per cent. dividends are not very common at the present day.

The Mount Chalmers Copper Mines, Limited, Capital £300,000.

This company has been formed for purchase and development of the Mount Chalmers Copper Mines in Queensland. The properties cover 140 acres, and are situated 20 miles from a railway and 16 miles from the coast. Shafts have been driven through the property, the main body of ore has been located, and 1,500 tons of ore have been brought to the surface. 200,000 tons ore is estimated to be in sight, averaging 6 per cent. copper, 4 ozs. silver, and 6 dwts. gold.

Taking an output of 500 tons ore per week, a smelting plant of this capacity should yield a profit of £78,000 per annum with copper at £50 per ton. The mining and smelting charges should not exceed 22s. 6d. per ton.

Mr. D. W. Blaxter is the vendor, and is re-selling at a profit for £250,000, £175,000 of which is to be paid in ordinary shares and the balance in cash or shares.

In conclusion, we may draw attention to a note in the Foreign Intelligence columns of the *Times* of August 2nd, to the effect that a Russian mining association has obtained a 70 years' lease of a territory which includes nearly all the north of Persia, and is *believed* to contain the richest copper mines in the world.

The Amalgamated Copper Company, of New Jersey, will certainly have to increase its capital to an alarming extent, if any control of all these new producing mines is to be established or maintained.

AUTOCAR TRIALS AT LIVERPOOL.

The recent autocar tests at Liverpool form the subject of some pretty scathing remarks in a contemporary by a writer and an engineer who signs himself "Traction Engine." The gist of these remarks is that the small loads asked for in autocar work are a mistake; that the autocar people are beginning to learn what is now ancient history with traction engine makers, and that road work with steam motors will approach

Digitized by Google

traction engine practice; and finally, to sum up, we may almost say that the problem of road traction would have been solved long ago if it had not been for the very severe restrictions imposed upon the use of traction engines.

The writer goes into considerable detail in his letter in respect of the question of flat tyres and other details, and concludes that progress is being made, and that in a few years' time it may be possible to purchase a really serviceable motor van at half the prices asked for the things now being made. He compares £500 worth of motor van with £500 worth of traction engine greatly to the advantage of the latter.

We think, however, that while there must and will be many errors in the early days of the autocar and similar vehicles, there will be some sound practical outcome in the shape of something different from a traction engine. As to the steam traction engine as now built nothing but admiration can be recorded. It is really a fine sight to see a traction engine sunk up to its axles in soft clay on an irregular surface; to see it fed under its wheels with chunks of timber and watch it climb out of the slough by its own energy. There are few specimens of mechanical engineering that surpass a good strong traction engine. The adaptation of means to an end and the way in which an engine accommodates itself to any sort of surface and climbs banks and obstructions are really marvellous. Roads were made for vehicles to run upon. We fail to see that gas and water mains should be allowed to limit the user of the road surface, because gas companies are so busy diluting their product with hydrogen and carbonic oxide—we apologise, we should say water-gas—that they have no time to place their pipes properly. The traction engine makers have met their problem by slow speeds and heavy loads, and if freed from unreasonable restrictions, an immense field would be laid open for their use. But this does not dispose of the fact that there is a need for lighter vehicles also. We are inclined to doubt the value of the small-tube boiler for the work of the autocar. There are many curious feed waters likely to be put into the tank of a road engine. This cannot be guarded against. How will small bent tubes act with such waters, often excessively sedimentary? "Traction Engine" very properly animadverts on the placing of working parts or undergear within 5 inches of the ground. This, of course, cannot be admitted; it cannot endure, and with many other crudities must be eliminated from autocar work.

Such letters will do good. Criticism of a fair nature will not kill. Autocarists have much to learn, and if in earnest will welcome technical criticism.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

In view of the meeting of the British Association for the Advancement of Science now proceeding, the reports of the convention of the American Association, held at Columbus from August 21st to 26th, possess a special interest. During the meeting there were 273 papers read, a large number being on electrical subjects. The president was Dr. Edward Orton. We are indebted to the *Electrical World and Engineer* for the following abstract of his inaugural address, as well as for the papers which are also briefly summarised below:—

Dr. Orton reviewed the progress of science and its effect upon civilisation since the human race "first found itself." He looked back so comprehensively and with such a clear mental vision from the closing year of the present century, and compared the 19th century with all past time so ably that much of the final success of the meeting is attributable to his masterly address. White haired and trembling with age, after 50 years of devotion to the progress of human knowledge, yet preserving all those graces that fit him to preside over a deliberative body, the effect of his presence on that occasion was impressive. His language was so simple and well chosen that it would be hard to find a twelve-year-old boy who would not have listened to and understood perfectly what he had to say. Dr. Orton said that the next century seemed destined to show the rounding out of medicine into an exact science; a better knowledge and use of the laws of energy; a nearly perfect understanding of the phenomena of electricity and magnetism; and some comprehension of the mystery of life itself. What is needed to-day in science are builders as well as analysts, for the most useful truths are the great ones, and the new ones destined to be discovered will be arrived at by putting together some of the dry technical facts of which science is full to-day. He said in part:—

"Our contributions to science are often fragmentary and devoid of special interest to the outside world. It is possible that we could make ourselves more interesting to the general public if we occasionally foreswore our reserve and spent a portion of our time in re-stating established truths. We do not always know the real significance of what we have in hand. A fact or an observation that we may put on record here may have in reality a different significance than the one we are disposed to give it, and consequently may have far more importance than we recognise. But every fact has a place in the great temple of knowledge, and the wise master builders, some of whom appear in every generation, will find them and use them all, and then only will their true value come to light. The field which is the world was never so white to the harvest as it is now, but it is still early moving on the dial of science."

After President Orton's address the association divided into sections as scheduled, in order to facilitate special work in each of the various departments of science. There were nine vice-presidential addresses, each before its respective section.

Prof. C. M. Woodward, of Columbia University, was elected president, to succeed Dr. Orton at the 1900 meeting, which is to be held in New York City.

An Apparatus for the Demonstration of the varying Currents in the Different Conductors of a Rotary Converter.—By Prof. F. C. Caldwell, Ohio State University.
